THE ENCYCLOPEDIA AMERICANA

DEPARTMENT AND ADVISORY EDITORS

ASTRONOMY
SIMON NEWCOMB, Ph.D., LL.D., D.Sc
Astronomer
Washington D. C.

PHILOSOPHY
JAMES E. CREIGHTON, A.M., Ph.D.
Professor of Philosophy, Cornell University
Ithaca, N. Y.

PHYSICS
ROBERT S. WOODWARD, Ph.D., LL.D.
President Carnegie Institution
Washington, D. C.

PURE MATHEMATICS
CASSIUS J. KEYSER, M.A., Ph.D.
Adrain Professor of Mathematics
Columbia University, New York

ARCHITECTURE AND THE FINE ARTS
RUSSELL STURGIS, F.A.I.A.
New York City

ZOÖLOGY
DAVID STARR JORDAN, Ph.D., LL.D.
President Leland Stanford Jr. University
Palo Alto, Cal.

LITERATURE
EDWARD EVERETT HALE, S.T.D.,
Boston, Mass.

CLASSICAL LITERATURE
JAMES HAMPTON KIRKLAND, Ph.D., LL.D.
Chancellor Vanderbilt University
Nashville, Tenn.

EDUCATION
ANDREW SLOAN DRAPER, LL.D.
Commissioner of Education, State of New York
Albany, N. Y.

HISTORY OF THE UNITED STATES
(Vol. XV)
ANDREW C. McLAUGHLIN, A.M.
Editor "American Historical Review"
Carnegie Institution, Washington, D. C.

RELIGION AND THEOLOGY
SYLVESTER BURNHAM, D.D.
Dean of Hamilton Theological Seminary
Colgate University, Hamilton, N. Y.

CHEMISTRY
ALLAN DOUGLAS RISTEEN, Ph.D.
Hartford, Conn.

MINERALOGY
GEORGE LETCHWORTH ENGLISH
Member Association for the Advancement of Science
New York City

ELECTRICITY
WILLIAM MAVER, Jr., C.E.
Consulting Electrical Engineer
New York

ENGINEERING AND MACHINERY
WILLIAM MOREY, Jr., C.E.
Consulting Civil and Mechanical Engineer
New York

RAILROADS
EDWARD S. FARROW
Consulting Railroad Engineer New York

MEDICINE
SMITH ELY JELLIFFE, M.D., Ph.D.
Editor "Medical News" New York

LAW
HENRY M. EARLE
Attorney at Law, New York

ROMAN CATHOLIC TOPICS
P. A. HALPIN
Emeritus Professor of Metaphysics and Ethics

CANADIAN EDITORS

GEORGE McKINNON WRONG, A.M.
Professor of History, University of Toronto
Toronto

CHARLES WILLIAM COLBY, A.M., Ph.D.
Professor of History, McGill University
Montreal

A Few of the Leading Articles in Volume One

WRITTEN AND SIGNED BY SPECIALISTS

ABNORMAL PSYCHOLOGY	ISAAC M. BENTLEY Assistant Professor of Psychology, Cornell University

AMERICAN STREET RAILWAYS — EDWARD S. FARROW
Consulting Railroad Engineer, New York

AMERICAN UNIVERSITY, THE — EDWARD DELAVAN PERRY
Columbia University, New York

ANALYSIS SITUS — PAUL WERNICKE
Professor of Mathematics, State College of Kentucky

ANATOMY — SMITH ELY JELLIFFE, M.D.
Editor 'Journal of Nervous Diseases'

ANATOMY, COMPARATIVE — EDWIN GRANT CONKLIN
Professor of Zoology, University of Pennsylvania

ANATOMY OF PLANTS — HERMON THEODOR HOLM
Expert Botanist, Washington, D. C.

ANT — A. S. PACKARD
Late Professor of Zoology, Brown University

ANTHROPOLOGY, AMERICAN — W. J. MCGEE
Smithsonian Institution

APOLOGETICS — GEORGE WM. KNOX, D.D.
Professor of Philosophy and History of Religion, Union Theological Seminary

APPALACHIAN AMERICA — W. G. FROST
President Berea College

APPENDICITIS — JOHN B. DEAVER, M.D.
Specialist, Philadelphia, Pa.

AQUINAS, SAINT THOMAS, PHILOSOPHY OF — WILLIAM TURNER, S.T.D.
Saint Paul Seminary, Saint Paul, Minn.

ARCHÆOLOGY, AMERICAN — CHARLES CONRAD ABBOTT, M.D.
Archæologist

ARCHITECTURE AND AMERICAN ARCHITECTURE — RUSSELL STURGIS, F.A.I.A.
Author of 'Dictionary of Architecture'

ARCHITECTURE, EDUCATION IN — HENRY R. MARSHALL
Fellow American Institute of Architects, New York

ARISTOTLE — JAMES E. CREIGHTON
Professor of Philosophy, Cornell University

ARISTOTELIANISM — WILLIAM A. HAMMOND
Professor of Ancient and Mediæval Philosophy, Cornell University

ARITHMETIC — DAVID EUGENE SMITH
Professor of Mathematics, Teachers' College, Columbia University

ARIZONA — F. W. HODGE
Smithsonian Institution, Washington, D. C.

ARKANSAS — U. M. ROSE
Ex-President American Bar Association

ARMAMENT OF THE WORLD — CAPT. EDWARD S. FARROW
Late Assistant Instructor of Tactics at the United States Military Academy

ARMY AND NAVY — ALFRED T. MAHAN
Author of 'Influence of Sea Power' etc.

ARMY OF THE UNITED STATES, THE — H. C. CORBIN
Major-General and Adjutant-General, U. S. A.

ARMY AND NAVY MANEUVERS — COL. W. A. SIMPSON
Asst. Adjt.-Gen. U. S. Army

ARMY TRANSPORT SERVICE — WILLIAM H. CARTER
Brigadier-General General Staff

ART — CHARLES H. MILLER, N.A.
Municipal Art Society, New York

ARTHROPODA — A. S. PACKARD
Late Professor of Zoology, Brown University

ASSEMBLAGES — CASSIUS J. KEYSER
Adrian Professor of Mathematics, Columbia University

ASSOCIATION OF IDEAS — ISAAC M. BENTLEY
Assistant Professor of Psychology, Cornell University

ASSYRIOLOGY — IRA M. PRICE
Professor of Semetic Language and Literature, University of Chicago

ASTRO-PHOTOGRAPHY — F. S. LUTHER
Of Trinity College

ASTRONOMY; ASTRONOMY, HISTORY OF; ASTRONOMY, PRACTICAL; ASTRONOMY, THEORETICAL — SIMON NEWCOMB
Astronomer and Scientist

ASTROPHYSICS — S. A. MITCHELL
Department of Astronomy, Columbia University

KEY TO PRONUNCIATION.

ä	far, father
ā	fate, hate
a or ă	at, fat
ã	air, care
a̤	ado, sofa
â	all, fall
ch	choose, church
ē	eel, we
e or ĕ	bed, end
ė	her, over: also Fr. *e*, as in *de; eu*, as in *neuf;* and *oeu*, as in *boeuf, coeur;* Ger. *ö* (or *oe*), as in *ökonomie*.
ẹ	befall, elope
ẽ	agent, trident
ff	off, trough
g	gas, get
gw	anguish, guava
h	hat, hot
h or H	Ger. *ch*, as in *nicht, wacht*
hw	what
ī	file, ice
i or ĭ	him, it
ị	between e and i, mostly in Oriental final syllables, as, Ferid-ud-din
j	gem, genius
kw	quaint, quite
ṅ	Fr. nasal *m* or *n*, as in *embonpoint, Jean, temps*

ñ	Span. *ñ*, as in *cañon* (căn'yŏn), *piñon* (pēn'yŏn)
ng	mingle, singing
nk	bank, ink
ō	no, open
o or ŏ	not, on
ô	corn, nor
ȯ	atom, symbol
ọ	book, look
oi	oil, soil; also Ger. *eu*, as in *beutel*
ö or oo	fool, rule
ou or ow	allow, bowsprit
s	satisfy, sauce
sh	show, sure
th	thick, thin
t͟h	father, thither
ū	mute, use
u or ŭ	but, us
u̇	pull, put
ü	between u and e, as in Fr. *sur*, Ger. *Müller*
v	of, very
y	(consonantal) yes, young
z	pleasant, rose
zh	azure, pleasure

' (prime), " (secondary) accents, to indicate syllabic stress

INTRODUCTORY.

THE publication of a great reference work like the ENCYCLOPEDIA AMERICANA is an undertaking of such supreme importance and responsibility that the reasons and purposes which have inspired the publishers and editors to undertake its production, at such great expense and involving so many years of preparation, should be briefly summarized.

First.— After surveying the encyclopedic field very carefully the publishers of the AMERICANA were convinced that no work had as yet appeared which gave to America — her history, literature, biography, geography, industries and commerce — that thorough and careful treatment which the rapidly advancing life and importance of the nation made imperative. They also believed that the time was auspicious for the production by Americans, who alone could appreciate and faithfully represent the life, thought, and need of their own country, of a National Work — so broad, comprehensive and genuinely great that it would everywhere be recognized as the product of native genius, and be acknowledged worthy of the great people for whom it was prepared. This was the Ideal, and upon this foundation the whole superstructure has been built, the result being the natural and harmonious development of the entire sixteen volumes, because for the first time a sustained and systematic attempt has been made to make a distinctively American encyclopedia. It naturally follows, therefore, that the AMERICANA differs from all other similar productions, and it is this difference which makes it superior as a reference work of information for the American people.

Second.—The AMERICANA is designed to give complete and practical information. Its scope is universal — there is absolutely no subject that should be included in such a work that does not find its place somewhere in the AMERICANA, but the practical utility of the work has constantly been kept in view, with the result that the relative importance of subjects, both foreign and American, has been most carefully gauged by the editors, rendering the AMERICANA of the greatest practical service. All modern encyclopedias have followed, to a greater or less degree, the path marked out by earlier works, omitting much of present-day interest, and continuing second-rate topics of little or no importance. The AMERICANA has not hesitated to make a new departure and eliminate this dead-wood, and in its place the reader will find hundreds of important topics treated that are not even mentioned in other works, besides a great amount of what might be called miscellaneous information, including biographical and geographical names, actual and legendary characters in fiction, notable buildings, works of art, books, plays, operas, etc. It will be seen therefore, that the AMERICANA contains more subjects of living practical interest to Americans than any other encyclopedia in existence. The maps and illustrations have been prepared especially for the AMERICANA at a large expenditure, and they will be found so numerous, correct, interesting and helpful as to lend great charm and value to the work.

Third.— The AMERICANA is designed to be the standard authority in this country upon all subjects covered in its pages. No existing source of information has been relied

upon. Important articles are written by America's leading scholars and authorities, and are signed by their respective authors, so that the reader knows at once the source of his information. Every department has had the active editorial supervision of men eminent in their professions in this country, and it is largely to the untiring devotion and the intelligent work and advice of the associate editors on the staff that the Americana owes its majestic originality of conception and treatment, and the marvelous success which has attended every stage of its production. In this connection the acknowledgment of publishers and editors is due to the more than one thousand contributors to the Americana for the generous and patriotic manner in which they have responded, giving their time and invaluable service in order that America might have a thoroughly representative encyclopedia. The Americana represents, to a far greater extent than any other reference work, the authority of American scholarship and successful practical experience, and must prove indispensable for the daily use of the scholar, the statesman, the student, the professional or business man, and especially to the home circle.

Fourth.—The articles of the Americana are written in a style to commend it to the judgment of all. Clear, concise, comprehensive and attractive, the seeker for information will find the pages of the Americana a perfect delight, so different from the heavy, dull encyclopedic style, while the ease and convenience with which it may be consulted, the fulness of its cross-references, and the richness and recency of its information render it the most useful, valuable, and popular work yet offered to the American public.

While not ignoring the lessons to be learned from the great works of the past and present, the Encyclopedia Americana has independently made its own way along new lines, profiting both by the excellencies and defects of its predecessors and contemporaries, and it stands to-day the Twentieth Century's monument to American genius, scholarship, and energy.

Believing therefore that the Encyclopedia Americana represents in its plan and purpose, its arrangement and treatment, its scholarship and authority, an advance upon all former reference works, it is respectfully dedicated by its editors to the American people, whose life and progress it so fully and faithfully portrays.

Frederick Converse Beach

THE ENCYCLOPEDIA AMERICANA

A the first letter of every alphabet except the old German or Runic and the Ethiopian: the « futhark » of the former places it fourth, the latter makes it thirteenth. As all alphabets ultimately come through the Phœnician (witness the name itself), this arrangement is natural. Our own is inherited from the Latin, which was derived from the Greek; and the latter in its *alpha* confirms its traditional derivation from the Phœnician where and in Hebrew it is called *aleph*, Aramaic *alph*. The name is said to have meant « ox,» and so strongly resembles the root-element of eleph-ant that there is little doubt the original meaning of both was the same. Hence formerly the shape of the lower-case a was derived by some from the rough outline of an ox-head with its horns; but in fact, as evidenced by a comparison of the gradual evolution of forms, the small letters in all cases are derived from the capitals, and the Greek capital A (see table under ALPHABET) in its original shape was a somewhat more cursive form of the Phœnician aleph, which itself was a conventionalized form of the Egyptian hieratic, and that in turn (the final step backward) was conventionalized from the picture of an ibis in the ancient Egyptian hieroglyphics or ideographs.

The sound of the letter has varied little more than the form — perhaps less — except in modern English, which owing to its composite character has made it a symbol of so many different vowel-sounds as to be well-nigh meaningless. Yet even here most of them have never quite lost connection with the earlier vocal efforts it stood for, and their fluctuations are fixed by the character of the vocal opening. The Phœnician sound represented by the letter aleph cannot have corresponded to the Greek alpha or any of its derivatives, as the former alphabet assumed that all syllables began with consonants, and aleph was in some sort consonantal; but the Greeks made it a pure vowel, the so-called « Continental » or broad *a* as in « ah.» This is the simplest and most fundamental of all vowel-sounds, the earliest uttered by infants,— whence many grotesque theories of its divine origin and the reasons for its position,— since it results from opening the throat and mouth wide and emitting the tone from the larynx, with the least friction or interference possible from the other organs; and it is still the most general on the Continent of Europe. But even there it has been largely flattened by the French into the short sound as in « at »; at the end of words in all languages the dropping of the voice tends to slur it toward the sound of u in « but,» which in English it quite attains; and with us it has become the representative of nine distinct sounds, seven of them each recognizably developed from one of the others, and all from the parent sound, while two are of a different order, yet still explicable. The usual arrangement (« fate, fat, far, fall,» etc.) is entirely misleading, as it obliterates this evolution, which the following makes clear:

(1) *a*h, explained above.

(2) *a*ll, a closer sound than (1), formed by drawing back the tongue, compressing the sides of the throat, and speaking more toward the diaphragm. In general utterance this is perhaps the first change from *ah*. It is almost universal among the Hindu and Persian masses (« ghaut » for ghät, etc.), and was very common in England and America in the 18th century: witness pronunciations like « spaw » for « spa »; the curious aberrant « vawz » for vahz, which has more curiously become accepted as a sort of social touchstone in a small group; family names like R*a*leigh, Dec*a*tur, T*a*ney, etc., in American pronunciation.

(3) w*a*s, wh*a*t. The same pronounced still deeper in the diaphragm, and cut short instead of prolonged.

(4) ov*a*l. This is the «neutral» sound, corresponding to « short u »; used in Western languages only in unaccented syllables, and made by lazily opening the organs as little as possible and putting no stress on the expiration of the breath. It is the closest of the vowel-sounds, and the most diaphragmal, and therefore seemingly the antithesis of « broad a »; it has in truth no special relation to that more than to *e* and *o* (« sil*e*nt,» « apr*o*n »), but is the common

weakened form of all. In Hindu speech it is used stressed, as in the familiar « Juggernaut » (Jaganath), « Buckergunge » (Bakarganj), etc.

(5) *bare*. An opener sound than (1), formed in precisely the same manner as (2) except by expanding instead of contracting the throat.

(6) *at*. Identical with (5) except being cut short instead of prolonged; in fact, its short sound.

(7) *ask*. Always a different sound from the others, but not always the same in itself. With the less cultivated speakers it is nearly identical with (5), even with (6). With others, anxious to avoid this flatness and exaggerating in the opposite direction, it is made identical with (1). With the majority of good speakers it is akin to (1), but shorter and more diaphragmal, and with the organs rather closer together.

(8) *any, many*. This is not one of the group of *a*-sounds, but is « short e.» The change was caused by assimilation of the *a*-sound to the *i*-sound of the closing letter.

(9) *ate*. This, in usual order the first given, considered the typical English *a*-sound, and actually furnishing the pronunciation of that letter in its alphabetic position, is not merely not an *a*-sound at all, but not even a simple vowel-sound, being nearly ĕĭ, sliding quickly from a closer and more diaphragmal « short e » to a vanishing sound of « short i.» As in (8), the cause appears to have been originally assimilation with a final vowel (the sonant *e* now so often silent but « lengthening » the *a* before it), and afterwards extended to words where this principle could not act.

A, in general, the first term of any series.

In music, the first note of the scale of A, major minor; and A minor is the relative (or related) minor of (or belonging to) C major; the Continental *la*. The open second string of the violin sounds it, and the instruments of an orchestra are all tuned to it.

In logic, the universal affirmative (« all trade is barter »), distinguished from the particular affirmative (« some trade is barter »). See Logic.

In algebra, the first letters of the alphabet, *a, b, c*, etc., are used to denote known quantities, while the last, down to *z*, denote the unknown,— *a* and *x* being used first in all cases, the others being added according to need.

In geometry and mechanical diagrams, the capitals A, B, C, etc., are used to mark off points, lines, angles, and figures; in complicated diagrams, often supplemented by the small letters and accented, to indicate closer relations of parts.

As an abbreviation see Abbreviations.

As an adjective or attributive, shaped like the letter A; as, an A tent.

A, word. (1) The form of « an » used before consonants. (2) Broken-down form of « on,» or ellipsis of « for a » (« twice a day »). (3) Old form of « ah,» as a war-cry (« A Douglas! »).

A1, ā-one' (colloquially, «first-class»), the mark for highest-grade wooden vessels in Lloyd's (q.v.) «Register of Shipping.» **A** refers to hull, 1 to rigging and equipment. This rank is assigned by Lloyd's surveyors to new ships for a term of years (prefixed to the symbol, as 10A1) dependent on quality of materials and mode of building; but to retain it they must be periodically resurveyed, and if fit are granted continuation for one to eight years, marked 10A1 Cont. 5A1, etc. **A** in red means over-age, but still fit for any voyages which perishable goods can endure; **A** in black, fit for short trips with similar goods. In all cases the 1 is omitted if rigging, etc., are inferior. Iron and steel vessels have a Gothic **A** preceded by numerals from 100 down, 100**A** to 90**A** resurveyed once in four years, 85**A** and below once in three; rigging, etc., marked same as on wooden ships. In the German Lloyd's **A1** and **A** are the two best grades of wooden ships; **B1, B, CL,** and **CK,** lower ones; iron and steel ships are marked as in the English classification, but with the resurvey term marked under the **A**.

Aa, ä («water»: a general Indo-European word in various shapes,— Ger. *ach* or *aach* in Aachen, Biberach, etc.; Lat. *aqua*, pl. *aquæ*, whence O.F. Aigues, Mod.F. Aix, in compounds; etc.), the name of some forty streams in northern and central Europe: among the chief, a French river rising in dept. Pas-de-Calais, flowing into dept. Nord, and reaching the Strait of Dover at Gravelines; about 50 m. long, navigable below St. Omer, and connected with Calais and Dunkirk by canals.

Aachen, ä'Hen. See Aix-la-Chapelle.

Aahmes I., ä'mess, the founder of the 18th dynasty in Egypt, c. 1600 B.C., and its final liberator from the Hyksos or Shepherd Kings, Asiatic nomads who had conquered the land a century or two before. Native kings had already recovered it in part; but Aahmes captured the last Hyksos fortress, Hatwaret (Awaris), expelled them from Egypt, and followed them into southern Palestine, besieged their army five years in "Sharuhen" and captured it. He then penetrated farther into Palestine, levying tribute on it and on the seaboard. This began a long series of Egyptian retaliatory expeditions into West Asia and a long dominance over it. He had an admiral of the same name, whose self-laudatory inscription on his tomb is a most valuable mine of knowledge on the military and naval operations of the time. Aahmes-Nefertari was his queen: her mummy-case, one of the most magnificent ever discovered, is in the museum at Gizeh.

Aahmes II., the **Amasis** of Herodotus, fifth Pharaoh of the 26th dynasty, c. 570–526 B.C. An officer of Apries headed a revolt against him, and overthrew and killed him. Though he seems to have risen from the ranks, and to have loved roystering and disliked royal etiquette, he made a capable and judicious sovereign; saved Egypt from conquest by Nebuchadrezzar (who ravaged it, but retreated), and managed to preserve it from invasion by Cyrus the Great. He was on very friendly terms with the Greeks: lending his influence to promote their commerce and colonization; assigning them the excellent port of Naucratis, which soon grew into a flourishing city; contributing liberally toward the rebuilding of the burned temple at Delphi; and according to Greek story having cordial relations with several philosophers and princes — Pythagoras, Polycrates, etc. Under the reign of Aahmes Egypt enjoyed much prosperity.

Aalborg, âl'bork («eel-town»), Denmark, the chief city of N. Jutland; on the S. side of the Limfjord (a sea-arm which joins the Cattegat to the North Sea), and on the Danish State Ry., which crosses the fjord by an iron bridge 1,250 feet long, one of the finest pieces of engineering in the kingdom. An important commercial town as far back as the 11th century (Wallenstein sacked it in 1627, the Swedes in 1644 and 1657), despite a shallow harbor it still has much trade, by means of small vessels, with Scandinavia and England; while its manufactures — distilleries, leather, lumber, soap, cement, cotton goods, etc.— are now building it up with great rapidity. A bishop's seat, it has a cathedral; also two old churches and an old castle, a museum, and a library of 30,000 volumes. Pop. (1890) 19,503; (1901) 31,462.

Aalesund. See ALESUND.

Aali Pasha, Mehemed Emin, ä-lē' pä-shä', mĕ-hĕm-ed' ā-min', a Turkish statesman: b. Constantinople 1815; d. 6 Sept. 1871. Entering public life at 15, he was chargé d'affaires at London 1838, ambassador to Great Britain 1841–4; chancellor of the divan 1845; thrice minister of foreign affairs in the troublous years 1846–52; grand vizier a short time in 1852, but soon displaced as not in political accord with his companions. Recalled as foreign minister during the Crimean war of 1854, in March 1855 he took part in the treaty of the «four guarantees»; in July again became grand vizier, and at the Treaty of Paris in 1856 showed great decision and cleverness in looking after Turkish interests, but without entire success. November 1 his political tone forced him to resign, but he remained minister without portfolio, and member of the Great Council. After Reshid Pasha's death in 1858 he was again grand vizier, and soon again withdrawn; but in November 1861 he resumed the office of foreign minister. He was president of the convention on Rumanian affairs 1864, and member of the Black Sea Conference in London 1871. During the Sultan's absence at the Paris Exposition in 1867 he was regent; and while the very soul of the reform movement energetically suppressed the Cretan rebellion and the movement for Egyptian independence. In the full tide of activity he suddenly died,— an excellent man and statesman who wasted his life trying to vitalize and purify a body of death.

Aar, ar, **Alex,** pseudonym of Anselm Rumpelt, German poet: b. Chemnitz, Saxony, 10 Feb. 1853. His best work was in historical lyrics, collected as 'Will-o'-the-Wisps' (1878).

Aar or **Aare,** ar («river»), the name of several German streams: chiefly, a Swiss river tributary to the Rhine, about 175 m. long, the largest in Switzerland save that and the Rhone. Formed by torrents from the vast and famous Oberaar and Unteraar glaciers of the Bernese Alps in E. Bern, it flows N.W. through the romantic valley of Hasli, over the celebrated Handeck Falls, 200 feet high, expands into Lake Brienz, and then past Interlaken into Lake Thun, becomes navigable, passes Bern, turns N. and then N.E. along the southern slopes of the Jura past Solothurn and Aarau, and, joining the Limmat, shortly after breaks through the ridge and empties into the Rhine at Waldshut. Chief affluents, the Saane, Zihl, and Emme, the Reuss feeding it from the lake of Lucerne and Zuger See, the Limmat from the lake of Zurich, and the Lütschine from the two splendid Grindelwald glaciers.

Aarau, ar'ŏw («Aar-meadow»), Switzerland, capital of Aargau; right bank of the Aar, 41 m. N.E. of Bern, 1,100 ft. above sea-level, in a fertile plain just south of the Jura, whose peaks close by are the Wasserfluh (2,850 ft.) and Giselahfluh (2,540 ft.). It has famous manufactures of cannon, bells, and fine scientific instruments, besides cutlery, leather, silk, and cotton; and holds eight fairs yearly. There are also historic, scientific, and ethnographic museums, a cantonal library of 89,000 volumes rich in Swiss history, and a bronze statue of the historian and novelist Heinrich Zschokke (q.v.), who lived here. Here, December 1797, the old Swiss confederacy held its last session; April to September 1798 it was the capital of the Helvetic Republic. Pop. (1901) 7,824.

Aardvark, ärd'värk (Dutch, «earth-pig»), the Cape ant-eater (*Orycteropus capensis*). Also called ground-hog and ant-bear. A South African mammal measuring about five feet from end of tubular snout to tip of long naked tail. It lives in shallow burrows and is of timid, nocturnal habit; it feeds on ants and other insects, licking them up with a long tongue which secretes a sticky saliva. The head is slightly pig-like, with erect ears; the stout body is sparsely covered with short stiff hairs; the limbs are short, with strong claws for digging; the flesh is edible and considered delicate, though of peculiar flavor. See ANT-EATER.

Aardwolf (Dutch, «earth-wolf»), a timid, nocturnal South African carnivore (*Proteles lalandii*), the only representative of the family *Protelidæ*. It resembles the hyena, to which it is closely related, but has less strength of jaw and teeth. Its fur is coarse; color, ashy-gray irregularly striped with black; muzzle, black and nearly naked; ears, brown outside, gray within. It inhabits burrows, and being unable to kill vertebrates lives upon insects, larvæ, and small carrion.

Aarestrup, Emil, â'rē-stroop, Danish poet (1800–56). He was not duly appreciated until after his death, but is now acknowledged one of the foremost lyric poets of Denmark, ranking next to Christian Winther. His 'Collected Poems,' with critical sketch by G. Brandes, was published at Copenhagen in 1877.

Aargau, ar'gŏw («Aar-shire»: Fr. Argovie, ar-gō-vē), Switzerland, an extreme N. canton between Basel W., Zurich E., Luzern S., and the Rhine and Baden N. Area, 543 sq. m.; capital, Aarau. It consists mainly of spurs of the Alps and Jura, nowhere over 3,000 ft. above sea-level, with numerous fertile valleys watered by the Aar and its S.E. tributaries, the Limmat (or Linth) and Reuss (see AAR) being chief. The climate is moist and variable, and stock-farming and agriculture are advanced: fruit, vegetables, and vines abound, but the wines are inferior. Timber is plentiful. Manufactures: cottons, silks, ribbons, linens, hosiery, straw-plait, etc., and important machine works. The boat traffic on the Aar and Rhine, and the active land and water transit trade, employ

many. It has several picturesque ruined castles. Aargau, part of old Helvetia, then conquered by the Franks (5th century), a Hapsburg fief 1173-1415, then captured by the cantonal league and divided between Bern and Luzern, was split up and a part made a member of the Helvetic Republic 1798. Its constitution was first fixed by the Congress of Vienna in 1815; in 1831 it gained a democratic one, and has ever since been a champion of liberalism. In 1841 it suppressed its eight monasteries, and this led to the formation of the Sonderbund (q.v.), or Secession League, of Catholic cantons in 1847. Legislative power is vested in the Great Council, one for every 1,100 people, which has to submit laws and decrees to a referendum; executive power in the Small Council of seven, chosen by and from the Great one. Pop. (1900) 206,460, nearly all German.

Aarhuus, âr'-hoos, Denmark. (1) District, the E. central part of Jutland, divided into Aarhuus and Randers *amts* (or bailiwicks); area, 1,821 sq. m.; pop. about 325,000, mainly employed in fishing industries. (2) City, the second largest of Denmark, capital of Aarhuus amt, on a bay of the Cattegat and the Danish State Ry.; has a harbor made in 1883–90, with a breakwater and six feet of water, regular steamer lines to Copenhagen and England, and a large trade in grain, cattle, etc.; and much shipbuilding, iron-founding, cotton-spinning, and other manufactures, which are giving it rapid growth. It is a bishop's seat, and has been such since 948, making it one of the oldest cities in Denmark; and its cathedral, begun in 1201, is one of the largest and finest church buildings in the kingdom. It has a museum also. Pop. (1890) 33,306; (1901) 51,909.

Aaron, a prominent but subordinate figure of the Exodus period in Jewish history, whose importance increases with the distance of the recorder from the early epochs, and with the remodeling of the early histories by the priesthood to support their later pretensions and their theocratic ideal of Judaism. In the earliest or Elohistic (q.v.) portions of the Hexateuch, he is brother of Miriam (Ex. xv. 20); but it is Joshua who is Moses' minister for religious rites and who keeps guard over the tent of meeting (Ex. xxiii. 11), the young men of Israel offer sacrifice, and Moses alone is the high-priest. Aaron, however, seems to be regarded as ancestor of one set of priests, those at the Hill of Phinehas, and perhaps of those at Bethel. In a later portion it is he who yields to the demand for an idol, and fashions the golden calf — an evident genealogy of Baal-worship, accredited to the ancestor of rival priests. In the Yahvistic portions he is Moses' older brother, but is brought upon the stage only to be ignored: Pharaoh sends for him and Moses to take away the plagues (Ex. vii.), but he has no independent power and is merely Moses' agent in performing miracles, bringing on plagues, etc. The supererogatory nature of his functions makes it probable that his rôle is introduced by the priestly redactor, under whose hands he becomes a mighty leader little inferior to Moses: he sometimes receives laws directly from Yahwé (Num. xviii.); he with Moses numbers the people; the Israelites rebel against him as well as Moses, though, when he criticises Moses, curiously his inciter Miriam is punished, not himself (Num. xii.); he and Moses jointly disobey Yahwé's command at Meribah; and he is punished by having his life close before entering Canaan. This magnifying connects itself clearly with the post-exilic books, where he is the ancestor of all legitimate priests, consecrated high-priest by Moses, and alone permitted to enter the Holy of Holies yearly: he represents the tribe of Levi, and even within it his descendants alone are rightful priests, and interlopers (see KORAH) are stricken dead by Yahwé. The pre-exilic prophets know nothing of this claim: Ezekiel traces the origin of the Jerusalem priesthood only to Zadok (q.v.). He belongs to the tribe of Joseph and its struggle to secure admission to the Jerusalem priesthood.

Aaron, Hill of, a lofty mountain range of Arabia Petræa, in the district of Sherah or Seir, 15 miles S.W. of Shobeck. On its highest pinnacle — called by the Arabs Nebi Haroun — is a small building supposed by the natives to inclose the tomb of Aaron; and it may be the Mount Hor of Num. xxxiii.

Aaron ben Asher, Jewish scholar: lived in Tiberias early in the 10th century. He completed one of the two existing recensions of the vowels and accents of the Hebrew Bible. His rival Ben Naftali also completed a similar work, but the readings of the former are usually preferred.

Aarsens, Frans Van, är'sens, Dutch diplomat: b. The Hague, 1572; d. 1641. From 26 on he represented the States-General at the court of France for many years, first as agent and then as ambassador; and Richelieu ranked him one of the three greatest politicians of his time. He also held embassies to Venice, Germany, and England. The judicial murder of John of Barneveld by Maurice of Orange in 1619 was greatly helped on by Aarsens, who has gained a tardy popular opprobrium for it through Motley's life of John.

Aasen, Ivar Andreas, â'sen, ē'var än'drā as, Norwegian philologist and poet: b. Örsten, 5 Aug. 1813. At first a botanist, he turned philologist and student of native dialects from patriotic enthusiasm: his great aim was to construct from their older elements a new national language ("Landsmaal"), as a substitute for Danish, in pursuance of which end he published several valuable philological works and set going the nationalistic movement called "maalstrœv." As a poet he produced 'Symra,' a collection of lyrics, and 'Ervingen,' a drama.

Aasvar, âs'-vär, Norwegian islands near the Arctic Circle, where the great Nordland herring are caught in December and January to the extent of sometimes 200,000 tons, and 10,000 men are employed, who live elsewhere the rest of the year.

Aasvogel, äs'fō-gel ("carrion-bird"), the South African vulture, of several different species.

Ab, the 11th month of the Hebrews' civil year and the 5th of their ecclesiastical (which begins with Nisan), has 30 days, and answers to the July moon, or part of our July and August. The 9th day was a great fast in memory

of the destruction of the first temple by Nebuchadrezzar, 586 B.C., and the second by Titus, 70 A.D.

Aba or **Abu Hanifah,** or **Hanfa,** ä'ba or ä'boo hä-nē'fa, or hän'fa, surnamed Alnooma: b. in the 80th and d. in the 150th year of the Hegira (701–771). He is the most celebrated doctor of the orthodox Mussulmans, and his sect is the most esteemed of the four which they severally follow.

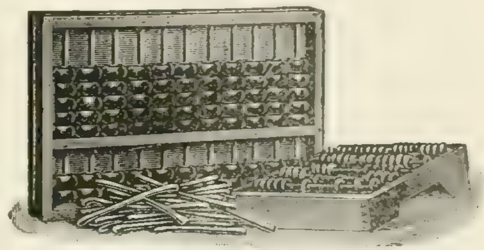
Aba, ä'ba, a mountain in Armenia, part of Mount Taurus, where the rivers Araxes and Euphrates have their rise.

Abab'deh, Abab'de, Abab'idek, or **Hab'ab,** a Hamitic people of E. Africa, descendants of the ancient Nubians, scattered throughout Nubia and between the Nile valley and the Red Sea, but chiefly from 23° N. lat. to the W. border of Lower Egypt. They are small-limbed, but well formed; very dark, but not negroid in features.

Abaco, ä'ba-kō (or **Lucaya**), **Great** and **Little,** two Bahama islands 150 m. W. of Florida. Great Abaco, the largest of the Bahamas, is about 80 m. long by 20 wide, with a lighthouse at its S.E. point, at a natural perforation of the rock known to seamen as "The Hole-in-the-Wall." Little Abaco, 28 m. long, lies W. of its N. point. Area of both, 879 sq. m.; pop. 2,400.

Abacus. In architecture, the flat stone forming the highest member of a column, next under the architrave and bearing its first weight. In the Tuscan, Doric, and Ionic orders, its four sides are arched inward, with generally a rose in the centre. In Gothic architecture it was variously employed, according to the architect's fancy.

Abacus (Greek ἄβαξ, from the Semitic אבק, *abq,* dust). In mathematics, a term applied to several forms of reckoning apparatus, and hence for some centuries to arithmetic itself. The primitive form seems to have been a board covered with fine dust, whence the generic name. Among the Hindus this was a wooden tablet covered with pipe clay, upon which was sprinkled purple sand, the numerals being written with a stylus. (Consult Taylor, in the preface to his translation of the 'Lilawati,' Bombay 1816, p. 6). That this form was used by the ancient Greeks is evident from Iamblichus, who asserts that Pythagoras taught geometry as well as arithmetic upon an abacus. Its use among the Romans of the classical period is also well attested. Another form of the abacus, having many modifications, is a board with beads sliding in grooves or on wires. Herodotus tells us that this instrument was used by the Egyptians and the Greeks, and we have evidence that the Romans also knew it, although preferring a form described below. It is at present widely used, appearing in the form of the *swanpan* in China, the *soroban* in Japan, and the *tschoty* in Russia, the latter being the same as the modern Arabian abacus. It is in this type of the abacus that prayer beads have their origin. The third form is a ruled table, upon which counters are placed, somewhat like checkers on a backgammon board, a game derived from this type of abacus. This was the favorite form among the Romans, whose numerals were not at all adapted to calculation, and it maintained its position throughout the Middle Ages and until the latter part of the 16th century. The Hindu-Arabic numerals (see NUMERALS) having then supplanted the Roman, such an aid to calculation was thought superfluous in western Europe. The counters used were called ψῆφοι by the Greeks, *calculi* (pebbles, whence *calculare* and our *calculate*) by the Romans, and in Cicero's time *aera* because brass discs were used. In mediæval times they were called *projectiles* because they were thrown upon the table, whence our expression to "cast an account," and Shakespeare's "counter caster." The early French



translated this as *gettons, gectoirs,* and *jetons,* whence our obsolete English *jettons* and the modern French *jeton,* meaning a medal, and also a counter for games. The Germans translated the late Latin *denarii supputarii* (calculating pennies) as *Rechenpfennige,* the early printed books distinguishing between reckoning on the line (that is, on the ruled table) and with the pen. The Court of the Exchequer (q.v.) derives its name from this form of the abacus, about which the judges of the fiscal court sat. (Hall, 'The Antiquities and Curiosities of the Exchequer,' London 1891; Henderson, 'Select Historical Documents of the Middle Ages,' London 1892, p. 20.) Another form of the abacus, possibly introduced by Gerbert before he became Pope Sylvester II. (q.v.), was arranged in columns and employed counters upon which the western Arab forms of the Hindu numerals (see NUMERALS) were written. The use of the term to designate an instrument of calculation led to its use for arithmetic itself, as in the 'Liber abaci' of Leonardo Fibonacci of Pisa (q.v.) and in the works of later writers.

Consult: Knott, 'The Abacus,' in the 'Transactions of the Asiatic Society of Japan,' Vol. XIV.; Bayley, in the 'Journal of the Royal Asiatic Society' (N. S.), Vol. XV.; Chasles, in the 'Comptes rendus,' t. 16, 1843, p. 1409; Woepcke, in the 'Journal asiatique,' 6 ser., t. 1. See FINGER NOTATION.

DAVID EUGENE SMITH,
Professor of Mathematics, Teachers College, Columbia University, New York.

Abad' ("abode"), a suffix meaning town or city, common in Hindu and Persian names: as Allahabad, city of God; Hyderabad, city of Hyder; Secunderabad, city of Alexander.

Abad'don, in the Old Testament and the rabbinical literature, Sheol, the underworld, or the place of the lost in it: in Revelation (ix. 11) the King of the Abyss, Greek APOLLYON.

Ab'adir, according to Augustine the chief god of the Carthaginians; according to Priscian, a stone which Saturn swallowed by contrivance of his wife Ops, believing it to be his new-born

son Jupiter, and hence worshipped with divine honors.

Abakansk', a mountain range in Siberia, extending from the upper Yenisei to the Tom R., parallel to the Altai Mts. Also a town founded by Peter the Great in 1707, near the Abakan River; now renamed Minusinsk (q.v.).

Ab'alo'ne (Sp., origin unknown). Any one of the several species of *Haliotis* (ear-shells or sea-ears) found along the California coast. The shell is a spiral so broadly flattened as to make an oval saucer, around the edge of which is a row of holes through which the tentacles pass when extended. The animal lives on rocks near the shore, feeding on seaweed; when frightened it withdraws entirely beneath its shell and clings with surprising force to the rock. The shell is lined with a bright mother-of-pearl much used in arts and crafts. The animal itself is used as food by the Chinese and Japanese; quantities of them are dried and exported from California to the Orient. The name "abalone" is local, but marine gastropods of the same family are abundant in all seas not too cold, outside the western Atlantic. See HALIOTIDÆ; SEA-EAR.

Abanah, ä-bä'nä, or **Amanah** (Gr. Chrysorrhoas, now Baradá, "The cold"), one of the two famous "rivers of Damascus" mentioned in the Scripture: rising in the heart of the Anti-Lebanon, it flows through a narrow gorge and spreads fan-wise through the Damascus oasis, irrigating the land and supplying the city, by the canals or "rivers," with its clear sparkling water, so greatly superior to the Jordan in beauty that Naaman's question is quite intelligible.

Abancay, ä-bän-kī', Peru, capital of dept. Apurimas, 65 m. W. of Cuzco, on the Abancay, an affluent of the upper Apurimac; in an East-Andean valley, the best sugar district in Peru, with large refineries and silver mines. Pop. (1889) 3,000.

Abandonment, the act of abandoning, giving up, or relinquishing.

In commerce it is the relinquishment of an interest or claim. Thus, in certain circumstances, a person who has insured property on board a ship may relinquish to the insurers a remnant of it saved from a wreck, as a preliminary to calling upon them to pay the full amount of the insurance effected.

The principle is also applicable in fire insurance, and often under stipulations in life policies in favor of creditors. The chief object of abandonment being to recover the whole value of the subject of the insurance, it is necessary only where the subject itself, or portions of it, or claims on account of it, survive the peril which caused the loss. At once upon receiving information of a loss the assured must elect whether to abandon, and not delay for the purpose of speculating on the state of the markets.

The English law is more restricted than the American, by not making the loss over half the value conclusive of the right to abandon, and by judging the right to abandon by the circumstances at the time of action brought, and not by the facts existing at the time of the abandonment. By commencing full repairs the right of abandonment is waived. An abandonment may be oral or in writing. When acted upon by another party, the effect of abandonment is to devest all the owner's rights.

Abano, Pietro di, ä'ba-nō, pēä'trō dē, known also as Petrus de Apono, one of the most celebrated physicians of the 13th century: b. in the Italian village from which he takes his name, in 1240 or 1250; d. 1316. He visited the East in order to acquire a thorough knowledge of Greek, and then completed his studies at the University of Paris. Returning to Italy he settled at Padua, where his reputation as a physician became so great that his rivals, envious of his fame, gave out that he was aided in his cures by evil spirits. It was known, too, that he practised astrology, and he was twice summoned before the Inquisition. On the first occasion he was acquitted, and he died before his second trial came to an end. Besides the work, 'Conciliator Differentiarum Philosophorum et Præcipue Medicorum' (Mantua, 1472), he wrote 'De Venenis eorumque Remediis' (1472), 'Geomantia,' 'Quæstiones de Febribus,' and other works.

Abano, Italy (Lat. "Fontes Aponi"), lies at the foot of the Vicentine Hills, in Lombardy. Its noted springs, much visited by invalids, were well known to the ancients, and are referred to by Martial and Claudian.

Aban'tes, an ancient Greek people originally from Thrace, who settled in Phocis, and built a town called Abæ. Their name implies an ancestor or leader Abas.

Abar'banel. See ABRABANEL.

Ab'arim ("the beyonds," sc. Jordan), the edge of the Moabite plateau overlooking the entire Jordan valley: a range of highlands forming its whole horizon, broken only by the valley mouths of the Yarmuk, the Zerka, and the Jabbok. Its highest elevation is Mount Nebo, whence Moses had his "Pisgah view" of Palestine (see PISGAH), and whence Jericho is plainly visible. Ancient altars, perhaps Amorite, were discovered here in 1881.

Ab'aris, the Hyperborean (fabled as from the Caucasus or thereabout), a legendary sage first mentioned by Pindar and Herodotus, 5th century B.C., but quite uncertain of date or existence. He had the prophetic gift, and a magic arrow of Apollo on which he rode through the air; cured by incantations, rid the world of a great plague, etc. The Neo-Platonists made him Pythagoras' companion.

Abascal, José Fernando, ä-bäs-cäl', hō-sā' fĕr-nän'dō, Spanish soldier and statesman: b. Oviedo, 1743; d. Madrid, 1821. Entering service in 1762, he rose to brigadier-general in the French Revolutionary wars; in 1796 became viceroy of Cuba and defended Havana against the English fleet; then was commander in New Galicia, and later viceroy of Peru, where he showed great ability and kindliness, and in recognition of his efforts to reconcile natives and Spanish was created Marqués de la Concordia. He defended Buenos Ayres from the English, and suppressed revolts in Lima and Cuzco; but having a turn of ill success was recalled in 1816.

Abasolo, Mariano, ä-bä-sō'lō, mä-rē-ä'-nō, Mexican patriot: b. in Guanajuato about 1780; d. Cadiz, 1819. Joining Hidalgo's (q.v.) Mexican revolution in 1810, he rose to major-general, and was noted for humanity to prisoners. After the final rout at the Calderon bridge, 17 Jan. 1811, he fled with his chief; with him was captured by the counter-revolutionists, tried, and

sentenced to life imprisonment in Spain, where he died.

Abatement. In law: (1) A removal or putting down, as of a nuisance. (2) A quashing; a judicial defeat; the rendering abortive by law, as when a writ is overthrown by some fatal exception taken to it in court. A plea designed to effect this result is called a plea in abatement. All dilatory pleas are considered pleas in abatement, in contradistinction to pleas in bar, which consider the merits of the claim. (3) Forcible entry of a stranger into an inheritance when the person seized of it dies, and before the heir or devisee can take possession. (4) The termination of an action in a court of law, or the suspension of proceedings in a suit in equity, in consequence of the occurrence of some event, as for example the death of one of the litigants. In contracts, a reduction made by the creditor in consideration of the prompt payment of a debt due by the debtor. In mercantile law, a deduction from duties imposed at the custom-house, on account of damages received by goods during importation or while in the custom-house.

A misnomer of plaintiff or defendant can be taken advantage of only by plea in abatement.

In heraldry, an abatement was formerly an addition to a coat-of-arms, indicative of disgrace or inferiority; now it is confined to the bend sinister, marking illegitimate descent.

Ab'atis, or **Abattis,** in military affairs, a defense made of felled trees. In sudden emergencies, the trees are merely laid lengthwise beside each other, with the branches pointed outward to prevent the approach of the enemy. When employed for the defense of a pass or entrance, the boughs of the trees are stripped of their leaves and pointed, the trunks are planted in the ground, and the branches interwoven with each other; and the abatis is laid in a depression in front of a trench, for protection from artillery fire.

Ab'atos, Egypt, an island in Lake Mœris, famous as the sepulchre of Osiris, and for producing the papyrus of which the ancients made their paper.

Abattoir (Fr.), ab-at-war, a slaughter-house; sometimes extended to include a great market of which the abattoir proper is only a part. The nuisance of blood, offal, etc., in crowded settlements, early forced ancient civilized governments to put the slaughter of the animals under restrictions. Our first definite information on this point is the system under the Roman empire: the slaughter-houses instead of being scattered about the streets were collected in one quarter, forming the public market, which in Nero's time was one of the most imposing structures in Rome. The system was introduced into Gaul, but the meat supply of Paris was in the hands of a clique of aristocratic families who balked all attempts at reform; and though as far back as 1567 Charles IX. had issued a decree on the subject, no improvement was made till Napoleon's time, when the nuisance was shocking,—slaughter-houses abutted on the principal thoroughfares, herds of footsore and lamenting beasts impeded traffic, the gutters ran with blood, offal poisoned the air, and the Seine was a sewer for it. A commission was appointed to rectify these conditions in 1810, and the five great abattoirs which still exist were formally opened 15 Sept. 1818. They have been the models of the world, and for many years had no rivals; indeed, for symmetry of arrangement they have never been surpassed. But of late the vast American establishments near Chicago, at Brighton, Mass., and other places, have carried speed, economy, and cleanliness to an ideal point, and American inventiveness has built up an incredible number of subsidiary industries and products, so that literally not a hair of an animal's body nor a drop of its blood is wasted: foods, medicines, chemicals, manures, building-materials, etc., produced from the refuse of the slaughter-houses are past numbering.

Abauzit, Firmin, ab-ō-zē, fēr-mañ, French scholar of Arabian blood and Protestant parents: b. Uzès, 1679; d. Geneva, 1767. He lost his father when only two; in 1685, on the Revocation, the authorities tried to tutor him for a Catholic, but his mother contrived his flight with an elder brother to the Cevennes, where after two years as fugitives they gained Geneva, and the mother escaped from imprisonment and joined them. He early acquired great proficiency in languages, physics, and theology; traveled to Holland and made acquaintance with Bayle and others, and to England, where Newton admired him greatly, corrected through him an error in his "Principia," and wrote to him, "You are well worthy to judge between Leibnitz and me." William III. wished him to settle in England, but he preferred to return to Geneva: assisted a society there in translating the New Testament into French, was offered but refused a chair in the University, but accepted a sinecure librarianship, and died very aged. He was of wonderful versatility and universality, seeming to have made everything a speciality; Rousseau, jealous of every one, yet eulogized him warmly; and Voltaire asked a flattering stranger who said he had come to see a genius, whether he had seen Abauzit. His heirs, through theological differences, destroyed his papers, so that little remains of his work; he wrote articles, however, for Rousseau's 'Dictionary of Music' and other works, and edited with valuable additions Spon's 'History of Geneva.' (Collected works, Geneva, 1770; London, 1773. Translations by Dr. Harwood, 1770, 1774. For personal information, see Senebier's 'Histoire Littéraire de Genève'; Harwood's 'Miscellanies'; Orme's 'Bibliotheca Biblica,' 1834.)

Abba, Giuseppe Cesare, joo-sep'ā chā-zä'-ra, Italian poet: b. 1838 at Cairo Montenotte. He took part in the expedition of Garibaldi into Sicily in 1860, which he celebrated in his poem 'Arrigo.' Among his other works are a tragedy, 'Spartaco,' a historical novel, and lyric poems.

Abba (same as papa, etc.), Aramaic form of Hebrew for "father." In the New Testament, used as an address to God; in the Talmud, a scholar's title of honor; also used as part of proper names; and at present the title of Syriac, Coptic, and Ethiopic bishops. See PAPA; POPE.

Abbadie, Antoine Thomson and **Arnaud Michel d',** dab-ad-ē, äñ-twan toñ-soñ (and ar-nō mē-shel, brothers and explorers: b. in Dublin, Ireland, 3 Jan. 1810 and 24 July 1815 respectively. In 1837–48 they explored Abyssinia and Upper Egypt, traveled up the White Nile, visited Darfur (regarded by the English

in these places as French emissaries), and made a remarkably large collection of Ethiopic and Amharic manuscripts. Among other works Antoine published 'Geodesy of Part of Upper Ethiopia' (1860–73) and 'Dictionary of the Amarin Language' (1881); and Arnaud, 'Twelve Years in Upper Ethiopia' (1868).

Abbadie, Jacques, ab-ad-ē, zhak, or **James,** eminent French-English divine: b. Nay, Bern, c. 1654–7; d. London, 1727. A poor boy, educated by friends, he took a degree of doctor in theology at Sedan at 17, was minister of a French Protestant church in Berlin some years, then in 1688 accompanied Marshal Schomberg to London for the second English Revolution, and became minister of the French church in the Savoy. He was strongly attached to William's cause, wrote an elaborate defense of it, and a history of the conspiracy of 1696 from materials furnished by the government; and William made him dean of Killaloe, Ireland. A very able man and eloquent preacher, Abbadie is best known by his religious treatises in French, several of them translated into other languages: the most important are that 'On the Truth of the Christian Religion,' with its sequel 'On the Divinity of Jesus Christ,' and 'The Art of Self-Knowledge.

Abbas (IBN ABD IL MUTTALIB, 'bn äbd il moo-ta'lib), uncle of Mohammed; at first hostile to him, but ultimately — after the defeat at Bed'r (see MOHAMMED) — the chief promoter of his religion. He was the founder of the Abbasside (q.v.) caliphate at Bagdad.

Abbas I., of Persia, "the Great," 7th shah of the Sufi dynasty: b. 1567, acceded 1585: d. 27 Jan. 1628. Sent to Khorasan as nominal governor in childhood, at 18 he was proclaimed shah by its nobles, smarting under the oppression of his father Mohammed Khodabendeh's officers; the father was soon driven from the throne. At this time the Turks had invaded the western Persian provinces, and the Uzbek Tartars occupied and ravaged Khorasan. Abbas first transferred his residence from Kasbin to Ispahan; he then by treaty confirmed to the Turks all their conquests, to gain time for chastising the Uzbeks, whom in 1597 he surprised and routed near Herat, and followed this by the conquest of Ghilan, Mazanderan, much of Tartary, and nearly all Afghanistan. He then declared war against the Turks; and in 1605, with 60,000 men, annihilated their army of nearly double the number at Basra, Bussorah), recovering all the lost provinces, and not only securing complete immunity from Turkish aggression for the rest of his life, but extending his empire beyond the Euphrates. In 1611 he dictated to Achmet I. a treaty which gave Persia Shirwan and Kurdistan. In 1618 he routed the united Turkish and Tartar armies near Sultanieh, securing more territory; and on the Turks renewing the war in 1623 he captured Bagdad after a year's siege. The same year he took Ormuz from the Portuguese; and when he died his dominions reached from the Tigris to the Indus. His internal administration was no less firm and beneficial. He encouraged commerce, built highways, repressed violence, and left the country flourishing as it never has since. He was favorable to foreigners, and two Englishmen, Sir Anthony and Sir Robert Shirley, had much influence over him. He was like Herod in every respect: a jealous and cruel tyrant to his family,— he slew his eldest son and blinded his other children,— his country alone felt his good side.

Abbas-Mirza, a Persian prince and warrior, favorite son of the shah Feth-Ali: b. 1783; d. 1833. He was early convinced of the advantages of Western civilization, and with the help of European officers he first of all applied himself to the reform of the army. He led the Persian armies with great bravery, but with little success, in the war with Russia ended by the peace of Gulistan, when Persia lost her remaining Caucasus districts and ceded to Russia the sovereignty of the Caspian; and in that of 1826–8, ended by the peace of Turkmanchai, when she lost most of Persian Armenia. In 1829 he visited St. Petersburg, to ward off punishment for the murder of the Russian ambassador in a riot at Teheran; and was sent back to Persia loaded with presents. His eldest son acceded to the throne in 1834.

Abbas Pasha I., viceroy of Egypt, grandson of the famous Mehemet Ali: b. 1813; d. 13 July 1854. Early initiated into public life, in 1841 he took an active part in his grandfather's Syrian war; in 1848 the death of his uncle Ibrahim Pasha called him to the viceregal throne at Cairo. During his brief reign he did much to undo the progress made under Mehemet Ali: he dismissed all Europeans and fought Western ideas energetically. At the outbreak of the Crimean war he placed 15,000 men and his fleet at the Sultan's disposal; but was shortly after found dead, not without suspicion of foul play.

Abbas Pasha II., Hilmi, hēl'mē, khedive of Egypt, eldest son of the khedive Tewfik: b. 1874: studied at Vienna: on his father's death in 1892 became khedive. He won popularity by reducing the taxes, and tried to throw off the English influence. In 1893 he dismissed four of his ministers, but Lord Cromer interfered and he agreed to follow England's recommendations in all important matters. See also NUBAR PASHA.

Abbassides, abăs'sīdz, **The,** 750–1517, caliphs at Bagdad and later in Egypt; nominal sovereigns of all Islam, but losing Spain at the outset, and never practically obeyed in Africa outside Egypt; the most famous dynasty of Saracen sovereigns. They took their name from Abbas (q.v.), the uncle of Mohammed. This descent had given the family great influence by a century after the Prophet's death; and Ibrahim, fourth in descent from Abbas, had gained several victories over the Ommiads (q.v.), supported by the province of Khorasan, when the Ommiad caliph Merwan defeated and put him to death in 747. His brother Abu 'l-Abbas, whom he had named his heir, assumed the title of caliph, crushed the Ommiad dynasty in a decisive battle near the Zab (750) and acceded to their position. Its members and relatives were nearly all tolled into one spot and exterminated, earning for Abu 'l-Abbas the nickname of As-Saffah, "the butcher"; but one of them, Abd-er-Rahman (q.v.), escaped, and after picturesque adventures set up an independent emirate in Spain, which toward two centuries later took the title of caliphate. On Abu 'l-Abbas' death, his successor Al-Mansur r moved the seat of royalty to Bagdad, and w successes against Turkomans and Greeks in Asia Minor; but by this time the warlike impulse had

begun to decay, and the love of luxury and its literary and artistic attendants to come to the front. Means were found of evading the strictness of Mohammedan rules; and no courts of any age or country were gayer or more splendid than those of the great Harun al-Rashid, Charlemagne's contemporary (786–809), and Al-Mamun (813–833). The splendor of their palaces, their decorations, their equipages, and the seemingly exhaustless treasures they possessed, gave them a world-wide celebrity — especially in contrast with the poverty-stricken barrenness and barbarism of most Christian sovereigns at that period — which is vivid even yet in literature and popular memory: Harun is the chief princely figure of the 'Arabian Nights,' and Bagdad the center of all picturesque and varied enjoyment. Al-Mamun is still more honorably remembered as the patron of arts and literature. What lay underneath this external gorgeousness — the corruption, the furies of jealousy and bloodshed, and the barbarous oppression of the many — is outside a notice like this. But external decay soon began to witness internal rottenness. The Ashlabites, Edrisites, etc., carved out independent sovereignties in Africa; the Taherites in 820 set up a separate power in Khorasan, even under the great Al-Mamun. The Greeks, under the new life of the Byzantine empire brought in by Leo the Isaurian (q.v.), pushed them back in Asia Minor; and Al-Mamun's last years were contemporary with the philosopher, soldier, and statesman, the all-accomplished Emperor Theophilus. But the final stroke came from barbarians. The caliph Motassem (833–842), who had fought both Theophilus and the hordes of Turkestan successfully, distrusting his subjects, formed body-guards out of his Turkish prisoners. They soon became what the Roman prætorians were — masters of the empire. Motassem's son Motawakkel was assassinated by them in his palace (861) and the succeeding caliphs were their puppets; and in 936 the caliph Radhi (934–41) was forced to give up the command of the army and other powers to his general and mayor of the palace, Mohammed ben Rayek. The provinces one after another threw off allegiance; the caliph held only Bagdad and its neighborhood; and at last Hulagu, prince of the Mongols, fired Bagdad and slew the reigning caliph Motassem in 1258. The Abbassides retained a nominal caliphate in Egypt under the ægis of the Mamelukes, and never gave up the claim or the hope of their old position and seat; but in 1517 the Turkish Sultan Selim I., the conqueror of Egypt, bore the last of them, Motawakkel III., a prisoner to Constantinople, finally allowing him to return to Egypt, where he died a Turkish pensioner in 1538. (Muir's 'Caliphate' for the best English account; the monumental treasure-house of information for scholars is Weil's great 'Geschichte der Chalifen,' 1846–62.)

Abbate, āb-ä'te, or **Abati,** ä-bä'tē, **Nicolo,** nē'kō-lō, Italian painter, follower of Raphael and Corregio: b. 1512 at Modena, where his earlier works are exhibited; d. 1571 at Fontainebleau — his frescoes in which palace are his best-known productions. His finest piece, however, is regarded as 'The Adoration of the Shepherds,' at Bologna, where his later work re[illegible]stly exists. He has another in the Dresden gallery.

Abbe, Cleveland, American meteorologist: b. New York city, 3 Dec. 1838. Graduated 1857 at the Free Academy (now College of the City of New York); studied astronomy at Ann Arbor with Brünnow and at Cambridge with Gould (1858–64); resided at Pulkova observatory, Russia, 1864–6; director Cincinnati Observatory 1868–73, where he began the system of co-ordinated daily weather forecasts which led to the United States establishing the same system and in 1870 calling Prof. Abbe to Washington to direct it, making him professor of meteorology in the Weather Bureau. May 1879 he initiated the movement toward standard time (q.v.) and hour meridians. January 1873 he started the 'Monthly Weather Review,' of which he has remained editor. He is professor of meteorology in Columbia University, Washington, lecturer on the same at Johns Hopkins, etc. Among his publications are a work on 'Meteorological Apparatus and Methods' (1887); 'Studies for Methods in Storm and Weather Predictions (1889); 'Mechanics of the Earth's Atmosphere' (1891), 'Solar Spots and Terrestrial Temperature,' and 'Atmospheric Radiation.'

Ab'be, Ernst, German physicist: b. Eisenach, 1840; d. Jena, 1905. Studied at Jena and Gottingen; became assistant at the latter's observatory, and lecturer before the Frankfort-on-the-Main Physical Society; 1863–70 lecturer at Jena, and 1870 professor there; 1878 director of its observatories; in 1891 he resigned professorship. He became distinguished for his work in perfecting optical instruments, especially photograph and microscope lenses, having for a long time been connected with the highly reputed firm of Carl Zeiss in Jena. He invented the Abbe refractometer. He wrote a work in German on the 'Refracting and Dispersing Power of Solid and Fluid Bodies.'

Abbe, ab-ā, originally the French name for an abbot, but later used in the general sense of a priest or clergyman. By a concordat between Pope Leo X. and Francis I. in 1516, the French king had the right to nominate upward of 200 *abbés commendataires*, who drew a third of the revenues of the monasteries without having any duty to perform. They were not necessarily clergy, but were expected to take orders unless exempted by a dispensation. The hope of obtaining one of those sinecures led multitudes of young men, many of them of noble birth, to enter the clerical career, which however seldom went further than taking the inferior orders; and it became customary to call such aspirant abbés, jocularly, Abbés of St. Hope. They formed a considerable and influential class in society; and an abbé, distinguished by a short violet-colored robe, was often found as chaplain or tutor in noble households, or engaged in literary work. This class of nominal clergy disappeared at the Revolution. In Italy they are called *abbate*.

Abbess, the female superior of some convents of nuns, corresponding to the abbot over monks. She was elected from the monastery by secret votes, inducted by a bishop's consecration, and held office three years or even for life unless deprived for misconduct. The Council of Trent fixed the required age at 40, with 8 years of professed membership in the monastery. She could discipline and even expel the nuns, subject to the bishop; but, being a female, could

exercise only certain functions, such as giving religious counsel and administering the rule, but no spiritual jurisdiction, as ordaining, conferring the veil, or excommunicating.

Abbeville, France, ab-vēl ("abbey-town," of St. Riquier's), capital of Abbeville arrondissement, dept. Somme; on both banks of the Somme and an island in it, 12 m. from its mouth and head of navigation (at high tide vessels of 150 to 200 tons can reach it) connected by canals with Amiens (25 m. distant), Lille, Paris, and Belgium; on the Northern Ry. It is an old, narrow-streeted, picturesque town, with strong fortifications on Vauban's system; has a wonderfully fine church of the flamboyant order, St. Wolfran's, begun under Louis XII. (1462–1515), a very interesting city hall built in 1209, and a library of 1690 now containing 45,000 volumes. It manufactures jewelry, soaps, glassware, and various fabrics, as velvets, cottons, linens, etc. But its chief interest to the foreign world is for the relics and implements of primitive man (the cave-dweller) and the fossils of extinct animals found there. Pop. (1896) 17,781.

Abbeville, S. C., county seat of Abbeville co.; on the Southern and Seaboard A. L. R.R.'s; 106 m. W. of Columbia. It is in a rich cotton-growing region; is noted for its fine climate, which makes it a popular resort for Northern invalids, and has a national bank, excellent public schools, several large manufactories connected with the cotton industry, flour and feed mills, brick-yards, etc. Property valuation over $500,000; bonded debt less than $55,000. There are several periodicals. Pop. (1890) 1,696; (1900) 3,766.

Abbeville Treaties. (1) A treaty in 1259 between Louis IX. of France ("St. Louis") and Henry III. of England, to settle definitely the territorial rights of the two crowns, Louis fearing that his title to some possessions was liable to dispute, and having sought a settlement for many years. It was negotiated at Paris with Simon de Montfort, Earl of Leicester, and signed by the two kings at Abbeville during Henry's visit to France, 1259–60, but dated back to 20 May 1259. Henry resigned all title to Normandy, Maine, Anjou, Touraine, and North Saintonge; Louis turned over Périgord, Limousin, South Saintonge, and some districts south of the Loire, to be held by Henry in fief,— a surrender which so enraged the inhabitants that they refused to celebrate Louis' birthday. Henry resigned the titles of Duke of Normandy and Count of Anjou, and agreed to do homage at Paris for those of Duke of Guienne and peer of France. (2) Between Henry VIII. and Francis I. in 1527, Wolsey representing England.

Abbey, Edwin Austin, American artist: b. Philadelphia, 3 April 1852; studied at the Pennsylvania Academy of Fine Arts; lived in New York and drew illustrations of a high order for periodicals, also painting water-colors, till 1883, when he removed to England. His two most individual qualities have been his love for English country life and scenery and for the old English poets and dramatists, both of which have resulted in notable illustrations (as of Shakespeare, Goldsmith, etc.) and paintings; and his ability as a colorist, though much of his work has been done without color. He has also deep intellectual and spiritual qualities; and all these faculties and tastes together combine in the famous panels of the 'Search for the Holy Grail' on the upper walls of the delivery room at the Boston Public Library. He was elected member of the Royal Academy July 1898; was one of the American jurors on paintings in the Paris Exposition of 1900; and was commissioned by Edward VII. to paint the coronation scene in Westminster Abbey. (See Radcliffe's 'Schools and Masters of Painting,' 1898; Müther's History of Modern Painting,' 1896.)

Abbey, Henry, poet and journalist: b. Rondout, N. Y., 11 July 1842. He has published several collections of pleasing verse: (May Dreams' (1862); 'Ralph, and Other Poems' (1866); 'Ballads of Good Deeds' (1872); 'Collected Works' (1885; 3d ed. 1895); 'Phaeton' (1901).

Abbey, Henry Eugene, American operatic manager: b. Akron, O., 27 June 1846; d. 1896. He was engaged for several years in theatrical, and from 1883 in operatic management, producing Italian and German operas with the most distinguished singers of the day.

Abbey, a monastery or religious community of the highest class, governed by an abbot, assisted generally by a prior, sub-prior, and other subordinate functionaries; or, in the case of a female community, superintended by an abbess. A priory differed from an abbey only in being on a smaller scale, and governed by a superior named a prior. Abbeys or monasteries first rose in the East. Among the most famous abbeys on the European continent were those of Clugny, Clairvaux, and Citeaux in France; of St. Galle in Switzerland, and of Fulda in Germany; in England, those of Westminster, St. Mary's of York, Fountains, Kirkstall, Tintern, Rievaulx, Netley, Paisley, and Arbroath. The English abbeys were wholly abolished by Henry VIII. at the Reformation. Abbeys were usually strongly built, with walls which served as a defense against enemies and within which were large buildings in which the occupants carried on the work to which they had been assigned. See Abbot; Monastery.

Abbitib'bi, a river, a lake, and a former important trading-post of the Hudson Bay Company in the Northwest Territories of Canada. The river is the outlet of the lake, about 49° N. lat., and flows into James Bay; the post is on the shore of the lake.

Abbo of Fleury, flė-rē, French theologian; b. near Orléans about 945; d. 1004. He studied at Rheims and Paris; acquiring great repute as a scholar and scientist (of the time), Oswald, Archbishop of York, induced him to teach for two years in the abbey of Ramsey and aid in restoring the monastic system; on his return to France he became abbot of Fleury and built up a thriving school there; was sent by Robert II. (son of Hugh Capet) on two missions to Rome, 986 and 996, and each time succeeded in warding off a papal interdict. Later, while trying to reform the discipline of the priory of La Réole, Gascony, he was killed. He wrote lives of the early popes down to Gregory I. (Life by his pupil Aimoin, in Latin, 'Vita Abbonis abbatis Floriacensis.')

Abbot, Ezra, American Biblical scholar: b. Jackson, Me., 28 April 1819; d. 21 March 1884.

He studied at Phillips Exeter Academy, graduated at Bowdoin 1840, and after teaching in Maine and Cambridge, Mass., became in 1856 assistant librarian of Harvard. In 1872 he received a D.D. from Harvard, though a layman, and thence till death was professor of New Testament criticism and interpretation in the Cambridge Divinity School. His wide reading and wonderful verbal memory made him one of the foremost of textual critics and bibliographers; his mastery of the Greek New Testament text placed him beside the leading scholars of the world; and on the American New Testament Revision Committee, 1871-81, he was a chief agent in putting its work on an even level of authority with the English, in minute accuracy of scholarship as well as broad, acute judgment. Indifferent to fame, he gave his best work to collaborations or private assistance mostly unacknowledged and unrealized except by scholars. His most important individual book was on the 'Authorship of the Fourth Gospel' (1880), in which he announced the important discovery of Tatian's 'Diatessaron.' Of his other critical work, besides the great Revision, his half of the prolegomena to Tischendorf's Greek New Testament (1884-94), his additions to Mitchell's 'Critical Handbook of the New Testament' (1880), and his revision of Schaff's 'Companion to the New Testament' (1883), should be mentioned. As a bibliographer, his greatest fame was for the curious and exhaustive catalogue of relevant books he furnished for Alger's 'Critical History of a Future Life' (1864), and his notes to Smith's 'Bible Dictionary' (Am. ed. 1867-70). He also wrote many papers for periodicals.

Abbot, Francis Ellingwood, American religious radical: b. Boston, 1836; graduated at Harvard 1859, and Meadville (Pa.) Theological School 1863. A Unitarian minister 1863-8, he started in 1870 *The Index,* an ultra-radical weekly devoted to religious and philosophical topics; and wrote 'Scientific Theism' (1886), and 'The Way Out of Agnosticism' (1890), besides notable magazine articles.

Abbot, George, Archbishop of Canterbury: b. Guildford, Surrey, 19 Oct. 1562; d. 5 Aug. 1633. A cloth-worker's son, he studied at Balliol, Oxford, was chosen Master of University College 1597, and three times was vice-chancellor of Oxford. Dr. Abbot's name was second on the list of eight divines ordered in 1604 to prepare the present (King James) version of the Bible. In 1608 he went to Scotland with the Earl of Dunbar to arrange for a union of the English and Scotch churches. James took a great fancy to him, and, though Abbot had never held a parish, made him bishop of Lichfield and Coventry in 1609, transferred him to the see of London a month later, and less than a year afterward appointed him Archbishop of Canterbury. Flattery of the king is accredited as the cause of this astonishing rapidity of preferment; but once in his seat, at least, Abbot felt no need of such tactics. He opposed the scandalous divorce suit of Lady Frances Howard against the Earl of Essex, though the court favored and carried it. In 1618 he forbade the reading, in the Croydon church where he was, of the king's declaration permitting games and sports on Sunday, which the Puritans (to whom Abbot belonged) regarded as a permit to break the Sabbath, and the order to read it as a command to commit blasphemy. He promoted the marriage between the Princess Elizabeth and the Protestant Elector Palatine, and opposed the disastrous Spanish-marriage project of Prince Charles, and thereby won Charles', Laud's, and Buckingham's hatred. The king, however, remained his friend. In 1622 he accidentally killed a keeper while deer-hunting, and his enemies tried to have him disqualified for the involuntary manslaughter. The king made light of the matter, but had to refer it to a commission, which decided in his favor, and he was formally absolved and reappointed. He attended James in his last sickness, and crowned Charles. The latter, on Abbot's refusing to license a fanatical divine-right sermon, deprived him of his functions and put them in commission; but, having to summon a parliament shortly after, was afraid of the effect and restored him. From that time he lived in retirement, leaving Laud in complete ascendancy. He wrote many works now forgotten, though one on the prophet Jonah was reprinted in 1845. A geography passed through numerous editions.

Abbot, Henry Larcom, American military engineer: b. Beverly, Mass., 13 Aug. 1831; graduated at West Point 1854; entered the engineer corps. He took part in the survey for a Pacific railroad and of the Mississippi River delta. He served through the Civil War as engineer and artillerist, was wounded at Bull Run, and commanded the siege artillery before Richmond, an account of which he published in 1867. He became colonel and chief of engineers, and was brevetted brigadier-general U. S. Vols., and major-general U. S. Army. He long commanded the engineers' garrison at Willett's Point, N. Y., established an engineers' school, worked out and laid down the submarine defenses of New York harbor, and accomplished much in the improvement of mortar batteries and engineering equipment, etc.; was a member of the Gun Foundry Board and the Board of Fortifications and Defense, of that for the protection of the Mississippi basin, of that on the proposed canal from Pittsburg to Lake Erie, and of the technicay Committee of the new Panama Canal Co. He drew the plans for the harbor at Manitowoc, Wis. He was retired in 1895. He is a member of many scientific societies, including the National Academy of Sciences; and has written, besides many reports of boards and committees and the work above cited, a volume on submarine mines for harbor defense (1881), and, in collaboration, 'Physics and Hydraulics of the Mississippi.'

Abbot, Joseph Hale, American educator: b. Wilton, N. H., 26 Sept. 1802; d. 7 April 1873. Graduated at Bowdoin 1822, tutor there 1825-7; professor of mathematics Phillips Exeter Academy 1827-33; then taught a ladies' school in Boston; subsequently was principal of the Beverly, Mass., high school. He was for some years recording secretary of the American Academy of Arts and Sciences, and published valuable scientific papers in its 'Transactions,' besides writing on pneumatic and hydraulic problems, in which he made ingenious investigations. He was associate editor of Worcester's Dictionary.

Abbot, Samuel, American philanthropist: b. Andover, Mass., 25 Feb. 1732; d. 12 April 1812. He became a wealthy Boston merchant and gave $20,000 in 1807 toward founding Andover Seminary, with $100,000 more by will.

Abbot ("father"), originally the head and ruler of a community of monks; in the Greek Church *hegumenos*, «leader,» or archimandrite, «ruler of the fold,» though the latter is oftener an abbot-general with *hegumenoi* under him. Among the Dominicans the head of a convent was called *præpositus*, a «provost,» or *prior;* among the Franciscans *custos*, «guardian»; among the Camaldules *major*. The term «abbot» originated in the East, and was first applied to any monk noted for piety, but at length restricted to the superior. The first abbots were laymen like the rest of the monks in general; the lowest clergy took precedence of them, and for sacraments they had to attend the nearest church: but the extreme inconvenience or even impossibility of this when the monastery was in a desert or far from a town forced the ordination of the abbots. Abbots could attend councils, and the second Council of Nice, 787, allowed them to ordain monks to the inferior orders; and ultimately nearly all monks were ordained to some grade of the ministry. To this elevation was added that of allowing pluralities of abbacies, originally forbidden, and even in the 6th century allowed only in special cases; but it increased till early in the 10th century one German prelate had twelve abbeys under him, corresponding to the archimandrites of the East. Thus, and by the increase of numbers and corporate wealth in the great abbeys, the abbots themselves became prelates of vast power. Still another cause developed this,— the exemption of abbeys from control of the bishops. They were originally all subject to episcopal jurisdiction, and in the West generally continued so till the 11th century; this is expressly ordered in Justinian's code. The exactions of the bishops, however, rendered the exemption increasingly frequent; beginning in 456 the practice grew, and was much helped forward by Gregory the Great, who relieved many abbots from episcopal control and made them responsible directly to the Pope. By the 12th century this had become an evil of the first order in ecclesiastical government, the bishop usually having no authority whatever over the chief centres of religious and often secular power in his diocese; and one abbot, of Fulda in Germany, claimed precedence over the Archbishop of Cologne. Next came an encroachment on the functions of the bishops: from conferring the tonsure and the office of reader they came to be equally associated with the bishops in consecrations; and while originally the bishop chose the abbot from the monks of the house, and then the right of election was transferred to the monks, the abbots came sometimes to choose their own successors. This, however, was stopped in some countries by a counter-process; the popes in Italy and the kings in France assuming to themselves the right of appointment.

Otherwhere the choice was by secret election of and from the monks of the house, unless it furnished no fit candidate, when choice might be made from another monastery of one well instructed himself and competent to instruct others, of legitimate birth and at least 25 years old. His election was for life. His power was absolute except as restricted by the canons of the Church. His exaction of deference in the routine of life was royal: all rose and bowed when he entered the church or chapter, his letters and orders were received kneeling, and no monk could sit in his presence or leave it without permission. They had immense political power, and were on equal terms of intimacy with the greatest in the realm. Many of the abbots were an honor to their countries, and their schools were seminaries of learning and virtue.

In time the title was improperly conferred on others who had no connection with monastic life, or sometimes even with the Church,— on the principal of a body of parochial clergy or the king's chaplain, and the chief magistrate of Genoa was called «Abbot of the People.» Lay abbots, so called, originated in temporarily handing over the revenues of an abbey to some noble, or even the king, for a great public exigency, the noble being titular abbot, but enough of the revenues being reserved from sequestration to support the house. Once in lay hands they usually remained there, and most of the Frankish and Burgundian sovereigns and chief nobles in the 9th and 10th centuries were titular abbots of great monasteries, whose revenues they applied to their own uses. This often happened from the monastery's voluntarily placing itself under the «commendation» of some noble for protection; and there were sometimes two lines of abbots,— one lay, taking the major part of the income without service, the other clerical, doing the work. This was mostly reformed during the latter part of the 10th century.

In convent cathedrals, where the bishop filled the place of the abbot, the superior's duties were performed by a prior. In other convents the prior was the vice-abbot. The superiors of cells, or small monastic establishments dependent on the larger ones, were also called priors; they were appointed by the abbot and held office at his pleasure. (H. J. Feazey's 'Monasticism'; Montalembert's 'Monks of the West,' ed. 1896, Vol. I.; Bingham's 'Origines'; Martene's 'Rites of the Ancient Monasteries.')

Abbot, The, by Sir Walter Scott. A sequel to 'The Monastery,' but dealing with more stirring situations. The time of the action is 1567–68. While the action goes on partly at Avenel Castle, and Halbert Glendinning of 'The Monastery,' as well as his brother Edward (now an abbot) figure prominently in the story, the reader finds that he has exchanged the humble events of the little border vale by Melrose for thrilling and romantic adventures at Lochleven Castle on its island in the lake, north of Edinburgh, where Mary Queen of Scots is imprisoned. The chief interest centres around the unfortunate queen. The framework of the tale it is claimed is historically true.

Abbotsford, a fording-place of the Tweed near its confluence with the Yarrow; the name given by Sir Walter Scott to his property there bought in 1811, in memory of its use by the monks of Melrose Abbey, it being at the time known as the Clarty [Filthy] Hole. The site is

a low hillside on the southern bank, overlooked by the Selkirks. At first only a villa, now the west wing of the pile, he was seized with the idea of founding a great feudal family of the old Scotch pattern, with this for a baronial seat; and gradually added other sections, copying old Scotch mansions or ruins, or special features of them, making an irregular, rambling, picturesque abode, «a romance in stone and lime.» It now belongs to the Hope-Scotts, descendants of Scott's daughter and Lockhart.

Abbott, Alexander Crever, American hygienist: b. Baltimore, Md., 26 Feb. 1860. He was educated at Johns Hopkins University and at the universities of Maryland, Munich, and Berlin. He is a fellow of the College of Physicians in Philadelphia, and a member of numerous scientific societies; in 1900 was professor of hygiene and director of the laboratory of hygiene in the University of Pennsylvania. His publications include ‹The Principles of Bacteriology,› and numerous papers on bacteriology and hygiene.

Abbott, Austin, LL.D., American law-writer, son of Jacob: b. Boston, 18 Dec. 1831; d. 1896. He was graduated at the University of the City of New York in 1851, and entered the practice of law; collaborated with his brother Benjamin in valuable legal compilations, digests, text-books, etc.; was an able law lecturer, and dean of his alma mater's law school 1891-6. He was counsel for Theodore Tilton in the Beecher trial. With his brothers Benjamin and Lyman he wrote two novels, ‹Cone Cut Corners› (1855) and ‹Matthew Caraby› (1858).

Abbott, Benjamin, revivalist: b. Long Island 1732; d. Salem, N. J., 14 Aug. 1796. A hatter's and then a farmer's apprentice, somewhat dissipated but a kind husband and father and a church-goer (whence his accounts of the pit from which he was rescued are probably dialectic), he was roused to intense conviction of sin at 33 by an itinerant Methodist preacher, joined that Church with his children and his Presbyterian wife, and became one of the most remarkable revivalists of the time, producing wonderful conversions of the most hardened, and often sending hearers into convulsions. In the Revolution the Methodists were suspected of disloyalty, and more than once he was near being mobbed; but he always preached down his assailants, once turning from their purpose a gang of a hundred soldiers. Serving for 16 years as a local preacher, from 1789 he went on various circuits, and in 1793 was made an elder and sent to Maryland. He carried on his duties till death despite much enfeeblement; and his career has been one of the most stirring themes for exhortation in the Church.

Abbott, Benjamin Vaughan, American lawyer, eldest son of Jacob: b. 4 June 1830; d. 1890. He was graduated at the University of the City of New York in 1850, and practised law with his brothers Austin and Lyman. He compiled nearly 100 volumes of legal digests and reports. He drew up in 1865, as secretary of the New York Code Commission, the penal code which is the basis of the present one. In 1870 President Grant appointed him one of three commissioners to revise the United States statutes, which occupied three years, and compressed 16 volumes into one large octavo; thence till 1879 he was occupied on a great revision of the ‹United States Digest.› Among his lesser works are ‹Judge and Jury› (1880), collected contributions to periodicals; a Chautauqua book, ‹The Traveling Law School›; and ‹Famous Trials› (1880).

Abbott, Charles Conrad, author and naturalist: b. Trenton, N. J., 4 June 1843. He received an academical education, and took the degree of M.D. at the University of Pennsylvania in 1865. His life is devoted wholly to scientific and literary pursuits. He is corresponding member Boston Society of Natural History; member American Philosophical Society of Philadelphia; Fellow Royal Society of Antiquaries of North, Copenhagen; Assistant, Peabody Museum of American Archæology and Ethnology, Cambridge, Mass., 1876-89. Author: ‹Primitive Industry› (1881); ‹Naturalist Rambles about Home› (1884); ‹Upland and Meadow› (1886); ‹Waste-land Wanderings› (1887); ‹Days Out of Doors› (1889); ‹Outings at Odd Times› (1890); ‹Recent Rambles› (1892); ‹Travels in a Tree-top› (1894); ‹The Birds About Us› (1894); ‹Notes of the Night› (1895); ‹A Colonial Wooing› (novel, 1895); ‹Birdland Echoes› (1896); ‹When the Century was New› (novel, 1897); ‹The Hermit of Nottingham› (novel, 1897); ‹The Freedom of the Fields› (1898); ‹Clear Skies and Cloudy› (1899); ‹In Nature's Realm› (1900); Report on Indian Stone Implements, in ‹American Naturalist› (1872), revised and enlarged as ‹Stone Age in New Jersey,› in Smithsonian Annual Report of 1876. In 1876 he announced the discovery, since confirmed by other archæologists, of traces of man in the Delaware River valley, dating from at least the close of the glacial period.

Abbott, Edward, D.D., American clergyman, son of Jacob: b. Farmington, Me., 15 July 1841. He was graduated at the University of the City of New York 1860, and at Andover Theological Seminary 1862; in 1863 was with the United States Sanitary Commission at Washington and in the field. The same year he was ordained Congregational clergyman, and 1865-9 was pastor of the Pilgrim Church, Cambridge, Mass.; in 1879 he was ordained Episcopal priest and ever since has been rector of St. James', Cambridge; in 1889 he was elected missionary bishop of Japan, but declined. He was associate editor of the ‹Congregationalist› 1869-78, and editor of the ‹Literary World› 1878-88, and again from 1895. Among his works are ‹Conversations of Jesus› (1875); ‹Paragraph History of the United States› (1875); ‹Paragraph History of the American Revolution› (1876); ‹Long Look Series,› juvenile (1877-80); memorial of his father (1882); and ‹Phillips Brooks› (1900).

Abbott, Edwin Abbott, English theologian and Shakespearean scholar: b. London, 20 Dec. 1838; graduated at St. John's College, Cambridge; senior classic and Chancellor's medalist (1861). He was master at King Edward's School, Birmingham, 1862-4, and at Clifton College; and head-master of the City of London School, 1865-89, raising it to a foremost rank in England. In the latter year he retired. He has been select preacher at Cambridge and Oxford. His works include the well-known ‹Shake-

spearean Grammar› (1869, enlarged 1870), still a classic; ‹Bacon and Essex› (1877); ‹Philochristus› (1878), and ‹Onesimus› (1882), two anonymous romances of the first age of the Church; ‹Francis Bacon› (1885); ‹Anglican Career of Cardinal Newman› (1892); ‹St. Thomas of Canterbury› (1898); volumes of sermons, and other religious works.

Abbott, Emma (Wetherell), one of the foremost of American dramatic sopranos: b. Chicago, Ill., December, 1849; d. Salt Lake City, 5 Jan. 1891. Beginning in Plymouth Church choir, Brooklyn, N. Y., she studied abroad with Sangiovanni at Milan and with Delled Sedie, Wartel, and James at Paris; then joined Mapleson's troupe, made her début at Covent Garden, London, toured three years in Great Britain, and returning to the United States spent her remaining years there, the later ones with the Emma Abbott English Opera Company. In 1878 she married E. J. Wetherell of New York.

Abbott, Frank Frost, American Latinist: b. Redding, Conn., 27 March 1860; graduated at Yale 1882; Latin tutor at Yale 1885–91; associate professor 1892; 1894 professor of Latin in the University of Chicago. He has written ‹Repetition in Latin› (1900), a ‹History of Roman Political Institutions› (1901), and philological work.

Abbott, Gorham Dummer, American educator, brother of Jacob and J. S. C.: b. Hallowell, Me., 3 Sept. 1807; d. 31 July 1874. He graduated at Bowdoin 1826, at Andover 1831. Ordained a Congregational clergyman, he became a teacher in New York; in 1845 with his brothers he established the Abbott Institute for females in New York city and in 1847 the Spingler Institute,— pioneers in women's higher education; the latter held a foremost rank in the United States for thirty years, and he left it in 1869 a rich man. He wrote didactic works, as ‹The Family at Home,› ‹Nathan W. Dickerman,› ‹Pleasure and Profit›; also ‹Mexico and the United States.›

Abbott, Jacob, a famous American juvenile writer and educator: b. Hallowell, Me., 14 Nov. 1803; d. 31 Oct. 1879. He graduated at Bowdoin 1820, studied at Andover, and was ordained a Congregational minister; professor of mathematics and natural philosophy at Amherst 1825–9; then established the Mt. Vernon girls' school in Boston, and in 1834 organized and was pastor of the Eliot Church in Roxbury. In 1839 he removed permanently to Farmington, Me., and devoted himself to literary work there and in New York, assisting also in female education (see the preceding title), writing extensively for the early ‹Harper's Monthly,› of which he was one of the chief bulwarks, traveling widely abroad, and writing the classic juveniles of which the ‹Rollo Books› are the best known type,— neither their usefulness, their popularity, nor their charm, has yet vanished. He had an excellent dramatic sense, a healthy balance, a sound business practicality and a true understanding of and sincere sympathy with children, which makes his didactics charming to rightly constituted children; no boys and girls were ever less priggish than those in ‹Rollo,› the conventional burlesques of which merely prove that the authors have not read the books, and even so are a testimony to their vitality. The chief of his more than 200 volumes are the ‹Rollo Books,› (28 vols.), the ‹Lucy Books› (6 vols.), the ‹Jonas Books› (6 vols.), the ‹Franconia Stories› (10 vols.), the ‹Marco Paul Series› (6 vols.), the ‹Gay Family› series (12 vols.), the ‹Juno Books› (6 vols.), the ‹Rainbow Series› (5 vols.), and several other series of science and travel for the young; more than 20 of the series of illustrated histories to which his brother J. S. C. contributed, and 8 vols. of American history. He also edited historical text-books and compiled school readers.

Abbott, Sir John Joseph Caldwell, Canadian statesman: b. St. Andrews, Quebec, 12 March 1821; d. 1893. Graduated at McGill College, Montreal, he became a lawyer, and was regarded among the best Canadian authorities on commercial law, being dean of the McGill College Law Faculty for ten years. In 1859 he was elected to the Lower House of Quebec, representing Argenteuil till the union of the Provinces in 1867, when he was returned to the Canadian House of Commons. In 1862 he was solicitor-general in the Sandfield Macdonald-Sicotte Cabinet. In 1887 he joined Sir John A. Macdonald's Cabinet as minister without portfolio, and on Macdonald's death in June 1891 was made premier of the Dominion; but resigned from ill health November 1892, accepting a seat without portfolio in the Cabinet of his successor, Sir John Thomson.

Abbott, John Stephens Cabot, American author: b. Brunswick, Me., 18 Sept. 1805; d. Fairhaven, Conn., 17 June 1877. He graduated at Bowdoin 1825, and Andover; was ordained Congregational minister 1830, and held pastorates at Worcester, Roxbury, and Nantucket, Mass. He resigned the ministry in 1844 and devoted himself to popular literature. A fertile writer like his brother Jacob, and with an interest in his own matter that gave a certain charm to his style and excited equal interest in uncritical readers, but with too little acumen and too much rhetoric for the solid historical subjects he had a passion for, he issued very many works useful in stimulating public curiosity in history, but of too little weight to endure. The most famous was the ‹Life of Napoleon› contributed as a serial to ‹Harper's Magazine,› and a great popular success; others were ‹The French Revolution,› ‹Napoleon at St. Helena,› ‹The Civil War in America› (1863–6), ‹Napoleon III.› (1868), ‹Romance of Spanish History› (1879), ‹Frederick the Great› (1871), and many volumes of small histories and biographies.

Abbott, Lyman, American clergyman and editor, third son of Jacob: b. Roxbury, Mass., 18 Dec. 1835. He graduated at the University of the City of New York in 1853; studied law, and went into partnership with his brothers Austin and Benjamin in 1856; but feeling more bent for the ministry studied theology with his uncle John S. C., and was ordained 1860. Till 1865 he was pastor at Terre Haute, Ind.; 1865–8 secretary of the Freedmen's Commission, residing in New York, also becoming pastor of the New England Church there; in 1869 resigned his pastorate for journalism and literature. He was in succession editor of the «Literary Record» department of ‹Harper's Magazine,› and at the same time chief editor of the ‹Illustrated Christian Weekly›; then associ-

ate editor with Henry Ward Beecher of the ‹Christian Union,› now the ‹Outlook,› of which he became chief editor on Mr. Beecher's death in 1887, succeeding him also in the Plymouth Church pulpit, which he resigned in 1899 to devote himself wholly to literary work. His earliest books were two novels in collaboration with his brothers (see ABBOTT, AUSTIN). He has written a ‹Life of Jesus› (1869), ‹Old Testament Shadows of New Testament Truths› (1870), ‹A Dictionary of Bible Knowledge› and ‹A Layman's Story› (1872), ‹Commentary on the New Testament› (4 vols., 1875 sq.), ‹Life of Henry Ward Beecher› (1883), ‹Evolution of Christianity› (1892), ‹Christianity and Social Problems› (1896), ‹The Theology of an Evolutionist› (1897), ‹Life and Letters of Paul› (1898), ‹Life and Literature of the Ancient Hebrews' (1901), 'The Rights of Man' (1901), 'Personality of God' (1905), etc.; besides editing volumes of Beecher's sermons and devotional exercises from his writings.

Abbott, Russell Bigelow, D.D., American educator: b. Brookville, Ind., 8 Aug. 1823; graduated at the University of Indiana 1847. After several years as principal of public schools in Muncie and New Castle, Ind., and of Whitewater Presbyterian Academy, he was ordained in the Presbyterian Church, 1857; held pastorates in Indiana and Minnesota 24 years, 15 in Albert Lea, Minn.; and founding Albert Lea College there became its president in 1884. Dr. Abbott has been a leading force in his Church body.

Abbreviations or «shortenings» are used in writing to save time and space, or it may be to ensure secrecy. The ancient copiers of MSS. invented many contractions to facilitate their labor. Greek MSS. abound in such, and hence often cannot be read without a previous regular study of Greek palæography. From MSS. these contractions were transferred to the printed editions of Greek authors, and have only been wholly disused within the past century; hence regular lists of them were given in the earlier Greek grammars, because the knowledge of them was absolutely essential to the student. Some of the commoner are still given in some grammars, as many Greek works are accessible only in editions full of them. Among the Romans the marks of abbreviation, called *notæ* or *compendia scribendi*, were so numerous that, in a classification by L. Annæus Seneca, they amount to 5,000. With the Latin language the ancient Roman abbreviations passed to the Middle Ages, appearing first on inscriptions and coins, then in manuscripts, and, more especially after the 11th century, in charters and other legal documents. The use of them in legal documents was forbidden by an act of Parliament passed in the reign of George II. In the following list most of the abbreviations that are likely to be met with by modern readers are alphabetically arranged, save chemical elements, for which see table of ATOMIC WEIGHTS. The standard abbreviations used in library catalogues are also given. (For Latin abbreviations see Campelli's ‹Dizionario di Abbreviature›: Milan, 1899).

A.— Acre; Acting; Accept.
A: (Lib. cat.).— Augustus.
A.. (Lib. cat.).— Anna.
A. or Ans.— Answer.
A. A.— Associate of Arts.
A. A. A. G.— Acting Assistant Adjutant-General.
A. A. A. S.— American Association for the Advancement of Science.
A. A. G.— Assistant Adjutant-General.
A. A. P. S.— American Association for the Promotion of Science.
A. A. S.— *Academiæ Americanæ Socius,* Fellow of the American Academy (of Arts and Sciences).
A. A. S. S.— *Americanæ Antiquarianæ Societatis Socius,* Member of the American Antiquarian Society.
A. B.— Able-bodied seaman; *Artium Baccalaureus,* Bachelor of Arts.
A. B. C. F. M.— American Board of Commissioners for Foreign Missions.
Abl.— Ablative.
Abp.— Archbishop.
Abr.— Abridgment, or Abridged.
A. B. S.— American Bible Society.
a/c — Account.
A. C.— *Ante Christum,* before the birth of Christ; Arch-chancellor.
Acad.— Academy.
Acad. Nat. Sci.— Academy of Natural Sciences.
Acc.— Accusative.
Acct.— Account.
A. C. S.— American Colonization Society.
Act.— Active; Acting.
Ad.— Advertisement.
A. D.— *Anno Domini,* in the year of the Lord.
A. D. C.— Aide-de-camp.
Adj.— Adjective.
Adjt.— Adjutant.
Adjt.-Gen.— Adjutant-General.
Ad lib.— *Ad libitum,* at pleasure.
Adm.—Admiral; Admiralty.
Adm. Co.— Admiralty Court.
Admr.— Administrator.
Admx.— Administratrix.
Ads.— *Ad sectam,* at the suit [of].
Ad v.— *Ad valorem,* at (or on) the value.
Advt.— Advertisement.
A. E. I. O. U. (The Austrian device) — *Austriæ est imperare orbi universo,* or *Alles Erdreich Ist Öesterreich Unterthan,* «It is given to Austria to rule the whole earth."
Æt.— *Ætatis,* of age; aged.
A. F. B. S.— American and Foreign Bible Society.
Afr.— African.
A. G.— Adjutant-General.
Agl. Dept.— Agricultural Department (Department of Agriculture).
Agr.—Agriculture.
A. G. S. S.— American Geographical and Statistical Society.
Agt.— Agent.
A. H.— *Anno Hegiræ,* in the year of the Hegira (Mohammedan era).
A. H. M. S.— American Home Missionary Society.
Ala.— Alabama.
Alas.— Alaska.
Alb.— Albany.
Alban.— Albanian.
Ald.— Alderman.
Alex.— Alexander.
Alf.— Alfred.
Alg.— Algebra.
Alt.— Altitude.

Am.— American; Amos.
A. M.— *Ante meridiem*, before noon; morning; *Anno mundi*, in the year of the world; *Artium Magister*, Master of Arts.
Am. Ass. Adv. Sci.— American Association for the Advancement of Science.
Amb.— Ambassador.
Amer.— American.
Amer. Acad.— American Academy.
A. M. E. Z.— African Methodist Episcopal Zion.
Amm.— *Amalgama*, amalgamation.
Amt.— Amount.
An.— *Anno*, in the year.
A. N. A.— Associate of the National Academy.
An. A. C.— *Anno ante Christum*, in the year before Christ.
Anal.— Analysis.
Anat.— Anatomy.
Anc.— Ancient; anciently.
And.— Andrew.
Ang.-Sax.— Anglo-Saxon.
Ann.— *Annales*, annals.
Anon.— Anonymous.
Ans.— Answer.
Ant., or Antiq.— Antiquities.
Anth.— Anthony.
Aor.— Aorist.
A. O. S. S.— *Americanæ Orientalis Societatis Socius*, Member of the American Oriental Society.
Ap.— Apostle; Appius; *Apud*, in writings of; as quoted by.
Apo.— Apogee.
Apoc.— Apocalypse.
Apocr.— Apocrypha.
App.— Appendix.
Apr.— April.
Aq.— *Aqua*, water.
A. Q. M.— Assistant Quartermaster.
A. Q. M. G.— Assistant Quartermaster-General.
A. R.— *Anna Regina*, Queen Anne; *Anno regni*, in the year of the reign.
Ara.— Arabic.
A. R. A.— Associate of the Royal Academy.
Arch.— Archibald; Architect; Architecture.
Archd.— Archdeacon.
Arg.— *Arguendo*, in arguing, or in the course of argument; *argumento*, by an argument drawn from such a law.
Ari.— Arizona.
Arith.— Arithmetic.
Ark.— Arkansas.
Arm.— Armenian.
Armor.— Armoric.
Arr.— Arrive; Arrival.
A. R. R.— *Anno regni regis*, in the year of the reign of the king.
A. R. S. A.— Associate of the Royal Scottish Academy.
A. R. S. S.— *Antiquariorum Regiæ Societatis Socius*, Fellow of the Royal Society of Antiquaries.
Art.— Article.
Artil.—Artillery.
A.-S.— Anglo-Saxon.
A. S., or Assist. Sec.— Assistant-Secretary.
A. S. A.—American Statistical Association.
Ass., Assn.— Association.
A. S. S. U.— American Sunday-School Union.
Astrol.—Astrology.
Astron.—Astronomy.
At s.—At suit of.
A. T. S.— American Tract Society.
Atty.— Attorney.
Atty.-Gen.— Attorney-General.
At. Wt.— Atomic weight.
A. U. A.— American Unitarian Association.
A. U. C.— *Anno urbis conditæ*, or *ab urbe condita*, in the year from the building of the city (Rome).
Aug.— August.
Aus.— Austria; Austrian.
Auth. Ver., or A. V.— Authorized Version (of the Bible).
Av.— Avenue; Average; Avoirdupois.
Ave.— Avenue.
Avdp. or Avoir.— Avoirdupois.
A. Y. M.— Ancient York Masons.

B.— Born.
B: (Lib. cat.).— Benjamin.
B.. (Lib. cat.).— Beatrice.
B. A.— Bachelor of Arts.
Bal.— Balance.
Balt.— Baltimore.
B. & F.— Beaumont and Fletcher.
Bapt.— Baptist.
Bar.— Barometer; Baruch.
Bart.— Baronet.
Bbl.— Barrel.
B. C.— Before Christ; British Columbia.
B. C. L.— Bachelor of Civil Law.
B. D.— *Baccalaureus Divinitatis*, Bachelor of Divinity.
Bdls.— Bundles.
Bds.— Boards; Bonds.
Beau. & Fl.— Beaumont and Fletcher.
Beds.— Bedfordshire.
Belg.— Belgic; Belgian; Belgium.
Benj.— Benjamin.
Berks.— Berkshire.
B. I.— British India.
Bib.—Bible; Biblical.
Bibliog.— Bibliographical; Bibliography.
Biog.—Biography; Biographical.
Bisc.— Biscayan.
B. Jon.— Ben Jonson.
Bk.— Bark; Book.
B. LL.— *Baccalaureus Legum*, Bachelor of Laws.
Bls.— Bales.
B. M.— *Baccalaureus Medicinæ*, Bachelor of Medicine.
Bohem.— Bohemian
Bost.— Boston.
Bot.— Botany.
Bp.— Bishop.
Br.— Brig; British; Brother.
B. R.—*Banco Regis*, or *Reginæ*, the King's or Queen's Bench.
Braz.— Brazil; Brazilian.
Brig.— Brigade; Brigadier.
Brig.-Gen.— Brigadier-General.
Brit. Mus.— British Museum.
Bro.— Brother.
B. S.— Bachelor in the Sciences.
Bt.— Baronet.
Bu.— Bushel; Bushels.
Bucks.— Buckinghamshire.
Burl.— Burlesque.
B. V.— *Beata Virgo*, Blessed Virgin; *Bene vale*, farewell.
Bx., Bxs.—Box; Boxes.

C.— *Caput* or *capitulum*, chapter; Celsius; Cent; Centigrade; Cents; *Centum*, a hundred; Century; *Circa* or *circiter*, about; Consul.
C: (Lib. cat.).— Charles.

C.. (Lib. cat.).— Charlotte.
Ca. (*circa*)— About.
C. A.— Chief Accountant; Commissioner of Accounts.
Cæt. par.— *Cæteris paribus*, other things being equal.
Cal.—California; Calends.
Cam., Camb.— Cambridge.
Can.— Canon.
Cant.— Canticles.
Cantab.— *Cantabrigiæ, Cantabrigiensis*, of Cambridge.
Cantuar.— *Cantuariæ, Cantuariensis*, of Canterbury.
Cap.— *Caput, capitulum*, chapter.
Caps.— Capitals.
Capt.— Captain.
Capt.-Gen.— Captain-General.
Car.— Carat.
Card.— Cardinal.
Ca. resp.— *Capias ad respondendum*, that you take to answer,— a legal writ.
Cas.— Cases.
Ca. sa.— *Capias ad satisfaciendum*, that you take to satisfaction,— a legal writ.
Cash.—Cashier.
Cat.— Catalogue.
Cath.— Catherine, Catholic, Cathedral.
C. B.— Cape Breton; *Communis Bancus*, Common Bench; Companion of the Bath.
C. C.— Caius College; *Compte courante*, account current; Circuit Court; County Commissioner; County Court; Cubic centimeter.
C. C. C.— Corpus Christi College.
C. C. P.— Court of Common Pleas.
C. E.— Civil Engineer.
Cel., or Celt.— Celtic.
Cels.— Celsius.
Cent.— Centigrade, a scale of 100° from freezing to boiling; Central; *Centum*, a hundred; Century.
Cert.— Certify.
Certif.—Certificate.
Cf.— *Confer*, compare.
C. f. & i.— Cost, freight, and insurance.
C. G.— Commissary-General; Consul-General.
C. G. H.— Cape of Good Hope.
Ch.— Chapter; Charles; Chief; China; Chinese; Church.
C. H.— Court house.
Chal. or Chald.— Chaldaic; Chaldea; Chaldean; Chaldron.
Chanc.— Chancellor.
Chap.— Chapter.
Chas.— Charles.
Chem.— Chemistry.
Ches.— Chesapeake.
Chic.— Chicago.
Ch. J.— Chief Justice.
Chr.— Christ; Christian; Christopher; Chronicles.
Chron.— Chronicles.
Cic.— Cicero.
Cin.— Cincinnati.
Circ.— *Circa*, or *circiter*, about; Circuit.
Cit.— Citation; Cited; Citizen.
Civ.— Civil.
C. J.— Chief Justice.
Cld.— Cleared.
Clk.— Clerk.
C. M.— Common Meter.
C. M. G.— Companion of the Order of St. Michael and St. George.

Co.— Company; county.
Coch., or Cochl.— *Cochlear*, a spoonful. *C. amp.* (*amplum*), a tablespoonful. *C. mag.* (*magnum*), a large spoonful. *C. med.* (*medium*), a dessert-spoonful. *C. parv.* (*parvum*), a small spoonful or teaspoonful.
C. O. D.— Cash (or collect) on delivery.
Col.— Colorado; Colonel; Colossians.
Coll.— Collector; Colloquial; College; Collection.
Colo.— Colorado.
Com.— Commerce; Committee; Commissioner; Commodore.
Comdg.— Commanding.
Comm.— Commentary.
Comp.— Compare; Comparative; Compound; Compounded.
Com. Ver.—Common Version (of the Bible).
Con.— *Contra*, against; in opposition.
Conch.— Conchology.
Con. Cr.— Contra credit.
Confed.— Confederate.
Cong.— Congress.
Congl.— Congregational; Conglomerate.
Conj.— Conjunction.
Conn., or Ct.— Connecticut.
Con. Sec.— Conic sections.
Const.— Constable; Constitution.
Cont.— Continued; contra.
Cop., or Copt.— Coptic.
Cor.— Corinthians.
Cor. Mem.—Corresponding Member.
Corn.— Cornwall; Cornish.
Corol.— Corollary.
Cor. Sec.— Corresponding Secretary.
Cos.— Cosine.
Coss.— *Consules*, Consuls.
Cp.— Compare.
C. P.— Common Pleas; Court of Probate.
C. P. S.— *Custos Privati Sigilli*, Keeper of the Privy Seal.
Cr.— Credit; Creditor; Criminal.
C. R.— *Carolus Rex*, King Charles; *Custos Rotulorum*, Keeper of the Rolls.
Crim. Con.— Criminal conversation (adultery).
C. S.— Court of Sessions; *Custos Sigilli*, Keeper of the Seal.
C. S. A.—Confederate States of America; Confederate States Army.
Csk.— Cask.
C. S. N.— Confederate States Navy.
C. Theod.— *Codice Theodosiano*, in the Theodosian Code.
Ct.— Connecticut; Court.
Ctl.— Cental.
Cts.— Cents.
Cu., or Cub.— Cubic.
Cur.— Currency.
Curt.— Current.
C. W.—Canada West.
Cwt.— Hundredweight.
Cyc.— Cyclopedia.

D.— Day; Days; *Denarius*, penny, pence; Died
D: (Lib. cat.).— David.
D.. (Lib. cat.).— Delia.
D. A. G.— Deputy Adjutant-General.
Dak.—Dakota.
Dan.— Daniel; Danish.
Dat.— Dative.
D. B. or Domesd. B.—Domesday Book.
D. C.— *Da capo*, again; District of Columbia.
D. C. L.—Doctor of Civil Law.

D. C. S.—Deputy Clerk of Sessions.
D. D.—*Divinitatis Doctor*, Doctor of Divinity.
D. D. S.—Doctor of Dental Surgery.
Dea.—Deacon.
Dec.—December; Declination.
Dec. of Ind.—Declaration of Independence.
Def.—Definition.
Def., Deft.—Defendant.
Deg.—Degree; degrees.
Del.—Delaware; Delegate; *Delineavit*, he (or she) drew it.
Dem.—Democrat; Democratic.
Dep.—Deputy.
Dept.—Department.
Deut.—Deuteronomy.
D. F.—Defender of the Faith.
D. G.—*Dei gratia*, by the grace of God; *Deo gratias*, thanks to God.
D. H.—Dead-head.
Diam.—Diameter.
Dict.—Dictionary; Dictator.
Dim.—Diminutive.
Diosc.—Dioscorides.
Disc.—Discount.
Diss.—Dissertation.
Dist.—District.
Div.—Division.
D. L. O.—Dead-Letter Office.
D. M.—Doctor of Music.
Do.—*Ditto*, the same.
Doc.—Document.
Dols.—Dollars.
D. O. M.—*Deo optimo maximo*, to God, the best, the greatest.
Doz.—Dozen.
D. P.—Doctor of Philosophy.
Dpt.—Department.
Dr.—Debtor; Doctor; Drachms.
D. S.—*Dal segno*, from the sign.
D. Sc.—Doctor of Science.
D. T.—*Delirium tremens; Doctor Theologiæ*, Doctor of Theology.
Dub.—Dublin.
D. V.—*Deo volente*, God willing.
Dwt.—Pennyweight.
Dyn.—Dynamics.

E.—East.
E: (Lib. cat.).—Edward.
E.. (Lib. cat.).—Elizabeth.
Ea.—Each.
E. & O. E.—Errors and omissions excepted.
E. B.—English Bible.
Eben.—Ebenezer.
Ebor.—*Eboracum*, York.
Eccl.—Ecclesiastes.
Ecclus.—Ecclesiasticus.
Ed.—Editor; Edition.
E. D.—Eastern District.
Edin.—Edinburgh.
Edm.—Edmund.
Edw.—Edward.
E. E.—Errors excepted.
E. E. T. S.—Early English Text Society.
E. Fl.—Ells Flemish.
E. Fr.—Ells French.
E. G.—*Exempli gratia*, for example; *Ex grege*, among the rest.
E. I.—East Indies or East India.
E. I. C. S.—East India Company's Service.
Eliz.—Elizabeth.
E. Lon.—East longitude.
E. M.—Mining Engineer.
Emp.—Emperor; Empress.
Encyc.—Encyclopedia.
Encyc. Amer.—Encyclopedia Americana.
E.N.E.—East-northeast.
Eng.—Engineering; Engineers; England; English.
Ent., Entom.—Entomology.
Env. Ext.—Envoy Extraordinary.
Eod.—Every other day.
Eow.—Every other week.
Ep.—Epistle.
Eph.—Ephesians; Ephraim
Epis.—Episcopal.
E. S.—Ells Scotch.
Esd.—Esdras.
E.S.E.—East-southeast.
Esq.—Esquire.
Esth.—Esther.
E. T.—English Translation.
Et al.—*Et alii*, and others.
Etc., or &c.—*Et cæteri, et cæteræ, et cætera*, and others; and so forth.
Eth.—Ethiopic; Ethiopian.
Et seq.—*Et sequentes, et sequentia*, and what follows.
Etym.—Etymological; Etymology.
E. U.—*États Unis*, United States; Evangelical Union.
Ex.—Example; Exodus.
Exc.—Excellency; exception.
Exch.—Exchequer; Exchange.
Ex. Doc.—Executive Document.
Exec.—Executive; Executor.
Execx.—Executrix.
Ex. gr.—*Exempli gratia*, for example.
Exon.—*Exonia*, Exeter; *Exoniæ, Exoniensis*, of Exeter.
Ex p.—*Ex parte*, in behalf of.
Exr.—Executor.
Ez.—Ezra.
Ezek.—Ezekiel.

F.—Fahrenheit; Farthing; Fathom; Fathoms; Forte; Franc; France; Francs; French; Friday.
F: (Lib. cat.).—Frederick.
F.. (Lib. cat.).—Fanny.
Fahr.—Fahrenheit.
F. and A. M.—Free and Accepted Masons.
F. A. S.—Fellow of the Antiquarian Society.
F. B. S.—Fellow of the Botanical Society.
F. C.—Free Church of Scotland.
Fcap. or fcp.—Foolscap.
F. C. P. S.—Fellow of the Cambridge Philological Society.
F. C. S.—Fellow of the Chemical Society.
F. D.—*Fidei Defendor*, Defender of the Faith.
F. E.—Flemish ells.
Feb.—February.
Fec.—*Fecit*, he did or made it.
Fed.—Federal.
Fem.—Feminine.
F. E. S.—Fellow of the Entomological Society; Fellow of the Ethnographical Society.
Ff.—*Fecerunt*, they did or made it; Folios; Following; Fortissimo.
F. F. V.—First Families of Virginia.
F. G. S.—Fellow of the Geological Society.
F. H. S.—Fellow of the Horticultural Society.
Fid. Def.—*Fidei Defendor*, Defender of the Faith.
Fi. fa.—*Fieri facias*, that you cause to be done or made,—a writ of execution.

Fig.— Figure.
Fin.— Finland.
Finn.— Finnish.
Fir.— Firkin.
F. K. Q. C. P. I.— Fellow of King's and Queen's College of Physicians, Ireland.
Fl.— Florin; Florins; Flourished.
Fla.— Florida.
Fl. E.— Flemish ells.
F. L. S.— Fellow of the Linnæan Society.
Fm.; Fms.— Fathom; Fathoms.
F.-M.— Field-Marshal.
Fo.— Folio.
F.-O.— Field-Officer.
F. o. b.— Free on board.
Fol.— Folio.
For.— Foreign.
F. P. S.— Fellow of the Philological Society.
Fr.— *Fragmentum,* fragment; Franc; France; Francis; Francs; French; From.
F. R. A. S.— Fellow of the Royal Asiatic Society; Fellow of the Royal Astronomical Society.
F. R. C. P.— Fellow of the Royal College of Physicians.
F. R. C. S. (E., I., or L.).— Fellow of the Royal College of Surgeons (Edinburgh, Ireland, or London).
Fr. E.— French ells.
Fred.— Frederick.
F. R. G. S.— Fellow of the Royal Geographical Society.
F. R. Hist. Soc.— Fellow of the Royal Historical Society.
Fri.— Friday.
Frs.— Frisian.
F. R. S.— Fellow of the Royal Society.
F. R. S. E.— Fellow of the Royal Society, Edinburgh.
F. R. S. L.— Fellow of the Royal Society, London.
F. R. S. S. A.— Fellow of the Royal Scottish Society of Arts.
F. S. A.— Fellow of the Society of Arts, or of Antiquaries.
F. S. A. E.— Fellow of the Society of Antiquaries, Edinburgh.
F. S. A. Scot.— Fellow of the Society of Antiquaries of Scotland.
F. S. S.— Fellow of the Statistical Society.
Ft.— Foot; feet; Fort.
Fth.— Fathom.
Fur.— Furlong.
F. Z. S.— Fellow of the Zoological Society.

G.— Guineas.
G: (Lib. cat.).— George.
G.. (Lib. cat.).— Grace.
Ga.— Georgia.
G. A.— General Assembly.
Galv.— Galvanism; Galveston.
G. A. R.— Grand Army of the Republic.
G. B.— Great Britain.
G. B. & I.— Great Britain and Ireland.
G. C.— Grand Chapter; Grand Conductor; Grand Cross.
G. C. B.— Grand Cross of the Bath.
G. C. H.— Grand Cross of Hanover.
G. C. K. P.— Grand Commander of the Knights of St. Patrick.
G. C. L. H.— Grand Cross of the Legion of Honor.
G. C. M. G.— Grand Cross of St. Michael and St. George.
G. C. S. I.— Grand Commander of the Star of India.
G. D.— Grand Duke; Grand Duchess.
G. E.— Grand Encampment.
Gen.— Genealogy; Genera; General; Genesis; Genus.
Gent.— Gentleman.
Geo.— George.
Geog.— Geography.
Geol.— Geology.
Geom.— Geometry.
Ger.— German; Germany.
Gl., or Gloss.— Glossary.
G. L.— Grand Lodge.
G. M.— Grand Master.
G. M. K. P.— Grand Master of the Knights of St. Patrick.
G. M. S. I.— Grand Master of the Star of India.
G. O.— General Order.
Goth.— Gothic.
Gov.— Governor.
Gov.-Gen.— Governor-General.
Govt.— Government.
G. P.— *Gloria Patri,* « Glory be to the Father.»
G. P. O.— General Post-Office.
Gr.— Greek; Gross.
G. R.— *Georgius Rex,* King George.
Gr., Grs.— Grain; Grains.
Grad.— Graduated.
Gram.— Grammar.
Grot.— Grotius.
G. S.— Grand Secretary; Grand Sentinel; Grand Scribe.
G. T.— Good Templars; Grand Tyler
Gtt.— *Gutta* or *guttæ,* drop; drops.

H.— Hour.
H: (Lib. cat.).— Henry.
H.. (Lib. cat.).— Helen.
H. A.— *Hoc anno,* this year.
Hab.— Habakkuk.
Hab. corp.— *Habeas corpus,* that you have the body.
Hab. fa. poss.— *Habere facias possessionem,* that you cause to have possession,— a legal writ.
Hab. fa. seis.— *Habere facias seisinam,* that you cause to have seisin,— a legal writ.
Hag.— Haggai.
Hants.— Hampshire.
H. B. C.— Hudson Bay Company.
H. B. M.— His or Her Britannic Majesty.

H. C.— House of Commons; Heralds' College.
H. C. M.— His or Her Catholic Majesty.
Hdkf.— Handkerchief.
H. E.— His Excellency; *Hoc est,* that is, or this is.
Heb.— Hebrew; Hebrews.
H. E. I. C. S.— Honorable East India Company's Service.
Her.— Heraldry.
Herp.— Herpetology.
Hf.-bd.— Half-bound.
H. G.— Horse Guards.
H. H.— His or Her Highness; His Holiness (the Pope).
Hhd.— Hogshead.
H. I.— Hawaiian Islands.
Hier.— *Hierosolyma,* Jerusalem.
H. I. H.— His or Her Imperial Highness.
Hil.— Hilary.
Hind.— Hindu; Hindustan; Hindustanee.
Hipp.— Hippocrates.

Hist.— Historical; History.
H. J. S.— *Hic jacet sepultus*, here lies buried.
H. L.— House of Lords.
H. M.— His or Her Majesty.
H. M. P.— *Hoc monumentum posuit*, erected this monument.
H. M. S.— His or Her Majesty's Ship or Service.
Holl.— Holland.
Hon.— Honorable.
Hort.— Horticulture.
Hos.— Hosea.
H.-P.— High-priest; Horse-power; Half-pay.
Hr.— Hour.
H. R.— House of Representatives
H. R. E.— Holy Roman Empire.
H. R. H.— His or Her Royal Highness.
H. R. I. P.— *Hic requiescit in pace*, Here rests in peace.
H. S.— *Hic situs*, Here lies.
H. S. H.— His or Her Serene Highness.
H. T.— *Hoc titulum*, this title; *hoc titulo*, in or under this title.
Hund.— Hundred.
Hung.— Hungarian.
H. V.— *Hoc verbum*, this word; *his verbis*, in these words.
Hyd.—Hydraulics; Hydrostatics.
Hypoth.— Hypothesis; Hypothetical.

I.— Island.
I: (Lib. cat.).— Isaac.
I.. (Lib. cat.).— Isabella.
Ia.— Iowa.
Ib., or ibid.— *Ibidem*, in the same place.
Icel.— Iceland; Icelandic.
Ich., or Ichth.— Ichthyology.
Icon. Encyc.— Iconographic Encyclopedia.
I. Ch. Th. U. S.—'Ι(ησοῦς) Χ(ριστὸς) Θ(εοῦ) Υ(ἱὸς) Σ(ωτήρ) (*Iesous Christos, Theou Uios, Soter*), Jesus Christ, the Son of God, the Saviour; also written Ιχθὺς = a fish; whence the symbol of a fish for the sacred name.
Id.— *Idem*, the same; *Idus*, the Ides; Island.
Ida.— Idaho.

Ind. T., or Ind. Ter.— Indian Territory.
I. H. P.— Indicated horse-power.
Ind.— Indiana; Index.
I. N. D.— *In nomine Dei*, in the name of God.
Indef.— Indefinite.
Inf.— *Infra*, beneath, or below.
In f.— *In fine*, at the end.
Inhab.— Inhabitant; Inhabited.
In lim.— *In limine*, at the outset.
In loc.— *In loco*, in the place.
In pr.— *In principio*, in the beginning.
I. N. R. I.— *Jesus Nazarenus, Rex Judæorum*, Jesus of Nazareth, King of the Jews.
Inst.—Instant; Institute; Institutes; Institution.
Int.—Interest.
Int. Dept.— Department of the Interior.
Interj.—Interjection.
In trans.— *In transitu*, in transit.
Int. Rev.— Internal Revenue.
Introd.— Introduction.
Ion.— Ionic.
I. O. O. F.— Independent Order of Odd Fellows.
I. O. S. M.— Independent Order of the Sons of Malta.
I. O. U.— I owe you.
Ipecac.— Ipecacuanha.
I. Q.— *Idem quod*, the same as.
Ire.— Ireland.
I. R. O.— Internal Revenue Office.
Is., Isl.— Island; Islands.
Isa.— Isaiah.
It.— Italy.
I. T.— Inner Temple.
Ital.— Italic; Italian.
I. W.— Isle of Wight.

J.— Justice, or Judge.
J: (Lib. cat.).— John.
J.. (Lib. cat.).— Jane.
J. A.— Judge-Advocate.
Jac.— Jacob; *Jacobus*, James.
J. A. G.— Judge Advocate-General.
Jam.— Jamaica.
Jan.— January.
Jas.— James.
Jc.— Junction.
J. C.— *Jurisconsultus*, jurisconsult.
J. C. D.— *Juris Civilis Doctor*, Doctor of Civil Law.
J. D.— Junior Deacon.
Jer.— Jeremiah.
J. G. W.— Junior Grand Warden.
JJ.— Justices.
Jno.— John.
Jona.— Jonathan.
Jos.— Joseph.
Josh.— Joshua.
J. P.—Justice of the Peace.
J. Prob.— Judge of Probate.
Jr.— Junior.
J. R.— *Jacobus Rex*, King James.
Jud.— Judicial; Judith.
J. U. D., or J. V. D.— *Juris utriusque Doctor*, Doctor of both laws (of the Canon and the Civil Law).
Judg.— Judges.
Judge-Adv.— Judge-Advocate.
Jul. Per.— Julian Period.
Jun.— Junior.
Junc.— Junction.
Jus. P.— Justice of the Peace.
Just.— Justinian.
J. W.— Junior Warden.

K.— Karat; Karats; King.
K: (Lib. cat.).— Karl.
K.. (Lib. cat.).— Katharine.
K. A.— Knight of St. Andrew, in Russia.
Kal.— *Kalendæ*, the Kalends.
Kan.— Kansas.
K. A. N.— Knight of Alexander Nevskoi, in Russia.
K. B.— King's Bench; Knight of the Bath.

Mch.— March.
M. C. S.— Madras Civil Service.
Md.— Maryland.
M. D.— *Medicinæ Doctor,* Doctor of Medicine.
Mdlle.— Mademoiselle.
Mdse.— Merchandise.
Me.— Maine.
M. E.— Methodist Episcopal; Military or Mechanical Engineer.
Mech.— Mechanic; Mechanical.
Med.— Medicine.
M. E. G. H. P.— Most Excellent Grand High Priest.
Mem.— *Memento,* remember; Memorandum.
Merc.— Mercury.
M. E. S.— Methodist Episcopal, South.
Mess. & Docs.— Messages and Documents.
Messrs.—*Messieurs,* Gentlemen.
Met.— Metaphysics.
Metal.— Metallurgy.
Meteor.— Meteorology.
Meth.— Methodist.
Mex.— Mexico, or Mexican.
M. F. A.— Minister of Foreign Affairs.
Mfd.— Manufactured.
Mfg.— Manufacturing.
M. F. H.— Master of Foxhounds.
Mfrs.— Manufacturers.
Mfs.— Manufactures.
M. Goth.— Mœso-Gothic.
Mic.— Micah.
M. I. C. E.— Member of the Institution of Civil Engineers.
Mich.— Michael; Michaelmas; Michigan.
Mil.— Military.
Min.— Mineralogy; Mining; Minute, minutes.
Minn.— Minnesota.
Min. Plen.— Minister Plenipotentiary.
Mir. for Mag.— Mirror for Magistrates.
Miss.— Mississippi.
M. L. A.— Mercantile Library Association.
MM.— *Messieurs,* Gentlemen; (Their) Majesties.
Mme.— *Madame,* Madam.
M. M. S.— Moravian Missionary Society.
M. M. S. S.— *Massachusettensis Medicinæ Societatis Socius,* Fellow of the Massachusetts Medical Society.
M. N. A. S.— Member of the National Academy of Sciences.
Mo.— Missouri; Month.
Mod.— Modern.
Mon.— Montana; Monday.
Mons.— *Monsieur,* Sir.
Mont.— Montana.
Morn.— Morning.
Mos.— Months.
M. P.— Member of Parliament; Member of Police; Methodist Protestant.
M. P. P.— Member of Provincial Parliament.
M. P. S.— Member of the Philological Society; Member of the Pharmaceutical Society.
Mr.—Mister.
M. R.— Master of the Rolls.
M. R. A. S.— Member of the Royal Asiatic Society; Member of the Royal Academy of Science.
M. R. C. C.— Member of the Royal College of Chemistry.
M. R. C. P.— Member of the Royal College of Preceptors.
M. R. C. S.— Member of the Royal College of Surgeons.

M. R. G. S.— Member of the Royal Geographical Society.
M. R. I.— Member of the Royal Institution.
M. R. I. A.— Member of the Royal Irish Academy.
Mrs.— Mistress.
M. R. S. L.— Member of the Royal Society of Literature.
MS.— *Manuscriptum,* manuscript.
M. S.— Master of Science; *Memoriæ sacrum,* sacred to the memory.
M. S. A.— Master of Science in Agriculture.
M. S. L.— Mean sea level.
MSS.— *Manuscripta,* manuscripts.
Mt.— Mount, or mountain.
M. T. C.— Marcus Tullius Cicero.
Mth; Mths.— Month; Months.
Mus. B.— *Musicæ Baccalaureus,* Bachelor of Music.
Mus. D.— *Musicæ Doctor,* Doctor of Music.
M. W.— Most Worthy; Most Worshipful.
M. W. G. C. P.— Most Worthy Grand Chief Patriarch.
M. W. G. M.— Most Worthy Grand Master; Most Worshipful Grand Master.
M. W. P.— Most Worthy Patriarch.
Myth.— Mythology.

N.— Neuter; North; Note; Noun; Number.
N: (Lib. cat.).— Nicholas.
N.. (Lib. cat.).— Nancy.
Na.— Nail.
N. A.— National Academician; North America; North American.
Nah.— Nahum.
Nap.— Napoleon; Napoleonic.
N. A. S.— National Academy of Sciences.
Nat.— Natural.
Nath.— Nathanael, or Nathaniel.
Nat. Ord.— Natural Order.
Naut.— Nautical.
Naut. Alm.— Nautical Almanac.
N. B.—New Brunswick; North Britain (i.e. Scotland); North British (i.e. Scotch); *Nota bene,* mark well; take notice.
N. C.— North Carolina.

N. D.— No date; Not dated; North Dakota.
N. E.—New England; Northeast.
Neb.— Nebraska.
Neh.— Nehemiah.
N. e. i.— *Non est inventus,* he is not found.
Nem. con., or nem. diss.— *Nemine contradicente,* or *nemine dissentiente,* no one opposing or dissenting; unanimously.
Neth.— Netherlands.
Neut.— Neuter (gender).
Nev.— Nevada.
N. F.— Newfoundland.
N. G.— New Granada; Noble Grand; (slang) No good.
N. H.— New Hampshire.
N. J.— New Jersey.
N. l.— *Non liquet,* it does not appear.
N. lat.— North latitude.
N. M.— New measurement; New Mexico.
N. N. E.— North-northeast.
N. N. W.— North-northwest.
No.— *Numero,* number.
N. O.— New Orleans.
Nol. Pros.— *Nolle prosequi,* unwilling to proceed.
Nom.— Nominative.
Non-com.— Non-commissioned (officer).
Non con.— Not content; dissenting (House of Lords).
Non cul.— *Non culpabilis,* not guilty.
Non obst.— *Non obstante,* notwithstanding.
Non pros.— *Non prosequitur,* he does not prosecute.
Non seq.— *Non sequitur,* it does not follow
N. o. p.— Not otherwise provided for.
Nos.— Numbers.
Notts.— Nottinghamshire.
Nov.— November.
N. P.—*Nisi Prius;* Notary Public.
N. P. D.— North Polar Distance.
N. S.— New Series; New Style (after 1752); Not specified; Nova Scotia.
N. S. J. C.—*Noster Salvator Jesus Christus,* Our Saviour Jesus Christ.
N. S. W.— New South Wales.

N. u.— Name or names unknown.
Num.— Numbers (Book of); Numeral.
N. V.— New Version.
N. V. M.— Nativity of the Virgin Mary.
N. W.— Northwest.
N. W. T.— Northwest Territory.
N. Y.—New York.
N. Z.— New Zealand.

O.— Ohio.
O: (Lib. cat.).— Otto.
O.. (Lib. cat.).— Olivia.
Ob.— *Obiit,* he or she died.
Obad.— Obadiah.
Obs.— Obsolete; Observatory; Observation.
Obt., or Obdt.— Obedient.
Oct.— October.
Oct., or 8vo.— Octavo.
O. F.— Odd Fellow, or Odd Fellows.
O. G.— Outside Guardian.
O. H. M. S.— On His or Her Majesty's Service.
O. K. (Jocular)— All right or correct.
Okl.— Oklahoma.
Olym.— Olympiad.
O. M.— Old Measurement.
Ont.— Ontario.
Opt.— Optics.
Or., Ore., Oreg.— Oregon.
Orig.— Originally.
Ornith.— Ornithology.
O. S.— Old Series; Old Style; Outside Sentinel.
O. T.— Old Testament.
O. U. A.— Order of United Americans.
Oxf.— Oxford.
Oxon.— *Oxonia,* Oxford; *Oxoniæ, Oxoniensis,* of Oxford.
Oz.— *Onza,* ounce.

P.— Page; Part; Participle; *Pondere,* by weight.
P: (Lib. cat.).— Peter.
P.. (Lib. cat.).— Pauline.
Pa., or Penn.— Pennsylvania.
Pal.— Palæontology.
Par.— Paragraph.
Parl.— Parliament.
Par. Pas.— Parallel passage.
Pathol.— Pathology.
Pat. Of.— Patent Office.
Paym.-Gen.— Paymaster-General.
Payt.— Payment.
P. B.— *Philosophiæ Baccalaureus,* Bachelor of Philosophy; Primitive Baptist.
P. C.— *Patres Conscripti,* Conscript Fathers, Senators; Postal card; Privy Council; Privy Councilor.
P. C. P.— Past Chief Patriarch.

Pref.— Preface; Preferred.
Prep.— Preparatory; Preposition.
Pres.— President.
Presb.— Presbyterian.
Prin.— Principally.
Priv.— Privative.
Pro.— Procedure.
Prob.— Probably; Problem.
Proc.— Proceedings; Procedure.
Prof.— Professor.
Pron.— Pronoun; Pronounced; Pronunciation.
Prop.— Proposition.
Prot.— Protestant.
Pro tem.— *Pro tempore*, for the time being.
Prov.— Proverbs; Province; Provost.
Prox.— *Proximo*, next (month).
Prs.— Pairs.
P. R. S.— President of the Royal Society.
Prus.— Prussia; Prussian.
Ps.— Psalm, or Psalms.
P. S.— Paddle steamer; *Post scriptum*, postscript; Privy Seal.
Psych.— Psychic; Psychical; Psychology.
Pt.— Part; Pint; Payment; Point; Port.
P. T. O.— Please turn over.
Pub.— Publisher; Publication; Published; Public.
P. v.— Post-village.
P. W. P.— Past Worthy Patriarch.
Pwt.— Pennyweight; pennyweights.
Pxt.— *Pinxit*, he (or she) painted it.

Q.—*Quadrigans*, farthing; *Quasi*, as it were, almost; Queen; Query, or question.
Q. B.— Queen's Bench.
Q. C.— Queen's College; Queen's Counsel.
Q. d.— *Quasi dicat*, as if he should say; *quasi dictum*, as if said; *quasi dixisset*, as if he had said.
Q. e.— *Quod est*, which is.
Q. e. d.— *Quod erat demonstrandum*, which was to be proved.
Q. e. f.— *Quod erat faciendum*, which was to be done.
Q. e. i.— *Quod erat inveniendum*, which was to be found out.
Q. l.— *Quantum libet*, as much as you please.
Qm.— *Quomodo*, how; by what means.
Q. M.— Quartermaster.
Q. Mess.— Queen's Messenger.
Q. M. G.— Quartermaster-General.
Q. p., or q. pl.— *Quantum placet*, as much as you please.
Qr.— Quarter.
Q. S.— *Quantum sufficit*, as much as may suffice; Quarter Sessions.
Qt.— Quart.
Qu., or qy.— *Quære*, inquire; query.
Quad.— Quadrant; Quadrate.
Quar.— Quarterly.
Que.— Quebec.
Ques.— Question.
Q. v.— *Quod vide*, which see; *Quantum vis*, as much as you will.

R.— Railroad; Railway; *Recipe*, take; *Regina*, Queen; River; Rod; Rood.
R: (Lib. cat.).— Richard.
R.. (Lib. cat.).— Rebecca.
R. A.— Royal Academician; Royal Academy; Royal Arch; Royal Artillery.
RC.— *Rescriptum*, a counterpart.
R. C.— Roman Catholic.
R. C. S.— Royal College of Surgeons.
R. C. P.— Royal College of Physicians.
R. D.— Rural Dean.
R. E.— Reformed Episcopal; Royal Engineers.
Rec.— Recipe; Record; Recorder; Recording.
Recd.— Received.
Rect.— Rector; Receipt.
Ref.— Reformed; Reformation; Reference.
Reg.— Regiment; Register; Registrar; Regular.
Reg. Prof.— *Regius Professor*, Royal Professor.
Rel.— Religion.
Rep.— Report; Reporter; Representative; Republic; Republican.
Retd.— Returned.
Rev.— Reverend; Revelation (Book of); Review; Revenue; Revise.
Rhet.— Rhetoric.
R. H. S.— Royal Humane Society; Royal Historical Society.
R. I.— Rhode Island.
R. I. P.— *Requiescat in pace*, Let him (her) rest in peace.
R. M.— Royal Marines; Royal Mail.
R. M. S.— Railway Mail Service; Royal Mail Service; Royal Mail Steamer.
R. N.— Royal Navy.
R. N. R.— Royal Naval Reserve.

Zech.—Zechariah.
Zeph.—Zephaniah.
Zool.—Zoology.

Abbreviators, a body of 72 writers in the Papal Chancery who have charge of sketching and putting in shape papal bulls, briefs, and consistorial decrees, and signing them in the name of the Cardinal Vice-Chancellor. This body receives its name from the fact of their taking short-hand notes of the decisions to be later expanded. They have existed at least since 1400.

Abd-er-Rahman I., äbd-er-rä'man, founder of the Moorish emirate (later caliphate) of Cordova (q.v.): b. Damascus, 731; d. 788. He was a grandson of the Ommiad caliph Hishám, and having fled to Africa escaped the frightful massacre of his family (see OMMIADS and ABBASSIDES) by Abu 'l-Abbas; a hunted fugitive in the desert, but faithfully protected by the tribesmen, who respected his blood and pitied his misfortunes. Meanwhile Spain was seething with anarchy; each new caliph sent a new emir there; the governor of Africa claimed the right to interfere on the ground that the African governors had captured it; the native chiefs were unwilling to submit to a constant succession of interlopers with no interest but their own, and at last the situation became so intolerable that the Spanish Arabs determined to choose a ruler with his residence in Spain. They selected the wandering heir of the overthrown house, and seeking him out in Africa offered him the place. He landed in Spain 25 Sept. 755, and fixed his royal seat at Cordova. His reign was one of incessant warfare. Hosein ben-Yahva, the Abbasside emir, driven from Spain, fled to Charlemagne and implored his assistance; it was granted and Hosein was re-enthroned at Saragossa, but while the Frankish army was returning through the Pyrenees, the Basque mountaineers fell upon the rear-guard and annihilated it in the pass of Roncesvalles, with its commander Roland. Saragossa was taken after two years' siege, Hosein put to death as a rebel, and Spain to the Pyrenees subdued. A formidable rising in 786 was crushed, and Abd-er-Rahman had two years of life to devote to the arts of peace and the building of his famous mosque at Cordova (now used as a cathedral), with its rows of cupolas supported by 850 pillars of jasper.

Abd-er-Rahman III., the greatest of the caliphs of Cordova, and the first under whom the emirate assumed the title of caliphate: b. 891, acceded 912; d. 961. Measured by what he found and what he left, he must be counted among the ablest rulers of history. The former was a throne to which most of the provincial governors had thrown off allegiance, and the rest rendered such obedience as suited them; a country in a state of permanent anarchy and civil war, perishing of racial, religious, and factional quarrels between Arabs and Moors; the Fatimite dynasty establishing a great empire in Africa, and looking for a speedy succession to the heritage of Spain; on the north, the new Christian states rapidly growing,—Alfonso III. had recently moved his capital across the mountains to Leon, and Sancho had founded the kingdom of Navarre,— so that what escaped the Africans would probably fall into the hands of the Christians. Abd-er-Rahman first put down the worst internal revolt, that of the family of the old brigand Omar ben Hafsun, whose stronghold in the mountains of Andalusia had become a centre for all the renegades, Christians, and rebels of the south. He tied the hands of the Fatimites by subsidizing the native princes who held out against them. The northern danger was the worst. Ordono II. in 914 raided the territory of Merida; and though Merida had thrown off allegiance to Cordova, Abd-er-Rahman wished the more to show them that he was their protector. Collecting and equipping a splendid army, in 918 he gained a great victory over the combined forces of Leon and Navarre, following it up with several campaigns in which he penetrated to Pamplona, the capital of Navarre. These victories were not final: his fortunes were checkered on the Christian side, and he suffered some defeats. But his suzerainty over Navarre was recognized, and in 960 a deposed king was reseated on the throne of Leon by Abd-er-Rahman's troops. Internally his success and glory were unqualified. At his death he left a consolidated kingdom, a full treasury in place of an empty one, internal order kept by a vigilant police, flourishing agriculture based on scientific irrigation, prosperous industries, commerce whose customs dues furnished the majority of the revenue, an income of which one-third paid the current expenses and another third was used for building, and the rest kept for a reserve, the best army in Europe, a superb navy which made him lord of the gates of the Mediterranean, and equality in diplomatic rank with the proudest sovereigns of the world.

Abd-er-Rahman, Saracen chieftain who led an army of nearly 90,000 into Gaul, and was defeated and slain near Poitiers (usually known as the battle of Tours) by Charles Martel (q.v.).

Abd-er-Rahman. See ABD-UR-RAHMAN.

Abdication, in strictness, the renunciation of any office by the holder before the expiration of its term; in actual use, applied only to sovereign rulers, *de jure* or *de facto,* who resign the crown in their lifetimes. The motives for this are as various as human fate, character, policy, or necessity, or the events of history. It may be compulsory — in which case it is really not abdication but deposition — or voluntary. Compulsion may come from foreign conquest; from foreign commands when the king is a puppet, as with the later Polish kings, or Napoleon's shifting his brothers from throne to throne; from the commands of *de facto* controllers of the state within, as with the puppet Roman emperors under the barbarian commanders-in-chief of the army; or from popular or factional insurrections. If voluntary, it may be from desire to let a constitutional machine have a fair chance to work alone, as with Sulla and Diocletian; from satiety with royal power and weariness of royal burdens, as with Murad II. of Turkey; from physical ailments and discouragement, as with the Emperor Charles V.; from penitence and desire to live a religious life, as with more than one mediæval prince who furnished real models for Shakespeare's usurper in ‹As You Like It›; from weariness of the restraints of royal etiquette, as with Christina of Sweden,— perhaps also sincere conversion to Catholicism and unwillingness to enforce a Protestant establishment; from unwillingness to obey an overlord to the harm of his kingdom, as with Louis Bona-

parte; from inability to face the results of crushing defeat, as with Charles Albert of Sardinia; from acceding to a higher throne, as with Charles of Naples; from shame at the results of a bad policy, as with William I. of the Netherlands; from unwillingness to retain a throne against the popular will, as with Louis Philippe — for his resignation was not enforced; or other reasons. In monarchies as a whole, the sovereign can abdicate at will; in England, only by consent of Parliament — which however, as in the case of James II., can assume an implied abdication which the monarch had no intention of executing, the term being a euphemism for deposition.

The following is a list of some of the chief historical abdications, with their dates:

Sulla the Dictator	B.C. 79
Diocletian the Emperor	A.D. 305
Benedict IX, Pope	1048
Stephen II of Hungary	1141
Ladislas III, Duke of Poland	1167
Albert the Bear of Brandenburg	1169
John Balliol of Scotland	1296
Joannes Cantacuzenos, Emperor of the East	1355
John XXIII, Pope	1415
Eric VII of Denmark and XIII of Sweden	1439
Murad II, Ottoman Emperor	1444 and 1445
Charles V, Emperor	25 Oct. 1555
Christina of Sweden	1654
John Casimir of Poland	1668
James II of England	1688
Frederick Augustus of Poland	1706
Philip V of Spain	1724
Victor Amadeus II of Sardinia	1730
Ahmed III, Ottoman Emperor	1730
Charles of Naples (on accession to throne of Spain)	1759
Stanislaus II of Poland	1795
Charles Emanuel IV of Sardinia	4 June 1802
Charles IV of Spain	19 March 1808
Joseph Bonaparte of Naples (transferred to Spain by Napoleon)	6 June 1808
Gustavus IV of Sweden	29 March 1809
Louis Bonaparte of Holland	2 July 1810
Napoleon I of France	4 April 1814 and 22 June 1815
Victor Emanuel of Sardinia	13 March 1821
Charles X of France	2 Aug. 1830
Pedro of Brazil	7 April 1831
(Also abdicated the throne of Portugal in favor of his daughter, at once on his accession in 1826.)	
Miguel of Portugal	26 May 1834
William I of Holland	1 Oct. 1840
Louis Philippe of France	24 Feb. 1848
Louis Charles of Bavaria	21 March 1848
Ferdinand of Austria	2 Dec. 1848
Charles Albert of Sardinia	22 March 1849
Leopold II of Tuscany	21 July 1859
Isabella II of Spain	25 June 1870
Amadeus I of Spain	11 Feb. 1873
Abd-ul-Aziz, Sultan of Turkey	30 May 1876
Pedro II of Brazil	15 Nov. 1888
Milan of Servia	6 March, 1889

Abdiel, ăb'dĭ-ĕl («servant of God»), the one loyal seraph in heaven, according to ‹Paradise Lost,› «among the faithless, faithful only he,» who withstands Satan when the latter is inciting revolt against God for promoting his Son over the heads of the angel peers. Milton took the name from the Jewish cabalists.

Abdomen, ăb-dō'mĕn, in human anatomy, that portion of the body bounded above by the diaphragm, below by the pelvis, behind by the lumbar vertebræ, and in front by a thin layer of muscles, the abdominal muscles. This cavity contains the chief organs of digestion and the genito-urinary system. By reason of the movements of the diaphragm it is rhythmically changing its size, and the movements of the intestines somewhat modify its internal contour. For purposes of description and for localization the abdomen is divided by a tit-tat-toe figure into nine regions; the upper and lower horizontal lines passing at the lower level of the ribs and the upper borders of the pelvis. From above downward the middle squares are termed the epigastric, the umbilical, and hypogastric; to the sides of the epigastric regions are the right and left hypochondrium (under the ribs); the right and left lumbar flank the central umbilical region, and the right and left iliac regions lie down in the pelvis on either side of the hypogastric area. The general location of the abdominal viscera in the various areas is of interest. The liver lies up under the ribs in the right hypochondrium, stretching over the upper part of the epigastrium into the left hypochondrium; the stomach lies mostly in the left hypochondrium and reaches into the epigastrium just below the sternum; the large intestine starts in the right iliac region, the appendix being there also, goes up the right lumbar into the lower portion of the right hypochondrium, crosses straight over, dipping slightly into the umbilical region, from the left hypochondrium it descends into the left iliac region and then turns back into the centre and ends at the rectum. The small intestine occupies most of the umbilical region, extending out into the others. The pancreas lies just behind the lower end of the stomach in the epigastrium. The spleen lies higher up on the left side behind, resting on the 10th and 11th ribs. The kidneys are behind high up, in the hypochondriac lumbar region, just coming below the free borders of the ribs; most pains in the small of the back thought to be kidney pains are pains from constipated bowels; kidney pains are high up under the ribs behind. The genital organs lie in the hypogastric and right and left iliac regions, the bladder low in front in the centre, the uterus slightly above in the centre, the ovaries to the right and left in the right and left iliac fossæ.

In entomology, the whole body of an insect behind the thorax. It usually consists of rings or short hollow cylinders, which are united by a joint or membrane, and in some cases, as in the grub of the chameleon fly, slide upon one another like the tubes of a telescope. Sometimes it bears a sting or an ovipositor, though in the perfect insect no appendages are found.

An abdominal ring is one of two oblong tendinous openings or «rings» existing in either groin, or in the right and left inguinal regions. Through these rings pass the spermatic cord in the one sex, and the circular ligament of the uterus in the other. It is through these rings that inguinal hernia, or rupture, occurs.

Abduction, the act of abducing or abducting; a taking or drawing away, and specifically an unlawful taking. In the United States the word abduction is ordinarily applied to the illegal seizure and detention of a female for the purpose of concubinage, prostitution, or marriage. The punishment for abduction varies in the different States of the Union. The punishment in the United States is lighter than it is in England for this offense. For instance, in New York the crime is punishable by imprisonment for not more than five years, or by a fine of not more than $1,000, or by both.

In common and English law this offense is of three kinds: (1) If any person shall maliciously, either by force or fraud, lead, or take

away, or detain, any child under the age of 10 years, with intent to deprive the parents or other persons having the lawful charge of such child, or with intent to steal any article on its person; or shall receive or harbor such child, knowing the same to have been so stolen or enticed,— every such offender shall be guilty of felony, and shall be liable to penal servitude for not more than seven or less than three years, or imprisoned, with or without hard labor, for any term not more than two years. (2) If the girl is under the age of 16 years, the offender shall be guilty of misdemeanor, and being convicted thereof shall be liable to suffer such punishment, by fine or imprisonment, or both, as the court shall award. (3) If any person shall, from motives of lucre, take away or detain against her will, any woman having any interest, present or future, in any real or personal estate, with intent to marry or defile her, or to cause her to be married or defiled by any other person, every such offender, and every person counseling, aiding, or abetting such offender, shall be guilty of felony, and liable to penal servitude for life, or for any time not less than three years, or to be imprisoned, with or without hard labor, for any term not exceeding five years. If the woman first consent to be taken away, and afterward refuse to continue with the offender, and he forcibly detain her; or if she be forcibly taken away and she afterward consent to her marriage or defilement; or if she be taken away with her own consent, obtained by fraud or imposition, the offense is the same. But if a man, without fraud, deceit, or violence, marries a woman under age, without the consent of her father or guardian, that act is not indictable at common law.

In logic, abduction is a form of reasoning in which the greater extreme is contained in the medium; but the medium is not so evidently in the lesser extreme. Example: « Whatever God has revealed is certainly true; now God has revealed a future retribution; therefore a future retribution is certainly true.» In the use of this kind of reasoning the minor proposition must be proved to be contained in the major.

Abductor, a muscle, the office of which is to draw a limb or portion of a limb to which it is attached away from the centre of that limb. Abductor of the thigh, for example, raises the thigh away from the centre of the body.

In law, a person guilty of abduction.

Abd-ul-Akhad-Khan, ābd-ool-äĸ-äd'ĸan, amir of Bokhara: b. 1852; succeeded his father Muzaffar 12 Nov. 1885, and without trying to throw off Russian suzerainty abolished slavery and underground prisons, reduced the army, regulated taxes, and proved himself an able and progressive ruler.

Abd-ul-Aziz, äbd-ool-a-zēz', 32d Sultan of the Ottoman Turks: b. 9 Feb. 1830; succeeded his brother Abd-ul-Medjid (q.v.), 25 June 1861; d. 4 June 1876. At first he showed himself liberal-minded and open to Western ideas, and promised economy and reform. But ere long he began to spend vast sums on his army, the embellishment of his capital, hunting, and costly journeys. Despite this, reforms were long hoped for, especially after his visit to western Europe in 1867. His government had great difficulties to contend with in the Cretan insurrection of 1866, the struggle of Rumania and Servia for full autonomy, and finally the outbreak of Mohammedan fanaticism. In 1871 the Sultan strove to get the succession settled upon his son, instead of his nephew Murad according to Turkish custom. He next tried to set Russia against the other powers, and plunged ever into deeper financial difficulties, while his stupid misgovernment alienated the provinces and led in 1875 to risings in Bosnia, Herzegovina, and Bulgaria. At last a conspiracy forced him to dismiss his ministers, and next to abdicate the throne, 30 May 1876. Four days later he was found dead. He was succeeded by his nephew Mehemet Murad, who was shortly deposed on the ground of alleged insanity, in favor of the present Sultan, Abd-ul-Hamid, and murdered.

Abd-ul-Hamid, I., äbd-ool-hä-mid', Sultan of Turkey, son of Ahmed III.: b. 1725; succeeded his brother Mustapha III., 1774; d. 1789. He was involved in two wars with Russia, and the treaty of Kutchuk-Kainardji in 1774 compelled him to relinquish the Crimea and other districts; and in 1788 Ochakov, in the Kherson district, was taken by the Russians.

Abd-ul-Hamid II., 34th Sultan of the Ottoman Turks: b. 22 Sept. 1842, second son of Abd-ul-Medjid; acceded 1876 on the deposition of his brother Murad V. At this time the insurrection of Bosnia and Herzegovina was in full blaze, and the intolerable misgovernment in Bulgaria by the local zaptiehs and others was preparing that province to follow suit — the desire of the people for security of life, property, and female honor being of course accredited to « Russian intrigues,» no other cause being adequate. Internally, the « Young Turkey » party, headed by Midhat Pasha — which wished to free Turkey from its European leading-strings, but by honest reforms and a parliamentary system — were equally obnoxious to him as reformers and as revolutionists. The storm of Oriental butchery and outrage he turned loose on a Bulgarian district (see BATAK) roused the Russians to a frenzy of rightful horror which forced the hand of the Czar, who did not wish war; and in the conflict of 1877–8 the Russian armies advanced almost to Constantinople. Christian Europe would perhaps have been nearly freed from the Turkish incubus, which has blighted every land it has rested on, but that the great powers flamed out in jealousy of Russia: the English Tories were barely restrained from making war on her and leaving Turkish power over the provinces just as it was, by the Liberal uprising headed by Mr. Gladstone. Even the Treaty of San Stefano (q.v.), which Russia exacted from Turkey, was not allowed to stand, the Berlin Congress (q.v.) cutting down the Turkish sacrifices; even so, however, Servia, Rumania, and Montenegro were freed altogether from Turkish suzerainty, Bosnia and Herzegovina were handed over to Austria, and Bulgaria was left in only nominal dependence, though by a futile contrivance divided into two provinces which shortly reunited; a small part of Armenia was also ceded to Russia. The treaty obligated the Sultan to introduce reforms into the remaining Christian provinces, as if the history of the previous half-century had not shown what that meant even with a sincere Sultan; and Abd-ul-Hamid had

no design of paying any attention to it. He was a bigoted Mussulman of the very party which had nullified all the efforts of Mahmud II., Abd-ul-Medjid, and Reshid Pasha, and believed that infidels should have no choice but slavery or the sword, according to the Prophet's word. He set himself at once to recover the fullest autocracy at home and evade the demands of the Christian states abroad. Midhat was shortly arrested, nominally for the acts that had given the Sultan his throne, banished, and died soon and suddenly. All power was centred in the seraglio at Constantinople, wholesale murders and terrorism cowed all opposition, and for many years no whisper of constitutionalism has been heard in Turkey. The European powers were astutely set by the ears to prevent each other from gaining any advantage of it; the Christians were treated worse than ever; finally, in 1895-6 the signal was given to let loose on all Armenia the horrors which in one spot of Bulgaria had cost Turkey half her European possessions less than twenty years before. Abd-ul-Hamid had done his work well: no abler diabolic statesman has existed in our era. Not a power lifted a finger: even the English Liberal ministry, though England had forced Russia to leave Armenia to Turkey by guaranteeing good government for it, raised no hand to protect it. A considerable percentage of the Armenians were exterminated by hordes of savage Kurds and other irregulars, with indescribable details of outrage and torture; and the Sultan found himself raised to such consideration in Europe that he shortly attempted to evade payment of a small Austrian debt, when Count Goluchowski threatened to bombard Smyrna, an effective proceeding which secured a prompt settlement of the debt. In 1897 Crete again rose, and Greece took her part, in the expectation of European help; but the time had gone by. In the ensuing war with Turkey she was not only beaten but disgraced; Europe, however, had the grace not to allow Turkey to resume sovereignty over any Christian land. Shortly after, Abd-ul-Hamid was imprudent enough to let some Englishmen be murdered, and the Powers took Crete from him and gave it a separate government. The basis of his internal power has been his championship of orthodox Mussulmanism: he claims the literal caliphate.

Abdullahi. See KHALIFA, THE.

Abd-ul-Latif, äbd'ool-lä-tēf', eminent Arab writer: b. Bagdad, 1161; d. there 1231. By way of education he committed to memory the Koran, the chief poets, and not a few grammatical treatises. He studied medicine and practised till 1185, when to complete his culture he betook himself to Damascus, where the famous Saladin had gathered round him the most learned men of the time. After the death of Saladin, who had liberally assisted him, he went to Cairo, delivered lectures on medicine and other sciences, and published an excellent description of Egypt, still extant and keeping his fame alive: translated into Latin by White (Oxford 1800), and into French by De Sacy (1810). He died at Bagdad in 1231, on his way to Mecca.

Abd-ul-Medjid, äbd-ool-me-jēd', 31st Sultan of the Ottoman Turks, son of Mahmud II.: b. 23 April or 6 May 1823; acceded 1 July 1839; d. 25 June 1861. He received the usual enfeebling harem education, his father failing in his efforts to rescue his children from the system. On his accession Turkish affairs were critical. The great viceroy of Egypt, Mehemet Ali, had a second time revolted; ten days previously the Turkish admiral had turned traitor and put the entire fleet in his hands; and three days afterward Mehemet's son Ibrahim, the greatest Moslem soldier of the century, had routed the Turkish army at Nizib, and was marching straight on Constantinople, where the orthodox party, enraged at Mahmud's reforms, had conspired to place Mehemet Ali on the throne. But the European powers interfered, and the treaties of 27 Nov. 1840 and July 1841 confined Mehemet to Egypt again. Abd-ul-Medjid at once set about complying with his father's express instructions and carrying out his reforms: 3 Nov. 1839 he promulgated the «Hatti-sherif of Gulhané,» placing all his subjects on full religious and civil equality, and providing for security of life and property to all, with just and equal taxation, administration of laws, and conscription; February 1856, after the Crimean war, it was supplemented by another to the same purport. But the Mussulman aristocracy and the educated classes (Ulema) regarded it as an anti-Mussulman revolution to no profit but that of the infidels, and fought it so furiously that it remained practically inoperative, and rather sharpened the edge of their ill-treatment of the Christians; and repeated conspiracies were formed against his life, whose members however the kindly Sultan would not put to death. His right hand in reform work was the able and humane Reshid Pasha, a Mussulman educated in France: through him the army was reorganized 1843-4; a board of education instituted 1846; a university founded, with military, medical, and agricultural colleges; a hateful capitation tax abolished, slave-trading repressed, and commerce advanced. Nothing can better prove the intrinsic and hopeless rottenness of the Mussulman system under modern conditions than the fact that these measures were written in water and died almost with their birth; their main fruit was bloody insurrections in various parts of the empire, of which the great Syrian massacres of 1860 (see SYRIA) were the worst. In 1849 Abd-ul-Medjid honored himself by boldly refusing to surrender Kossuth and the other Hungarian refugees, after the failure of the Hungarian revolution, at the joint demand of Russia and Austria. For the Crimean war, and its antecedents and results, see that head. In later life he sunk into extravagance and sensuality; but he was essentially a good-hearted and honorable man, powerless against fate. He was succeeded not by one of his seven sons, but by his brother Abd-ul-Aziz, the oldest living member of the house of Othman.

Abd-ur-Rahman, äbd-oor-rä'man, sultan of Fez and Morocco: b. 1778; succeeded his uncle 1823; d. 1859. His first four years of rule were occupied in quelling insurrections. Next, Austria refused to pay the tribute for safety against pirates levied by Morocco on European ships in the Mediterranean: the Sultan wisely adjusted the dispute by relinquishing this blackmail. (See MOROCCO.) The religious war under Abd-el-Kader against the French in Algeria involved Morocco in its movements: the defeat

by the French in 1844 compelled the Sultan to order Abd-el-Kader to quit the country, which, however, he did not for three years longer. The piratical habits of the Moroccans brought him to the brink of war with more than one European State. He was succeeded by his eldest son, Sidi-Mohammed (1859–73).

Abd-ur-Rahman-Khan, äbd-oor-rä'man-hän, amir of Afghanistan, son of Afzul (uf-'zool) Kahn, nephew of the amir Shere Ali, grandson of Dost Mohammed: b. Kabul, 1844; d. 3 Oct. 1901. During the civil war of 1864 in Afghanistan (q.v.) between Dost Mohammed's sons, he played a leading part on his father's side against his uncle, won several battles,— the important victories of Shaikhabad and Khelat-i-Ghilzai were mainly due to his ability,— and for a time his father seemed secure of the amirate; Abd-ur-Rahman was made governor of Balkh, and won great popularity by his moderation and by marrying the daughter of the chief of Badakhshan. In 1868, however, Shere Ali gained the mastery, and the English government helped to put down further resistance for order's sake. Yakub-Khan drove out his cousin Abd-ur-Rahman, who after hunted wanderings reached Russian territory, and Gen. Kaufman allowed him to live at Samarcand with a pension of 25,000 rubles a year. Here he remained till 1879, when Shere Ali's death, and the weakness of Yakub, whom the English had recognized as amir, gave him a chance to return to Balkh, where he was welcomed. The murder of the British Resident at Kabul and Yakub's deposition followed; Abd-ur-Rahman came forward once more, and was acknowledged amir by the principal chiefs and the English government, which gave him a subsidy of £160,000 a year, and large gifts of artillery, rifles, ammunition, etc. In 1893 the Indian government turned over to him Kafiristan, in the Hindu-Kush mountains, and he brought its savage tribes under control in 1896. The English government showed him great honor, as he deserved; and made him G.C.B. and G.C.S.I. He was succeeded by his eldest son, Habibullah-Khan, who had been associated with him in the government for some time.

A Becket, Thomas. See Becket, Thomas Á.

Abeel, David, American missionary: b. New Brunswick, N. J., 12 June 1804: graduated at Rutgers, studied theology, and held a pastorate in Athens, N. Y., 1826–9; resigned from failing health, and went to China, October 1829, as chaplain for the Seamen's Friend Society, and in 1830 for the A. B. C. F. M. He visited Java, Singapore, and Siam, studying Chinese; his health again failing he started for home 1833 by way of Europe, giving addresses on the claims of the heathen in Holland, France, and Switzerland, in England forming a society to promote Eastern women's education, and in America publishing works on similar subjects and his Chinese experiences. In 1839 he revisited Malacca, Borneo, and parts of Asia, and in 1842 established a mission at Amoy. In 1845 his health failed finally, and returning he died in Albany in 1846. He was one of the ablest, most practical, and most successful of early missionaries. See 'Life' by G. R. Williamson (N. Y. 1848).

Abel, John J., American physiological chemist: b. Cleveland, Ohio, 19 May 1857. He was graduated at the University of Michigan in 1883; studying abroad, he took M.D. at the University of Strasburg in 1888. He has devoted himself to the chemistry of the human body, and is professor of pharmacology in Johns Hopkins, as well as in charge of the department of physiological chemistry.

Abelard, ăb-ę-lär (Fr. **Abélard,** ăb-ā-lär), **Pierre,** pē-ār, a distinguished philosopher, and lover of Héloïse. His real name was Pierre de Palais, the other being a nickname spelled in many other ways, but originally Bajolardus, "bacon-licker," from a school joke, which he changed to Habelardus, "bacon-haver," as a retort: b. 1079 near Nantes, in the little village of Pallet, the property of his father Berenger; d. 1142. Full of intellectual enthusiasm, he gave up his patrimony to his younger brothers to devote himself to a life of study. Those studies were very wide, though the usual inclusion of Greek and Hebrew is an error; but his chief passion was philosophy, and its great implement, the scholastic logic, in which he soon became the most eminent master of his age. Having learned all that Brittany could teach him, he went to Paris, the university of which attracted students from all parts of Europe. Guillaume de Champeaux, a follower of Anselm and an extreme Realist, was the most skilful disputant of his time, and Abelard, profiting by his instructions, was often victorious over his master in contests of wit and logical acumen. The friendship of Champeaux was soon succeeded by enmity; and Abelard, who had not yet completed his 22d year, removed to Melun, whither he was soon followed by a multitude of young men, attracted from Paris by his great reputation. Hostility still pursued him, but he left Melun for Corbeil, nearer the capital, where he was still more admired and persecuted. Soon after he ceased teaching to recruit his strength, and after two years returned to Paris and found that his former teacher had removed to a monastery outside the city.

He again joined issue with him and gained so complete a triumph that he opened in Paris a school of rhetoric, the fame of which soon deprived all the others of their pupils. Shortly afterward he was appointed to his rival's chair in the cathedral school of Notre Dame, where he educated many distinguished scholars, among whom were the future Pope Celestin II., Peter of Lombardy, bishop of Paris, Berenger, bishop of Poictiers, and St. Bernard.

At this time there resided close to Notre Dame, a young lady, by name Héloïse, niece to the canon Fulbert, then of the age of 17, and remarkable for her beauty, genius, and varied accomplishments. Abelard became inspired with such violent love for Héloïse as to forget his duty, his lectures, and his fame. Heloïse was no less susceptible. Under the pretext of finishing her education he obtained Fulbert's permission to visit her, and finally became a resident in his house. His conduct in abusing the confidence which had been placed in him opened the eyes of Fulbert. He separated the lovers, but too late. Abelard fled with her to Brittany, where she was delivered of a son, who died early. Abelard now resolved to marry her secretly. Fulbert gave his consent, the marriage

was performed, and in order to keep it secret Héloïse remained with her uncle, while Abelard retained his former lodgings and continued his lectures. Abelard, however, carried her off a second time and placed her in the convent of Argenteuil.

Fulbert erroneously believed it was intended to force her to take the veil, and under the influence of rage subjected Abelard to mutilation. He became, in consequence, a monk in the abbey of St. Denis, and Héloïse took the veil at St. Argenteuil. After time had somewhat moderated his grief he resumed teaching. At the Council of Soissons (1121), no defense being permitted him, his "Essay on the Trinity" was declared heretical, and he was condemned to burn it with his own hands. Continued persecutions obliged him at last to leave the abbey of St. Denis and to retire to a place near Nogent-sur-Seine, where he built a rude hut in which he determined to live a hermit's life. Even here, however, students flocked to him, and they built him an oratory, which he dedicated to the Holy Ghost and hence called Paraclete. Being subsequently appointed abbot of St. Gildas de Ruys, in Brittany, he invited Héloïse and her religious sisterhood, on the dissolution of their monastery at Argenteuil, to reside at the above oratory, and received them there. He lived for some ten years at St. Gildas. Ultimately, however, he fled from it and lived for a time in other parts of Brittany.

St. Bernard, of Clairvaux, the leading opponent of the rationalistic school of Abelard, laid his doctrines before the Council of Sens in 1140, had them condemned by the Pope, and obtained an order for his imprisonment. Abelard appealed to the Pope, publishing his defense, and went to Rome. Passing through Cluny he visited Peter the Venerable, who was abbot there. This humane and enlightened divine effected a reconciliation between him and his enemies, but Abelard resolved to end his days in retirement. The severe penances which he imposed upon himself, together with the grief which never left his heart, gradually consumed his strength, and he died, a pattern of monastic discipline, in 1142, at the abbey of St. Marcel, near Châlons-sur-Saône. Héloïse begged his body and had him buried in the Paraclete, of which she was at that time the abbess, with the view of reposing in death by his side. In 1800 the ashes of both were carried to the Museum of French Monuments at Paris, and in November 1817 were deposited under a chapel within the precincts of the church of Monamy. The small chapel, in the form of a beautiful marble monument, in which the figures of the ill-fated pair are seen reposing side by side, is now one of the most interesting objects in the Parisian cemetery of Père la Chaise.

Abelard was distinguished as a grammarian, orator, logician, poet, musician, philosopher, theologian, and mathematician. As a philosopher he founded an eclectic system commonly but erroneously termed Conceptualism, which lay midway between the prevalent Realism, represented in its most advanced form by William of Champeaux, and extreme Nominalism, represented in the teaching of his other master, Roscellin, and largely approached the Aristotelian philosophy. In ethics Abelard placed much emphasis on the subjective intention, which he held to determine the moral value as well as the moral character of man's action. Along this line his work is notable, owing to the fact that his successors did little in connection with morals, for they did not regard the rules of human conduct as within the field of philosophic discussion. His love and his misfortunes have secured his name from oblivion; and the man whom his own century admired as a profound dialectician is now celebrated as the martyr of love. The letters of Abelard and Héloïse have been often published in the original and in translations. Pope's poetical epistle, 'Eloisa to Abelard,' is founded on them. Abelard's autobiography, entitled 'Historia Calamitatum,' is still extant.

Abercromby, David, Scottish philosopher: d. about 1702. His chief work is entitled 'A Discourse of Wit' (1686). He also wrote many treatises and his work is said to antedate the so-called Scottish School of Philosophy.

Aberdeen, 4TH EARL OF (GEORGE HAMILTON GORDON), British statesman and premier: b. Edinburgh, 28 Jan. 1784; succeeded to title in 1801; d. 14 Dec. 1860. He was educated at Harrow and St. John's College, Cambridge. Shortly after returning from a Continental and Grecian tour, full of classical enthusiasm, he established the Athenian Society; whence Byron's sneer at "the traveled thane, Athenian Aberdeen." He severely criticised Gell in the 'Edinburgh Review,' and wrote an introduction to Wilkins' translation of Vitruvius, published separately in 1822 as 'An Inquiry into the Principles of Beauty in Athenian Architecture.' In 1806 he entered Parliament as a Scotch representative peer, and was twice re-elected. In 1813 he was sent to Austria to bring it into the coalition against Napoleon, and in 1814 was a signatory of the Treaty of Prague; he won credit in diplomacy, and the same year was made Viscount Gordon in the British peerage. During 1815–28 he devoted himself to his estates. In 1828 he became chancellor of the Duchy of Lancaster, and a few months later foreign secretary in Wellington's Cabinet, and had the satisfaction of seeing Greek independence recognized. He warmly supported repeal of the test and corporation acts, and Catholic emancipation. Peel had him in both his Cabinets, 1834–5 as colonial secretary, 1841–6 as foreign secretary. In 1846, during the struggle which rent the Established Church of Scotland in twain, he brought in a compromise bill which was denounced by both halves; and after the Disruption in 1843 again attempted conciliatory measures without result. On Peel's death in 1850 he became the leader of the free-trade Conservatives. The Derby administration being unable to stand, Lord Aberdeen in 1853 formed a coalition ministry. For a time it was very popular; unluckily the Crimean war supervened. Aberdeen's tardiness of action and reluctance to enter on hostilities, the result of a constitutional aversion to war, irritated the country, which was in one of its periodical anti-Russian frenzies, and bent on fighting. Moreover, the early portion of the war was shockingly mismanaged, as those of commercial countries always are; and on the appointment of a committee of inquiry, the ministry, which had uniformly resisted the motion, resigned, and Palmerston's succeeded it. This closed Aberdeen's public

life. His dislike to "spirited" foreign policies and interference with other countries, and his sympathy with the Holy Alliance, gave him the name of an enemy to liberty; but the above detail shows its injustice.

Aberdeen, Miss., city and seat of Monroe county; on the Tombigbee River, and the Illinois Cent., the Kansas City, M. & B., and the Mobile & O. R.R.'s; 130 m. S.E. of Memphis, Tenn. Its chief trade and manufacture are cotton and cotton products, lumber coming next. Pop. (1900) 3,434.

Aberdeen, S. D., seat of Brown County, on the Chicago & N. W., Chicago, M. & St. P., and Great Northern R.R.'s; settled 1880, inc. 1882; 280 m. W. of Minneapolis, 125 m. N.E. of Pierre. It is the farming and lumber trade centre of a large section; manufactures boots and shoes, flour and feed, soap, plows, machinery, etc., and has 10 grain elevators, granite and marble works and creameries. Its factories are supplied with abundant water power furnished by artesian wells. It has national banks, several daily, weekly, and monthly periodicals, a system of graded public schools, free library, and an assessed property valuation of about $1,500,000. The mayor and city council, coöperating in most appointments, are elected biennially. Pop. (1900) 4,087; (1903) 5,572.

Ab'erdeen, the chief city and seaport in N. Scotland, fourth largest in all Scotland; lies in Aberdeenshire, 111 miles N. of Edinburgh. William the Lion gave it a charter in 1179; the English burned it in 1336, but it was soon rebuilt; within the same parliamentary boundary is a small town a mile N. near the Don mouth, the seat of St. Machar's Cathedral (1357–1527), now represented by the granite nave, which, as restored since 1869, is used as a parish church. King's College and University, founded by Bishop Elphinstone in Old Aberdeen in 1494, and Marischal College and University, founded by the Earl Marischal in New Aberdeen in 1593, were in 1860 united into one institution, the University of Aberdeen. It has 23 professors and from 800 to 900 students in its four faculties of arts, divinity, law, and medicine. The students are divided into four "nations," Mar, Buchan, Moray, and Angus. There is a lord rector, chancellor, vice-chancellor, and two secretaries. With Glasgow University, it sends one member to Parliament. Marischal College was rebuilt in 1841. King's College is a stately fabric dating from 1500, its chapel adorned with exquisite wood-carvings. In the 17th century Aberdeen had become an important place, but it suffered much from both parties in the civil wars. It has a flourishing trade and thriving manufactures; and having been largely rebuilt and extended since the formation of Union Street in 1800, the "Granite City" now offers a handsome and regular aspect. Among the chief public edifices are the county buildings, the post-office, the Market Hall, the Trades Hall, the Royal Infirmary, the lunatic asylum, the grammar school, the art gallery and art school, and Gordon's College. The last has been much extended as a technical school, the foundationers being no longer resident; while the infirmary was reconstructed and modernized to celebrate the Queen's Jubilee (1887). Of more than 60 places of worship the only one of much interest is the ancient church of St. Nicholas, now divided into the East and West churches, and having an imposing spire 190 feet high. A fine carillon of 37 bells was placed here in 1887. One may also notice the market-cross (1686), the Wallace, Gordon Pasha, and three other statues, and the Duthie public park of 47 acres. It has a large trade from the port, and good railway facilities. The chief exports are woolens, linens, cotton yarns, paper, combs, granite (hewn and polished), cattle, grain, preserved provisions, and fish. Aberdeen has the largest comb and granite-polishing works in the kingdom. There are also several large paper works near by. Wooden ship-building was formerly a prosperous industry, the Aberdeen clipper-bow ships being celebrated as fast sailers, but since 1860 they have been gradually superseded by iron or steel steamships; and, owing to its remoteness from coal and iron, its ship-building now is greatly contracted. Pop. of parliamentary borough (1891) 121,623; (1901) 153,108; 9,386 in Kincardineshire.

Aberdeen University, See ABERDEEN (Scotland).

Abernethy, John, Irish dissenting clergyman and pioneer of toleration: b. Coleraine, 19 Oct. 1680; d. 1740. The son of a Nonconformist minister, he graduated successively from Glasgow and Edinburgh universities, was licensed to preach before coming of age, urged to take an important charge in Antrim at 21, and two years later was ordained there. The work he did there for many years was of the most remarkable kind, in drafts on body, brain, soul, and will; and he was eminent in all. In 1717 he was invited at once to Dublin and Belfast; the Synod assigned him to Dublin; he refused to leave Antrim and was considered a Church mutineer; a furious quarrel followed, developing into the fight in the Irish Presbyterian Church between "subscribers" and "non-subscribers" (Abernethy's party), the latter being formally barred out in 1726. The real question at issue was of old orthodoxy versus the liberalizing opinions which he disclaimed holding, but which have of course long since left his position far behind. In 1730 he was nevertheless called to Dublin. The next year came up the question of the Test Act, really involving the whole subject of religious tests in civil life; and Abernethy took a firm stand against "all laws that, upon account of mere differences of religious opinion and forms of worship, excluded men of integrity and ability from serving their country," asserting near a century ahead of his time that a Roman Catholic could be such. His 'Tracts' were later collected, and did good service in the Catholic Emancipation fight of the next century. Abernethy was the bravest of the brave, not only in advocating unpopular truths to his own harm, but in resisting the highest dignitaries in the cause of right. See 'Diary,' 6 vols.; Duchal's 'Life'; 'History of Irish Presbyterian Church.'

Abernethy, John, the great English surgeon, grandson of the preceding: b. London, 3 April 1764; d. 20 April 1831. Educated at Wolverhampton grammar school, he was apprenticed at 15 to Sir Charles Blicke, a leading London surgeon, assistant surgeon at St. Bartholomew's Hospital; he also attended the lectures of Pott, the chief surgeon there, of John Hunter, and the anatomical lectures at London Hospital of Sir William Blizzard, who early employed him as

demonstrator. Pott, resigning, Blicke took his place, and made Abernethy assistant surgeon in 1787. His lectures drew such crowds that a special building was erected, now the celebrated St. Bartholomew's School. In 1813 he was appointed surgeon to Christ's Hospital, in 1814 professor of anatomy and surgery to the College of Surgeons, and in 1815 full surgeon to St. Bartholomew's, a post which he resigned in 1829. Of his numerous medical works the most important is 'Surgical Observations on the Constitutional Origin and Treatment of Local Diseases,' which, from his frequent references to it, became known as 'My Book.' He was one of the first to prove that topical symptoms should be treated by general remedies, especially for the stomach and bowels; and he was a persuasive and influential teacher, though over-dogmatic. He was the first to introduce the capital surgical improvement of tying the great arteries in operations for aneurism, etc. See 'Works,' 5 vols. 1820; 'Memoirs' by Macilwain, 1853, not highly esteemed.

Aberration. In physics, (1) that property of a lens or curved mirror in virtue of which it does not form a sharp, flat image devoid of false color fringes. Spherical aberration is the geometrical distortion of the image due to the fact that the surface of the lens or mirror is spherical instead of having the theoretically best form. It is easy to grind a spherical surface, and more difficult to grind those of other forms; hence in the practical manufacture of a high-grade lens the curvatures are carefully calculated, so that spherical surfaces may be used, while the spherical aberration is still kept within limits that are consistent with the use of the lens. (See LENS.) Chromatic aberration is the defect in virtue of which the focal length of the lens is not the same for all colors. A lens possessing chromatic aberration gives an image that is blurred with rainbow-like fringes; one that is devoid of chromatic aberration is said to be achromatic (see LIGHT). Mirrors, whether concave or convex, have no chromatic aberration.

(2) The slight displacement of the apparent position of a star or other celestial object, due to the fact that although the velocity of light is very great it is not infinite. In recent years much attention has been paid to aberration phenomena, because the observed amount of the displacement of a star indicates that the ether of space is stationary and that the earth passes through it like a fish through stagnant water; while direct experiments indicate, on the contrary, that the ether is dragged along with the earth to a considerable extent. See ETHER.

Ab'ert, John James, American military engineer: b. Shepherdstown, Va., 17 Sept. 1788; d. 1863. He graduated at West Point in 1811, and at once went into the War Office; was admitted to the bar; served in the War of 1812, becoming topographical engineer with the rank of major; was made chief and colonel of topographical engineers in 1838, and assisted in developing important canals and other works. His engineering reports are standard, and he was a founder of the National Institute of Science, since merged in the Smithsonian.

Abeyance, meaning expectancy; probably derived from the French *bayer*, to gape after. When real or personal properties are in expectation, or the intendment of the law, they are said to be in abeyance, or not actually possessed. The word is often used in the Church of England, a living being known as "in abeyance" when it is left vacant owing to the unwillingness of the patron to declare himself in favor of any particular applicant for the office.

Abich, Wilhelm Herman, German mineralogist and naturalist: b. Berlin 11 Dec. 1806; d. Graz 2 July 1886. After completing a course of study in the natural sciences at the University of Berlin, he traveled in Italy and Sicily. In 1842 he was appointed to the chair of mineralogy in the university at Dorpat, and in 1853 was elected a member of the Academy of Sciences in Saint Petersburg, for whom he wrote exhaustive reports of the explorations which he had made in the Caucasus, Russian Armenia and northern Persia. He also published several books descriptive of the minerals found in the different countries in which he had traveled, the most important of which are: 'Erläuternde Abbildungen von geologischen Erscheinungen, beobachtet am Vesuv und Aetna 1833 und 1834' (1837); 'Ueber die Natur und den Zusammenhang der vulkanischen Bildungen' (1841); 'Ueber die geologische Natur des armenischen Hochlander' (1843); 'Ueber die Natronseen auf der Araxesebeni' (1846–9); 'Vergleichende geologische Grundzüge der kaukas-armenischen und nordpersischen Gebirge' (1858); 'Sur la Structure et la Géologie du Daghestan' (1862).

Abildgaard, ä'bĭl-gôrd, **Nikolai Abraham,** Danish painter: b. Copenhagen 4 Sept. 1744; d. Frederiksdal 4 June 1809. He studied for some time at the academy in Copenhagen, but in 1772 went to Rome to study under the masters. After his return he was appointed to a professorship at the academy in 1786, and in 1789 was elected a director. The greater number of his paintings were of an historical nature and he had much to do with the founding of the Danish school of historical painting. A series of 10 pictures in the castle of Christiansborg, which burned in 1794, and scenes from Shakespeare and Ossian were his most important works.

Abilene, Kan., city, seat of Dickinson County, 163 m. W. of Kansas City, on the Kansas River and three railroads: Union Pacific, Chicago, R. I. & P., and Atchison, T. & S. F. R.R.'s; settled 1856, incorporated 1869, the original charter being still in force. For many years it has been one of the great agricultural market centres of the State, the focus of a large farm loan business, and the sales-ground for the large droves of cattle that are annually brought from Texas. It has also large manufacturing interests, including several flour-mills and creameries, as well as manufactures of iron bridges, carriages, etc. Mineral water from adjacent sand springs is bottled for export. The government consists of a mayor and council. Pop. (1900) 3,507.

Abilene, Tex., city, seat of Taylor County, 160 m. W. by S. of Fort Worth, on the Texas & P. R.R. The centre of a farming, cotton, and stock-raising district, its chief interests lie in its cotton-gins, flour- and feed-mills and grain elevators, although it also has flourishing manufactories of saddlery, harness, lumber, and ice. Its educational advantages are excellent, and

include a public high school and a prosperous Baptist college. Pop. (1900) 3,411.

Abingdon, Ill., city, Knox County; 85 m. N.E. of Quincy; on the Chicago, B. & Q. and the Iowa C. R.R.'s. Settled 1828, incorporated 1857, now acting under charter of 1859. Among its many industrial interests, which include wagon-works, saw-mills, and manufactories of gloves and organs, it has the largest animal-trap factory in the world. Besides its excellent school system, it is the seat of Hedding College (M. E.) and Abingdon (Christian) College, the latter having been founded in 1855. A mayor and council of five is annually elected. Pop. (1900) 2,022.

Abingdon, Va., post village, seat of Washington County; on the Norfolk & W. R.R., 315 m. S.W. of Richmond and 140 m. W. by S. of Lynchburg. Settled 1730, incorporated 1788, it has long been noted for its large tobacco and live-stock interests, as well as for its valuable deposits of iron, gypsum, and salt, much of the salt used in the Southern States during the Civil War having been obtained in this vicinity. Its manufactures include wagon-works and planing-mills, besides cigar, tobacco, and pipe factories. It is also the seat of Martha Washington College for girls, the Stonewall Jackson Female Institute, the Academy of the Visitation, and Abingdon Academy for boys. Pop. (1900) 1,306.

Abington, Mass., a post township in Plymouth County, 20 m. S.E. of Boston, on the Old Colony division of the New York, N. H. & H. R. R.R. Settled in 1680, incorporated 1712. Its southern portion is now known as Whitman; its northern portion as North Abington, and both are important manufacturing centres, the chief industries being the making of machinery, shoes, and leather goods. The government is by town meeting. Pop. (1900) 4,489.

Abiogenesis. See BIOGENESIS.

Abjuration, the act of forswearing, abjuring, or renouncing upon oath; a denial upon oath; a renunciation upon oath. Chiefly a law term and used in the following senses:

1. In the United States when an alien wishes to become a citizen he must declare among other things, that he doth absolutely and entirely renounce and *abjure* all allegiance and fidelity which he owes to any foreign sovereign, etc., and especially, by name the sovereign, etc., whereof he was before a citizen or subject.

2. An abjuration of the realm. During the Middle Ages the right of sanctuary was conceded to criminals. A person fleeing to a church or churchyard might permanently escape trial if, after confessing himself guilty before the coroner, he took an oath abjuring the kingdom: promising to embark, at an assigned port, for a foreign land, and never to return unless by the king's permission. By this, however, he forfeited his goods and chattels.

3. Special. An abjuration or renunciation of all imagined allegiance to the Jacobite line of rulers, after the English nation had given its verdict in favor of William and Mary.

The oath of abjuration was fixed by 13 Wm. III. c. 16. By the 21 & 22 Vict. c. 48, one form of oath was substituted for the oaths of allegiance, supremacy, and abjuration. For this form another was substituted by the Act 30 & 31 Vict. c. 75, § 5. This has in turn been superseded by the Promissory Oaths Act, 31 & 32 Vict. c. 72.

4. An abjuration, renunciation, or retraction of real or imagined heresy or false doctrine. Thus the now abolished 25 Chas. II. c. 2, enacted that certain tenets of the Church of Rome were to be solemnly renounced.

Ablution, or the ceremonial act of washing to symbolize purification from uncleanness, is a rite which has been observed by many races of people from the early Mosaic days down to our own time. Under the Mosaical dispensation the act of ablution had four purposes: (1) To cleanse from the taint of an inferior position before initiation into a higher state, as when Aaron and his sons, having been chosen for the priesthood, were washed with water before they were invested with their robes of office; (2) to cleanse in order to fit one for special acts of religious ceremony, as when the priests were required, under the penalty of death, to wash both their hands and feet before approaching the altar; (3) to cleanse from defilement contracted by some particular circumstance which prevented one from enjoying the privileges of ordinary life, of which there were no less than 11 species of uncleanness recognized by the law; and (4) to cleanse or absolve oneself from the guilt of a particular act, as when, in expiation for an unknown murder, the elders of the village washed their hands over the slaughtered heifer, saying, "Our hands have not shed this blood, neither have our eyes seen it" (Deut. xxi.). This practice was also common both among the Greeks and Romans, and it was undoubtedly in accordance with this practice that Pilate called for water and washed his hands to signify that he held himself innocent of the blood of Jesus Christ (Matt. xxvii. 24).

Ablution by the priests before the performance of sacred ceremonies was common even among the heathen, while the Egyptian priests carried the practice to such an extreme that they shaved their entire bodies every third day and then washed themselves in cold water twice every day and twice each night, that no particle of filth might even rest upon them. Such an act corresponds somewhat to the more simple *wadu* of the Mohammedans, a ceremonial washing which they are compelled to observe five times daily, or immediately before their stated prayers, and these do not begin to represent the formal acts of cleansing required by the Moslem law. For example, the ablution for positive defilement required by Moses has its counterpart in the Mohammedan *ghual*, and yet again, under the Moslem law, the causes of such defilement are specified so minutely that they greatly exceed those of the ancient Jews. So strict was the law upon this point, however, that, when water could not be obtained, it was required that the purification should be made with something that might represent the water. In times of drought, therefore, or on occasions of sickness, the act of purification might be performed by rinsing, or rubbing the hands and face with dry sand. This form of cleansing was called *tayemmum*.

The ceremony of ablution at communion was adopted by the early Christian Church, and has been retained both in the Eastern and Roman

Catholic Churches. In the Roman Catholic Church it has become a liturgical term, denoting the two acts of cleansing performed during the mass: (1) When wine is poured into the chalice to disengage any particles which may be left in the vessel; and (2) when both wine and water are poured over the priest's fingers into the chalice. In the Greek Church the word "ablution" is applied to a ceremony performed seven days after baptism, when the unction of the chrism is formally washed off from those who have been baptized.

Abnormal Psychology covers all considerable deviations from the typical normal mind. Normal minds like normal bodies differ much among themselves; it is therefore impossible to lay down any arbitrary rule by which variations from a type or "norm" — at least, if the variation be but slight — may be identified. A pulse rate which, in a young child, indicates health, may, in an adult, be a symptom of disease; a pallid skin which is "normal" to one individual may, in another, proceed from a deranged circulation. Similarly, emotional excitement which, for a person of sanguine temperament, is entirely "natural," may, if found in a phlegmatic individual, express a highly abnormal mental state; and what is unhesitatingly pronounced insanity in one person may, in another, be laid to eccentricity. Abnormality must, therefore, be taken as a deviation, not from a general normal type, but from a particular standard which a given class of individuals represents. Abnormal psychology is a wider term than "mental pathology" or "mental disease." It is wider because many abnormalities of mind occur in a perfectly healthy — nonpathological — condition. Deaf-mutism, for example, is no more pathological than the having of supernumerary toes and fingers. Abnormal psychology falls into three parts; the first deals with temporary derangements, the second with more or less permanent derangements (mental diseases, including insanity), and the third with defective and exceptional minds.

1. Under temporary derangements are to be classed abnormal illusions, hallucinations, dreams, and hypnosis. All these derangements indicate a loss of efficient mental functioning without, however, necessarily entailing a permanent morbid condition. In order to understand the significance of such deficiencies it will be necessary to keep in mind the more important functions which devolve upon consciousness. These are (1) perception, the correct apprehension of the external world of objects and events, (2) the appropriate reaction of the individual upon objects (for example, instinctive, impulsive, and volitional actions), and (3) the establishment and maintenance of adequate social relations with other individuals and groups of individuals (states, corporations, etc.). It is, in general, an omission, a defect, or an exaggeration, connected with one or more of these great functions, that marks the passage from a normal to a deranged state of consciousness.

Among abnormal illusions are to be found some of the slightest and least serious delinquencies of mental function; delinquencies which are analogous to the lesser and more fleeting ills of the body. Instances are furnished by the mistaken perception of ghosts and goblins under stress of strong imagination or high emotional tension, and the seeing of fantastic forms in fire, rock, and cloud. Illusions of this type may, however, rest upon other conditions; upon a general temperamental bias, or upon prejudice, or superstition, or excessive fatigue, or hunger, or upon the use of drugs, or, finally, upon disease. Hallucinations are closely related to abnormal illusions. The traditional distinction between the two has been handed down from the time of the French alienist, E. Esquirol (1838), who defined illusion as "a false perception of an object," hallucination as "a perception without an object." This distinction, though it has little psychological significance, possesses a certain value in diagnosis; for hallucinations, as thus conceived, indicate a more serious psychological derangement than illusions. A relatively small number of hallucinations depend, as a matter of fact, upon the brain alone; in most cases, a peripheral disturbance, somewhere throughout the body, is their ultimate condition. Thus the hallucinatory belief that a part of the body is dead may come from a local paralysis or the conviction that the bones are tubes of glass from deranged organic sensations. Hallucinations are far less frequent in the sane and healthy than are the illusions described above. (See PSYCHICAL RESEARCH.) They are, however, frequent accompaniments of certain nervous disorders, for example, epilepsy and hysteria, and in ecstasy, in the dancing epidemics of the Middle Ages and in demoniacal possession, hallucinations have played a prominent part; while in those forms of insanity which are accompanied by cloudiness of perception and thought (delusional insanity, paranoia, and general paralysis) they are extremely frequent. *Dreams.* The dream consciousness is chiefly a perceiving consciousness; will, sentiment, memory, and reasoning are much less prominent than in waking life. But it is, nevertheless, a consciousness which does not fulfill the normal functions of perception. Dream perceptions are "unreal," and may, therefore, be considered as derangements; although they are no more pathological in their nature than the sleeping state in which they occur. The dream state is further characterized by diffuse unconcentrated attention and by loose and scattered associations. *Hypnosis.* One degree further removed from the normal mind than the dreaming state is the state of hypnosis. The two states possess, however, certain significant points of resemblance and of difference. (1) In both, consciousness is more or less cut off from the influence of the outside world. In sleep, the avenues of sense are closed. We seek darkness and quiet, avoiding, in general, conditions which would make demands upon the organs of sense and of movement. Furthermore, the sleeping state itself tends to protect the nervous system from intrusion; the sensory paths are blocked. In hypnosis, similar conditions obtain. There is a general insensitivity of the nervous system; so that appeals from the environment are, as a rule, unsuccessful. The subject is unaware of what is going on about him. (2) Again, both in dreams and in hypnosis, certain stimuli are effective. The course of dreams is partly determined by strong or persistent appeals from

without, for example, the chirp of insects, the rumble of traffic, the chill of the room, the cramp of an uncomfortable position. The course of the hypnotic consciousness is similarly determined by the words and gestures of the operator. (3) The dream and the hypnotic consciousness share a common attitude of belief in whatever situation is presented. Capacity for discriminating the world of sense from the world of memory and of imagination is lacking to both. The individual is completely credulous. The past and the future are, for the time being, annihilated. The person lives only in the present. (4) Along with these similarities there stands a striking and a fundamental difference between dreams and hypnosis. The dream consciousness is broad and shallow. Associations run riot. The selective function of the attention which, in the normal consciousness, rejects the trivial and the accidental and fixes upon the essential features of the perception or the idea, is lacking. One thing appears as important and as valuable as another. There is no subordination. Consciousness is scatter-brained. Consequently, the dream is (as one discovers upon waking) absurd and fantastic. In hypnosis, on the contrary, consciousness is deep and narrow. Along with the general insensitiveness just noted (anæsthesia) there goes a special high sensitiveness (hyperæsthesia). The slightest sound or gesture of the operator is caught up by the subject and acted upon. This special sensitiveness — not occult power in the operator — is the secret of *rapport*. The immediate and uncritical response of the hypnotized subject is due to his own abnormal psychophysical condition and not to any "force" exerted from without. Although certain of the physiological phenomena of hypnotism are to be found in some of the lower animals, in the state of catalepsy, human hypnosis is, on its conscious side, essentially a social phenomenon. It rests upon the general fact that all persons are, even in normal life, suggestible; that is, that their beliefs are largely determined by the personal or social influence which the individual exerts over his fellows. This influence shows itself normally in a mood or intellectual attitude of acquiescence. When the mood grows strong and overpowering — as in the presence of a captivating rhetorician — it becomes the attitude of obedience, of submission to authority. Now, in the abnormal state of hypnosis, the mood of submission is heightened, by the narrowing and deepening of consciousness, to the exclusion of all contrary and inhibitory associations. The result is that the beliefs and, consequently, the actions of the subject are entirely at the mercy of the meagre perceptual processes supplied, by way of "suggestion," from the operator. Hypnosis is, then, an abnormal psychophysical state which nevertheless closely resembles, in certain prominent features, both the dreaming and the waking states of everyday life.

2. *Permanent mental derangements.*— There is no general agreement among alienists regarding the precise limits of insanity. Some alienists regard practically all classes of mental disease as falling under insanity; others restrict the term to those derangements of mind which show a distinct loss of equilibrium among mental functions. The meaning of the term is, however, approximately fixed by practical and legal considerations; an individual is often pronounced insane when his mental condition so paralyses or perverts his personal and social relations that detention and treatment in a hospital for the care of the insane appears advisable.

On the border line of mental alienation stand such derangements as hysteria, neurasthenia, and hypochondria. It is clear that these affections stand on a different plane of abnormality from dreams and hypnosis, on the one hand, and from more serious forms of insanity, on the other. They are all of interest to the psychologist (but especially hysteria) because they present typical abnormalities of development, of the state of attention, and of the functions of memory, volition and emotion. Consider hysteria. The hysterical is abnormally absent-minded. The range of her attention is exceedingly narrow, so that she may, for example, in observing an object before her eyes, become quite blind to all other objects in the range of vision. Her capacity for learning is inhibited. She suffers a partial or total loss of memory (amnesia). The will power is impaired (abulia). The patient becomes a victim to habits of automatic action and to uncontrollable emotions and moods. Hysteria furnishes, moreover, a rare field for the study of suggestion and for the analysis of personality. French psychologists, who work by preference from the abnormal to the normal mind, have recently made important contributions to our knowledge of this form of mental disease.

When we come to insanities proper, we find a bewildering number of symptoms and of diseases. Out of these we can, however, extract a few general and typical forms. These include mania, melancholia, circular insanity (all distinguished by abnormal emotions and moods), delusional insanity (distinguished by fixed, irrational beliefs of grandeur, unseen agency, persecution, etc.), volitional derangements whose various forms (destructive, homocidal, dipsomaniac, kleptomaniac, etc.), are characterized by the lack of voluntary control, and, finally, a class of mental diseases which present the most complete and general loss of function — the highest degrees of mental abnormality. This class includes general paralysis, amentia, and dementia.

3. *Defective and exceptional minds.*— Our third class of abnormality covers (1) minds that are lacking in certain simple processes common to all normal individuals (the mind of the congenitally blind and congenitally deaf, the color-blind, and persons suffering from various impairments of the function of speech), (2) minds in which some set of processes or some function is abnormally developed (phenomenal chess-players, "lightning calculators," and trance "mediums"), (3) the genius, (4) the habitual criminal, the sexual pervert, and other "degenerates."

The deficient minds of (1) are of interest to the psychologist inasmuch as they show, by their very deficiency, the part played, in consciousness at large, by the lacking elements. The comparison, that is, of a normal mind with a mind wanting in visual or auditory sensation or verbal imagery is important for the psychology of vision or of audition or of language. The comparison is useful also in a study of mental substitution; for the functions of memory, imagination, and social communication

ordinarily borne by visual, auditory and motor imagery must, in the affections named, be borne by other mental processes. Finally, the mental aberrations to be found in the habitual criminal and the pervert bring the psychologist back to the domain of mental pathology and, at the same time, they offer material for investigating the influence upon mental constitution of hereditary tendency.

Asst. Prof. of Psychology, Cornell University.

Abolitionists, the extreme section of the anti-slavery party in the United States, who advocated immediate sweeping away by the national government of Southern slavery, without regard to constitutional guarantees, vested interests, or political facts; this section and its nickname date from about 1835. Gradual abolition had been the desire of many of the best men even of the South; and till after the War of 1812 there was no prejudice against the freest expression of opinion on the subject. But the effects of Whitney's cotton-gin were now beginning to be felt in making the slave system for the time enormously profitable; and the Missouri Compromise, with the insistence of the South thereafter that States should be admitted only in pairs, one slave and one free, showed that the time of apathy had gone by. The new zeal of the South in upholding, increasing, and justifying the system was met by a new intensity of the North in opposing it, though for a long time confined to a small band of agitators. In 1833 the National Anti-Slavery Society was formed in Philadelphia; in 1831 William Lloyd Garrison had founded the *Liberator*, a weekly continued till 1866, filled from the first with the fiercest denunciation not only of the system but of all connected with it; and a brilliant band of orators, philanthropists, and growing political forces,— Wendell Phillips, Charles Sumner, Gerrit Smith, and women like Lucretia Mott,— kept the public mind on the alert and furnished a monotonous moral to the course of political events which the people might not otherwise have drawn so readily. There were grades even among these; and the extremists denied the duty of obeying the United States Constitution, since it contained the clause warranting the fugitive slave law, which was denounced as "a covenant with death and an agreement with hell." In practice they violated it systematically by assisting in the escape of runaway slaves, through the machinery known as the "Underground Railroad," concealing them from pursuit and forwarding them from stage to stage till they reached Canada. But in 1840 the abolitionists divided on the question of the formation of a political anti-slavery party, and the two wings remained active on separate lines to the end. It was largely due to the abolitionists that the Civil War, when it came, was regarded by the North chiefly as an anti-slavery conflict, and they looked upon the Emancipation Proclamation as a vindication of this view. See Anti-Slavery Society; Liberty Party; Slavery; United States — Causes of the Civil War.

Aborigines (Lat. "from the origin"; the Greek name was *autochthonoi*), the earliest inhabitants of a country discoverable by civilized investigation. Their relation to the animal world as a whole comes under the head of Anthropology; to other races, under Ethnology; their culture and conditions, under Archæology; of special countries, under their names, or those of particular tribes. Specifically, in Roman writers, a race traditionally said to have been driven by the Sabines from their first homes in the mountains around Reate (Rieti), invaded Latium, subjugated the native Siculi and occupied the land, along with a tribe of Pelasgi, the two thenceforth taking the name of Latini. If true, these Aborigines would be of Oscan stock and form the non-Pelasgian element in the Romans.

Abortion, the expulsion of a fœtus from its natural resting-place before it is capable of carrying on its own life. A variety of different terms have been applied to indicate variations in the character of this process; thus: accidental, when brought about by purely accidental means; artificial or induced, when caused for medical therapeutic reasons; criminal, when induced for social rather than medical exigencies; tubal, when rupture of the Fallopian tube occurs, discharging the fœtus into the abdominal cavity, the pregnancy being extra-uterine.

The causes for this accident, apart from induced abortion, may be due to paternal, maternal, or fœtal defects. The proportion of abortions to full-time pregnancies is about 1 to 7 or 10. Of the paternal causes, alcoholism, syphilis, old age, or physical weakness may be cited. The most frequent causes, however, are of fœtal and maternal causes. Death of the fœtus is the most frequent fœtal cause. The maternal causes may be local or constitutional. Inflammation of the membranes of the uterus, tumors or new growths of the uterus, disease of the ovary, and inflammatory adhesions of the closely associated organs, act as local causes. Alcoholism, starvation, as in times of famine, syphilis, lead poisoning, coal-gas poisoning, acute diseases, as typhoid, pneumonia, and sudden severe shock, are the most common agents acting on the mother that bring about the death of the fœtus and its subsequent expulsion.

The symptoms are hemorrhage, discharge of the amniotic fluid, and pain. The treatment is always medical. The dangers are mostly those of hemorrhage and blood-poisoning.

In law, when abortion is produced with a malicious design, it becomes a misdemeanor, and the party causing it may be indicted and punished. When, in consequence of the means used to produce abortion, the death of the woman ensues, the crime is murder. In all cases of abortion the body of the offence must first be proven. The fact of the pregnancy, the use of the instruments, and the administering of the drugs must be established beyond a doubt. The evidence of the woman upon whom the abortion was committed is admissible but her dying declarations are not admissible unless homicide is charged. A person who sells a drug or instrument, knowing that it is to be used for the purpose of causing a miscarriage, is also guilty of a misdemeanor.

Abra, ā'-bra, a province and a river in the N. of Luzon, Philippine Islands. The province contains numerous deposits of placer gold, and the river gravel is auriferous. Other minerals, such as coal, copper, lead, iron, and sulphur, are believed to exist in paying quantities, as Luzon is known to be rich in these and other economic minerals. For its head-hunting tribes, see IGORROTE; PHILIPPINES.

Abraham or **Abram,** the progenitor of the Hebrews and the Arab Bedouin. After deriving his genealogy through Shem to his father Terah and his brothers Nahor and Haran, the narrative in Gen. xi.–xxv. proceeds as follows,— each step in the pilgrimage being by express direction of Yahwé, to his purpose of founding the Hebrew nation:—

After Haran's death Terah removes with his family from his native Ur of the Chaldees (? Mugheir in southern Babylonia), north to Haran, where he dies. Abram then (at 75) takes his wife Sarai and his nephew Lot, Haran's son, and makes his way north by way of Damascus (stopping to build altars to Yahwé at Shechem and Bethel) to Canaan, where he receives the promise that he shall become the founder of a great nation, and all the families of the earth shall be blessed in him. Being a pastoral nomad, a drouth in Canaan forces him to seek forage in fertile Egypt; where he passes off Sarai as his sister, in fear that her beauty will lead to his murder to possess her, and she is taken by Pharaoh, who, on discovering the deception, restores her, but orders Abram out of Egypt. Accompanied by Lot, he returns to a former encampment between Bethel and Ai. The clans of the two kinsmen quarrel over the limited pasturage, as usual with nomad tribes, and Abram proposes that each follow his own fortune. Lot, wishing to quit nomad life, chooses the fertile Jordan plain; Abram pitches his tent among the oak groves of Mamre, close to Hebron, and the previous promise of his posthumous glory is repeated and solemnly covenanted. Lot is captured in a raid of the Babylonian king, with his Syrian and other allies, against his revolted vassals of the Dead Sea and Jordan valleys, including the kings of Sodom and Gomorrah, who are overthrown; Abram sallies out to his rescue with a band of tribesmen, beats the confederacy and chases them near to Damascus, and not only recovers his nephew but restores the above kings to their thrones, refusing any reward. The property of the childless Abraham is to descend to his trusted servant Eliezer, and Sarai suggests that he avoid this by having a child from a concubine, a common enough arrangement; accordingly he has Ishmael by Sarai's maid Hagar, at 86. Four years later it is revealed by Yahwé in person to Abram that he shall have a legitimate son by Sarai, whose name is thenceforth to be Sarah (princess) and his own to be Abraham (father of peoples); the promise is afterward repeated by Yahwé and two angels, who visit Abram's tent in human form, the latter going on to destroy Sodom and Gomorrah for their wickedness, and the former staying behind to inform Abram of it. Abram's plea wins a promise of mercy contingent on ten righteous men being found there, but they are not forthcoming, and only Lot and his family escape. Abram goes to Gerar (Negeb) in southern Palestine, repeats precisely the same performance with the nonagenarian Sarai as before, and the king Abimelech repeats the part of Pharaoh, with the same apologies and reproaches. Isaac is born, Sarah being 90, and Hagar and her boy Ishmael are driven into the desert by Sarah's jealous fears, where Ishmael becomes ancestor of the Bedouin. Isaac is circumcised at eight days old, as a token of Yahwé's covenant with Abraham. Some time in Isaac's boyhood Abraham is commanded by Yahwé to make a burnt-offering of him, and proceeds to obey, but is spared the sacrifice by Yahwé, who accepts a stray ram instead and blesses him for his faith. Sarah dies in Hebron and is buried in the cave of Machpelah, which Abraham buys of Ephron the Hittite. He later marries Keturah, has six sons by her, dies at 175, and is buried beside Sarah. Isaac has previously married Rebekah, so that the succession is assured.

The Jewish stories of Abraham were by no means confined to this account in our canonical book; they had many others, associating him with Nimrod, etc., which are collected in the Talmud; and the Mohammedans invented or preserved many more. The critical view is that there was a real Abram or Abraham (the traditions existing in both forms), with his home at Hebron, probably a considerable man from the number and persistence of the legends about him; but that this is all we know. The names of his brothers and ancestry are not persons but Arab clans, and their relations and movements represent what was handed down or believed concerning the North-Arab league that grew into the Hebrew nation, or its original elements. The path of the "bne Terah" from the southern Euphrates valley into Palestine and elsewhere is certainly a correct type of the actual course, as revealed to us by archæology, of the Semitic tribes who century after century poured out of the Arabian deserts, into and up through western Mesopotamia, to plunder or share the rich Babylonian civilization and wealth, as the barbarians did that of the Roman empire; according to the resistance they found they stayed in the Moabite district, turned west to overrun the Jordan valley, or moved north into Syria. For the archæological results see the chapters on early times in various histories of the Hebrews, Kittel's, Stade's, Guthe's, etc.; Sayce's 'Patriarchal Palestine' and 'Early History of the Hebrews,' reverent in tone; Tompkin's 'Studies on the Times of Abraham.' Critical commentaries on Genesis are also serviceable. For the rabbinical legends, the sources — in German — are Beer on the life of Abraham, and Grünbaum on the 'Semitic Sagas,' which gives the Mohammedan legends likewise.

Abrahamites, (1) A 9th-century sect of Syrian deists, denying the divinity of Christ. (2) In modern use, the Bohemian deists of the later 18th century, who called themselves followers of Huss, but accepted no religious doctrine beyond the unity of God, and nothing of the Bible but the Lord's Prayer. They avowed this creed in 1782 on Joseph II.'s promise of toleration; but as they would join neither Jewish nor Christian folds, he expelled them from Bohemia the next year and scattered them through Hungary, Transylvania, and Slavonia. Many were martyred, others turned Catholic.

Abram. See ABRAHAM.

Abrasives, or those substances used in grinding or polishing, include (*a*) mineral substances, such as grindstones and whetstones, which are used by simply shaping up the material found in nature; (*b*) mineral substances which occur disseminated in the rocks or which must first be freed from impurities and are prepared for use by an initial pulverization; (*c*) artificial abradants. The history of abrasives shows that in ancient times the first class was most largely used, while the artificial abrasives now so extensively employed, were unknown until quite recently.

(*a*) *Oilstones and Whetstones* (q.v.) are largely American products. For nearly a century New Hampshire has been the headquarters of the whetstone industry. Whetstone rock is also found in Vermont, Massachusetts and Indiana. The best oilstones from New Hampshire are inferior to those of Garland County, Arkansas, in which region there are extensive beds of a remarkably compact, white, Paleozoic quartz rock, called Novaculite. Griswold in 1890 announced that this material is a sedimentary deposit of fine-grained quartz and not a chemically precipitated deposit as had been previously supposed. The quarries were largely worked for implements in prehistoric times and since 1840 they have yielded the finest oilstones known. These are sold under the names of «Washita» and «Arkansas» oilstones. The production of oilstones and whetstones in the United States during 1902 amounted to $221,762. The imports, chiefly of razor hones from Belgium and Germany, and of «Turkey» oilstones from Italy and France amounted to $56,456. Grindstones are manufactured from a tough, gritty sandstone, found chiefly in Ohio, though Michigan, Montana, Wyoming, and West Virginia add to the output, and England, Scotland, and Bavaria are also producers. The production of grindstones in the United States in 1902 amounted to $667,431. Millstones and buhrstones are far less used now than before the introduction of the roller process of making flour, for while the American production in 1880 amounted to $200,000, it fell in 1894 to $13,887. Since 1894 it has steadily increased till in 1902 it was $59,808. This is owing to the increased demand for buhrstones for grinding the coarser cereals, fertilizers, cement rock, and various minerals. Millstones are finer grained and more compact than grindstones. They are usually made from sandstone or a quartz conglomerate. The buhrstone (q.v.) from France is the best, but the stones from New York, Pennsylvania, and Virginia meet most of the requirements of the trade.

(*b*) *Pumice* (q.v.), a spongy lava, or a volcanic ash, is used in scouring powders and soaps. It comes chiefly from the Lipari Islands, but is also produced in Utah and Nebraska. Infusorial or diatomaceous earth occurs in beds often miles in extent. It is formed of the siliceous shells of infusoria and diatoms, and is used in scouring soaps and powders. The chief American localities are in Maryland, Virginia, New Hampshire and California. Tripoli is a similar variety of opal, but formed from a siliceous limestone by the leaching out of the calcium carbonate. Its use as an abrasive is as a polishing powder for metals, etc., but it is also extensively manufactured into filters, for which it is admirably adapted. Extensive deposits are worked at Seneca, Missouri, but the chief supply is imported from Tripoli. Crystalline quartz, of which over 15,000 tons were mined in Connecticut and Pennsylvania in 1902, is used as a wood finisher, in the manufacture of sandpaper, in the sawing of marble, for cleaning castings, etc. Garnet (q.v.) occurs in many of the crystalline rocks, especially in pegmatite and mica schist. Many varieties are recognized by the mineralogist; but the value of garnet as an abrasive, aside from its great hardness, is dependent not on its composition, but on its structure. If this is distinctly lamellar the material will continually present the sharp edges which are so essential to a good abrasive. Garnet which lacks this lamellar structure is of comparatively little efficiency for grinding and smoothing. Garnet-paper is much superior to sandpaper and is extensively used in woodworking and finishing the soles and heels of shoes. The most important localities are in New York, Connecticut, Pennsylvania, and North Carolina. Corundum (q.v.), being the hardest mineral known, except the diamond, ranks next to it among the natural abrasives. It occurs in enormous quantities in Ontario, which since 1901 has been the leading producer. It is also extensively mined in Montana, while North Carolina and Georgia have until very recently furnished nearly all of the domestic supply. Small quantities of corundum are produced in India which go chiefly to the English market. Emery (q.v.) is a natural mixture of corundum with magnetite or hematite. It has been largely mined at Chester, Mass., and Peekskill, New York. The chief supply, however, comes from the Island of Naxos, Greece, and from Asia Minor. The material is brought to this country as ballast and owing to the low prices at which it is marketed, the sale for the American mineral is much reduced. Diamond, owing to its far greater hardness, brings many times the price per carat which any other abrasive brings per pound. The black amorphous «carbonado» found in Brazil is much harder than the crystallized diamond, but it is almost exclusively used for diamond drills, while the dust of the South African «bort» is the material commonly employed as an abrasive in the cutting of diamonds and other precious stones.

(*c*) Among artificial abrasives, carborundum (q.v.) holds first rank. Discovered in 1890, its production has steadily increased from 1,000 pounds valued at $15 per pound in 1893, to 3,741,500 pounds valued at 8 to 10 cents per pound in 1902. It is generally acknowledged that it is exceeded in hardness only by the diamond, thus ranking above pure corundum. The chief objection to it is its brittleness. Carborundum wheels and stones, as well as carborundum cloth and paper, are now active competitors of the similar manufactures of emery and corundum. Crushed steel is extensively used in sawing, grinding, rubbing, and polishing marble, granite, and other stones, while the finer grades of crushed steel, known as «steel emery» and «rouge» are used in grinding glass. Artificial corundum is now being manufactured at Niagara Falls by heating the mineral bauxite in the electrical furnace.

For further particulars about abrasives see 'Mineral Resources of the United States,' published annually by the United States Geological Survey.

George Letchworth English,
Mineralogist, New York City.

Absalom, third son of King David (2 Sam. xiii.–xv., xviii.; 1 Chron. iii. 2). He revenged his brother Amnon's outrage of his sister Tamar by killing him, and was banished from his father's court for five years. The grudging re-admittance probably left him feeling insecure: he cleverly ingratiated himself with the people, and by aid of the shrewd Ahithophel organized a rebellion against his father, which took David unaware and forced him to fly east of the Jordan with a small following, while Absalom gained possession of Jerusalem and the court. With this enormous *de facto* advantage he might easily have maintained his seat; but according to the story, one Hushai, pretending to desert David, ingratiated himself with Absalom, and by cunning and flattery persuaded him to a policy of delay, while Ahithophel urged him to strike quick and hard, the obviously sensible course. David with this breathing-space collected an army; his veteran captain Joab, gray in victories and blood, routed Absalom's forces in «the wood of Ephraim»; and on report that Absalom had been caught by his long hair in the branches he was riding under, and refusal of the messenger to lay hands on the king's son, Joab himself dispatched him with his spear (about 980 B.C.). David could not have suffered the rebel to live; but the statement that he held a grudge against Joab for killing him, and ordered public mourning for his son, has nothing intrinsically improbable in it. Absalom is represented as a very handsome and charming prince, and the chronicler plainly has much sympathy with him.

Absalom and Achitophel, a satire of Dryden's, published 1681, with a second part next year mainly by Nahum Tate. It was aimed at the efforts of the Whig party to put forward the Duke of Monmouth, Charles II.'s illegitimate son, for the succession against the Duke of York, afterward James II. It is classic literature for the force and fire of its poetry, its intellectual keenness, and its brilliant characterizations of politicians of the «Popish Plot» time under the guise of Scriptural characters: the Earl of Shaftesbury as Achitophel (Ahithophel), Buckingham as Zimri, Slingsby Bethel as Shimei, Halifax as Jotham, etc.; also his poetical contemporaries Shadwell and Settle as Og and Doeg.

Abscess, a local collection of pus in a cavity formed by the breaking down of tissue. See SUPPURATION.

Abschatz, Hans Assmann, äp′-shats, FREIHERR VON, poet: b. Würbitz, 4 Feb. 1646; d. Liegnitz, 22 April 1699. A lyric poet of his day, whose poems were in great part called forth by his indignation at the predatory wars of the French. They are simple and without bombast, and show sincere feeling, pure sentiment, and a sturdy, patriotic mind entirely free from class prejudices. His ‹Poems and Translations› (1704) include a German translation of Guarini's ‹Pastor Fido.› Selections from them were edited by W. Müller in 1824.

Absecon, or **Absecum,** a bay and an inlet on the coast of New Jersey, northeast of Atlantic City.

Absconding, the going clandestinely or secretly out of the jurisdiction of the courts, or lying concealed, in order to avoid their process. A person who has been in a State only transiently or has come into it without any intention of settling therein cannot be treated as an absconding debtor (15 Johns. N. Y. 196), nor can one who openly changes his residence (3 Yerg. Tenn. 414). It is not necessary that the debtor should actually leave the State.

Absenteeism, a term applied to the owners of estates in a country who habitually absent themselves from that country and spend the income of their estates in it in another; in current use, referring almost wholly to the Irish nobility whose fixed residence is outside of Ireland. Much of the poverty and many of the disturbances in Ireland have been charged directly to it, and the Irish people have protested against it since 1380. While an Irish Parliament existed, there seemed hope for its gradual dwindling, careers being open for ambitious men in Ireland; but with its abolition the evil is almost incurable. Hungary suffered heavily from the same cause — its aristocracy looking on their native country's language and life as badges of barbarism, priding themselves on being Germans and living in Vienna — till the great national movement set going by Szechenyi and his companions early in the 19th century. Despite the defense of the system by some economists, and the good theoretical arguments that may be made for it, in practice its economic, social, personal, and political mischiefs are obvious. Not only is the absent landowner and property-owner, collecting his rents by agents, inaccessible to complaints, representations, appeals for help in upbuilding local institutions, etc., and unwilling to acknowledge rackrenting he does not personally see to be such (even a generous and kindly agent dares not be as lenient as he would, in fear of his master); but he should be the leader of his section, the fountain of careers, furnishing it employment, having his own success depend on its prosperity, and the active defender of its interests, and rights, and susceptibilities. The estate of an absentee owner, in fact, is essentially like a colony in the old conception,— a mine to exploit for outsiders who cared nothing for it; but the colonists of a distant province have a collective power much greater than that of the tenants of an absent landlord. Furthermore, it makes social co-operation for general needs almost impossible. The literature on this subject is nearly coincident with that of the Irish question as a whole; and the debates in Hansard's ‹Parliamentary Reports› abound in its discussion.

Ab′sima′rus, a soldier of fortune who raised, against the Byzantine emperor Leontius, an army which proclaimed him emperor, A.D. 698. He slit Leontius' ears and nose and threw him into a convent. He was taken in 705 by Justinian II., who, after having used him as a footstool at the hippodrome, ordered him to be beheaded.

Absinthe, a drink prepared from alcohol, the active principle of *Artemisia absinthium,* and other aromatics, notably the volatile oil of anise. Its frequent and prolonged use leads to a diseased condition known as absinthism that is a product of chronic alcoholism to which the

effects of the volatile oil of *Absinthium* are added. Other volatile oils probably contribute somewhat to the general result. Absinthism, in the main, is characterized by a greater amount of affection of the brain than is simple alcoholism. The action of the volatile oils is to heighten cerebral excitement, and absinthe-mania is a frequent result of this form of intoxication. See WORMWOOD.

Absolute, opposed to relative; means that the thing is considered in itself and without reference to other things.

In Logic.—(1) Absolute or non-connotative, according to Whately, is opposed to attributive or connotative. The former does not take note of an attribute connected with the object, which the latter does. Thus « Rome » and « sky » are absolute terms; but « Rome, the capital of Italy,» and « our sky » are attributive or connotative. (See Whately's ‹ Logic,› bk. ii., ch. v., §§ 1, 2–5.) (2) According to J. S. Mill, it is incorrect to regard non-connotative and absolute as synonymous terms. He considers absolute to mean non-relative, and to be opposed to relative. It implies that the object is to be considered as a whole, without reference to anything of which it is a part, or to any other object distinguished from it. Thus « man » is an absolute term, but « father » is not, for father implies the existence of sons and is therefore relative. (J. S. Mill's ‹ Logic,› bk. i., ch. ii.)

In Grammar, a case absolute is one consisting essentially of a substantive and a participle, which form a clause not agreeing with or governed by any word in the remainder of the sentence. In Greek, the absolute case is the genitive; in Latin, the ablative; in English, it is considered to be the nominative. In Latin, the words *sole stante* in the expression *sole stante terra vertitur* (the earth turns round, the sun standing still — that is, while the sun is standing still) are in the ablative absolute. In English, *thou leading,* in the following familiar quotation —

« I shall not lag behind, nor err
The way, thou leading —» (Milton)

is in the nominative absolute. So also is *I rapt* in the line —

« And, I all rapt in this, ‹Come out,› he said.»
— Tennyson's ‹ Princess,› Prol. 50.

In Law.—(1) Personal rights are divided into absolute and relative — absolute, which pertain to men as individuals; and relative, which are incident to them as members of society, standing in various relations to each other. The three chief rights of an absolute kind are the right of personal security, the right of personal liberty, and the right of private property. (Blackstone's ‹ Commentaries,› bk. i., ch. i.) Similarly there are absolute and relative duties. Public sobriety is a relative duty, while sobriety, even when no human eye is looking on, is an absolute duty. (Ibid.) Property in a man's possession is described under two categories, absolute and qualified property. His chairs, tables, spoons, horses, cows, etc., are his absolute property; while the term « qualified property » is applied to the wild animals on his estate. (2) An absolute decision is one which can at once be enforced. It is opposed to a rule *nisi,* which cannot be acted on until cause be shown, unless, indeed, the opposite party fail to appear. (3) Absolute law: The true and proper law of nature. (4) Absolute warrandice (Scotch conveyancing): A warranting or assuring against all mankind.

In Physics, absolute is opposed to relative. As this relativity may be of many kinds, various shades of meaning arise; thus: —

(1) Absolute or real expansion of a liquid, as opposed to its apparent expansion, the expansion which would arise when the liquid is heated if the vessel containing it did not itself expand.

(2) Absolute gravity is the gravity of a body viewed apart from all modifying influences, as, for instance, of the atmosphere. To ascertain its amount, therefore, the body must be weighed *in vacuo.*

(3) Absolute motion is the change of place on a body produced by the motion so designated, viewed apart from the modifying influence arising from disturbing elements of another kind.

(4) Absolute force of a centre: strength of a center.

In Astronomy, the absolute equation is the aggregate of the optic and eccentric equations.

In Algebra, absolute numbers are those which stand in an equation without having any letters combined with them. Thus, in the equation $2x + 9 = 17$, 9 and 17 are absolute numbers, but 2 is not so.

In Theology, God is often spoken of as absolute, because any relations he has to other beings are unessential to his nature.

In Morals, absolute ethics are those based on a fixed standard, independent of time or society.

In Metaphysics, the absolute is an existence apart from all attributes by which it is known as a phenomenon; but as it cannot be known except by the relation between such attributes and those already known to the mind, knowledge of the absolute, or of ultimate reality, is contradiction in essence, as the means of knowing it necessarily reduce it to a phenomenon. In other words, the absolute must exist apart from all relations, and knowledge itself is relation. It would be possible only to a being whose consciousness and the objects cognized were one and the same — that is, an existence which in itself is the universe both of objects and of mind at once, and those objects phases of its own mind — the Spinozan conception. Absolute space is considered apart from the material bodies in it. Absolute time is time viewed apart from events or any other subjects of mental conception with which it may be associated.

Absolute Zero.— The temperature at which bodies are entirely destitute of heat. For discussion of the principles upon which the determination of the absolute zero is based, see THERMODYNAMICS; ZERO.

Absolute, Sir Anthony, a character in ‹ The Rivals,› a comedy by R. B. Sheridan. He is a hot-headed, fiery-tempered, generous old man, always in a towering passion, even while he commends his own mildness of manner. His son, Captain Absolute, is the hero of the play.

Absolution, in ecclesiastical usage, the freeing from sin or its penalties. In the Catholic Church absolution has two important and distinctive bearings: (1) Absolution from sin; (2) Absolution from censures. The first is defined as the remission of sin, and can only be given

by a duly ordained priest in the Sacrament of Penance, which requires, on the part of the penitent, a sincere confession of all his sins, contrition and a firm purpose of amendment. The basis of the doctrine is the authority of the Church and the commission in John xx. 23. In circumstances, where the conditions of the Sacrament of Penance cannot be fulfilled, as in severe illness when the penitent is too weak to speak, or in instant danger of death, conditional absolution may be given on the ground of the moral conviction of the penitent's virtual desire to comply with all the necessary conditions. The Councils of Florence and of Trent defined the form of words to be used: "I absolve thee from thy sins, etc." In the Greek or Eastern Church the deprecatory form is used: "May Christ absolve thee, etc." Absolution from censures merely removes penalties imposed by the Church. It may be given either in the Sacrament of Penance, or in the external form, that is, in the courts of the Church. It is not necessary for the person to be absolved from censures, to be present or even living. Absolution for the dead is a short prayer imploring eternal rest and the remission of the temporal penalties of sin over a dead body. In the Protestant Churches in general absolution is simply a declarative power of the minister imploring the divine forgiveness. Consult: 'Decrees of Council of Trent'; Denys de St. Marthe, 'Traite de la Confession'; Morinus.

Absorption. In chemistry, absorption is the taking up of a gas by a liquid or by a porous solid; and in natural philosophy it is the taking up of rays of light and heat by certain bodies through which they are passing. Absorption of light is the retention of some rays and the reflection of others when they pass into an imperfectly transparent body. If all were absorbed, the body would be black; if none, it would be white; but when some rays are absorbed, and others reflected, the body is then of one of the bright and lively colors.

In chemistry the co-efficient of absorption of a gas is the volume of the gas reduced to 0° Cent. and 760 m. m. pressure, which is absorbed by the unit of volume of any liquid.

Absorption of heat is the retention and consequent disappearance of rays of heat in passing into or through a body colder than themselves.

Absorption of the earth is a term used by Kircher and others for the subsidence of tracts of land produced by earthquakes.

In physiology it is the taking in by the specialized cells of the products of digestion. See GASES, GENERAL PROPERTIES OF; LIGHT; OCCLUSION; SPECTRUM.

Abstract of Title, a synopsis, or brief statement, of the evidences of ownership of real estate. An abstract should set forth briefly but clearly every deed, will, or other instrument, together with every fact relating in any way to the title, in order to enable the party in interest to form an opinion as to the exact state of the title. The vendor of land, in England, usually furnishes the purchaser with an abstract of title. The vendor is not compelled to furnish an abstract of title in the United States. He usually undertakes to give only a marketable title. Plans and sketches of the premises are generally inserted in abstracts of title.

Abstraction. In psychology, that process of the mind by which the attention is concentrated upon one element of a complex idea to the exclusion of the other elements. In thought one object may be taken out — abstracted from — a group of objects, or one element separated from the group of elements that go to make up the object presented to our senses. Another form of abstraction is that process of the mind by which general notions or concepts are formed. The process of abstraction for the child begins in his noticing differences in familiar objects. Within certain groups some differences are found to be unimportant. These qualities which are found to be of less importance are then abstracted or removed from the complex idea for which the word denoting this group of objects stands. As this process develops it becomes deliberate, and the attention may be directed upon resemblances instead of differences. At this stage the grouping of objects according to likenesses results in classification. Consult: G. T. Ladd, 'Psychology, Descriptive and Explanatory,' New York, 1894; W. James, 'Principles of Psychology,' New York 1890; or any work on general psychology.

Absyrtus. See ARGONAUTS.

Abt, Franz, äpt, a German song-writer and conductor: b. Wiesbaden, 22 Dec. 1819; d. 31 March 1885. He studied theology at Leipsic, but abandoned it for music at Mendelssohn's instance. In 1841 he became kapellmeister at the court theatre at Bernburg; shortly afterward relinquishing the post for a similar one in Zürich, where he remained till 1852. He was then called to Brunswick as chief conductor of the orchestra in the royal theatre, and made court kapellmeister in 1855. In 1872 he came to the United States at the invitation of a number of choral societies, and was very favorably received; he conducted at the famous Peace Jubilee in Boston in that year. In 1881 he retired to Wiesbaden on a pension. Many of his songs (for example, 'When the Swallows Homeward Fly,' 'Good Night, Thou Child of My Heart,' 'O Ye Tears,' etc.), have endeared themselves to the heart of the people all over the world.

Abydos, Greece, town and castle of Asia Minor, on the Hellespont or Straits of Gallipoli, nearly opposite Sestus. It is famous as being the point from which Xerxes made his celebrated crossing of the Hellespont on the bridge of boats; and, also, as being the scene of the loves of Hero (q.v.) and Leander (see MUSÆUS). Byron adopts the name in his 'Bride of Abydos' (1813), characterizing it as a clime where "All, save the spirit of man is divine." It is thought originally to have been a Thracian town, but it subsequently became a Milesian colony. In 411 B.C. Abydos revolted from Athens and went over to Dercyllidas the Spartan. Subsequently the city was captured by Philip II. of Macedonia, but in 196 B.C. it was declared free by the Romans. Another Abydos was situated in Egypt on the upper Nile, and in the Thebaid was second in importance only to Thebes. It has become famous in modern times because of important ruins found there, the Palace of Memnon and the tomb of Osiris being among them. Here also was found the Tablet of Abydos.

Abyssinia, or **Habesh**, hä'-besh, an ancient kingdom of E. Africa, now under a monarch who claims the title of emperor. Pop. some 3,500,000. Abyssinia may be said to extend between lat. 8° and 16° N., and lon. 35° and 41° E., having Nubia N. and W., the Sudan W., the Red Sea littoral (Erythræa, Danakil country, etc.) E., and to the S. the Galla country. The area within these limits is about 160,000 square miles, but the present ruler claims a much more extensive territory; and latterly Abyssinia has come to be surrounded by regions belonging to or influenced more or less by Italy, France, and Great Britain. The principal divisions of Abyssinia are the provinces or kingdoms of Shoa in the south (including Efat), the strongest and best organized state in Abyssinia,— capital, Ankobar, of some 7,000 people, 8,000 feet above sea-level, with a salubrious climate; Amhara in the centre (including Gojam), capital, Gondar, situated on the Gondar plateau, 7,500 feet above the sea; and Tigré in the north, chief places, Antalo, and Adua or Adowa, with Axum near the latter, none of them much over 2,000 population. Adis Abeba in Shoa is the present residence of the ruler, transferred from Adowa after the Italian war, and has grown within two or three years from a small village to a city of some 80,000 inhabitants.

Topography.— The more marked physical features of the country may be described generally as consisting of a vast series of tablelands of various and often of great elevations, and of numerous ranges of high and rugged mountains, some of them of very singular forms, dispersed over the surface in apparently the wildest confusion. From these mountains flow inexhaustible supplies of water, which, pouring down by the deep and tremendous ravines that everywhere intersect them, impart an extraordinary fertility to the plains and valleys below.

The loftiest and most remarkable mountain summits occur in the centre of the northern part of the kingdom, immediately west of the Tacazzé River. Among the highest of these (so far as known) is Ras Dashan, calculated at 15,167 feet and capped with perpetual snow. Abba Yared and Buahit are estimated even higher. Along the eastern side of the country extends a mountain range or escarpment forming a natural rampart, with a mean elevation of 7,000 or 8,000 feet for some 600 miles. No volcanoes are known to exist at present, but almost everywhere are numerous evidences of past volcanic action. Perhaps the principal river of Abyssinia is the Tacazzé, rising in the mountains of Lasta, about lat. 12° N.; lon. 39° 20′ E. It runs north and then west, and after leaving the bounds of Abyssinia takes the name of Atbara, and finally joins the Nile. The chief of the other rivers — if not indeed the chief of all — is the Abay or Abai in the southwest, which after flowing through Lake Dembea, runs south and then northwest, and later becomes the Bahr-el-Azrek or Blue Nile, of which it is in fact the upper portion.

Fauna.— The domestic animals consist of horses, cattle, sheep, goats, camels, mules, and asses. Mules, camels, and asses are the usual beasts of burden, the horses being generally reserved for war and the chase. Vast herds of oxen are met with throughout the country. The wild animals are the lion (rare), elephant, hippopotamus, rhinoceros, crocodile, buffalo, hyena, leopard, boar, antelope, zebra, quagga, giraffe, gazelle, and civet. The hippopotamus abounds in Lake Tsana, and great numbers are killed annually for their flesh and hides. The rhinoceros, like the elephant, inhabits the low, moist grounds, and is numerous in certain districts. Crocodiles are found in various rivers, but the largest and most dreaded are those that inhabit the Tacazzé. The buffalo, a comparatively harmless animal in other countries, is here extremely ferocious. Serpents are numerous, among them being the boa, which often attains a length of 20 feet. Bees are numerous, honey being a general article of food; locusts often lay the land waste, and the tsetse fly is destructive to cattle during the rainy season.

Productions.— The chief mineral products of Abyssinia are iron, sulphur, coal, and salt. Coal-beds extend along the whole of the eastern frontier of Shoa, but as a combustible coal is scarcely known in the country. Salt is obtained in various places, especially from a plain on the southeastern border of Tigré. Gold is obtained from alluvial deposits, but not in great quantity. In some parts of the country iron is abundant and is manufactured into implements. A few hot mineral springs are known and used.

Climate.— The climate of Abyssinia is as various as its surface. In the valleys it is delightful, but on the mountains often cold. The rains begin in June and continue till September (over a considerable portion of the country at least), during which period they are often so violent as to put a stop to agricultural labor and all other outdoor operations. The finest months of the year are December and January.

Commerce.— The foreign trade is chiefly carried on through Massowa, Berbera, Zeila, Jibutil, Obok, and other non-Abyssinian ports on the Red Sea and Gulf of Aden; but the external traffic has never been of great importance, as the nature of the country is adverse to an extensive trade, and there are relatively few commodities suited for export; moreover, till recently the natives dared not trust their treasures out of their secret hoards, and the royal court was the chief buyer. Menelek's firm administration, however, with its better security for life and property, has recently been extending Abyssinian trade considerably, the United States and Great Britain being the chief beneficiaries, France and Germany ranking next. The imports of 1899–1900 into Adis Abeba, the capital, and Harrar, near British Somaliland, the chief trade centres, were about $3,500,000. The chief exports are coffee to Arabia, gold to India, wool, skins, ivory and rhinoceros horns, honey, wax, gums, civet, and ostrich feathers; the chief imports, cotton goods, in which American fabrics take the lead, silks, firearms and needles, bottles, tobacco, pepper, and antimony for cosmetics. Trade is greatly hampered by the primitive methods of communication, which is carried on by mules and pack-horses; the distance traversed being not above six to eight miles a day at best. Now, however, French capital is building — for politics, but none the less to the profit of trade — a railroad 184 m. long from Jibutil on the Gulf of Aden to Harrar, south-southwest, to be eventually extended to Adis Abeba; and the Italians are building one.

Arabs had invaded the country and obtained a footing in Adel, though they were unable to extend their conquests farther. For several centuries afterward the kingdom continued in a distracted state, now torn by internal commotions, and now invaded by external enemies (Mohammedans and Gallas). To protect himself from the last the emperor of Abyssinia, about the middle of the 16th century, applied for assistance to the king of Portugal, promising at the same time implicit submission to the Pope. The solicited aid was sent, and the empire saved. The Roman Catholic priests, having now ingratiated themselves with the emperor and his family, endeavored to induce them to renounce the tenets and rites of the Coptic Church and adopt those of Rome. This attempt, however, was resisted by the ecclesiastics and the people, and finally ended, after a long struggle, in the expulsion of the Roman Catholic priests about 1630. The kingdom gradually fell into a state of anarchy, which about the middle of the 18th century was complete. The Negus received no obedience from the provincial governors, who besides were at feud with one another and severally assumed the royal title.

Abyssinia thus became divided into a number of petty independent states. A remarkable, but, as it proved, quite futile attempt to resuscitate the unity and power of the ancient kingdom was begun about the middle of the 19th century by King Theodore, who aimed at the restoration of the ancient kingdom of Ethiopia, with himself for its sovereign. He introduced European artisans, and went to work wisely in many ways, but his cruelty and tyranny counteracted his politic measures. In consequence of a slight, real or fancied, which he had received at the hands of the British government, he threw Consul Cameron and a number of other British subjects into prison in 1863, and refused to give them up. To effect their release an army of nearly 12,000 men under Sir Robert Napier was dispatched from Bombay in 1867; it landed at Zulla on the Gulf of Aden in November, and marching up the country came within sight of Magdala, Theodore's capital, in the beginning of April 1868. Defeated in a battle, Theodore delivered up the captives and shut himself up in Magdala, which was taken by storm 13 April. Theodore was found among the slain, the general opinion being that he had fallen by his own hand.

After the withdrawal of the English, fighting immediately began among the chiefs of the different provinces; the three most powerful, Kasa, Gobasie, and Menelek, struggling for the supremacy. This state of matters continued for some time; but at last the country was divided between Kasa, who secured the northern and larger portion and assumed the name of Johannes, and Menelek, who gained possession of Shoa. Latterly Johannes made himself supreme ruler, with the title of emperor, or king of kings (Negus Negusti). Taking advantage of the troubles in Abyssinia the Egyptians annexed Massowa and adjoining territory on the Red Sea, and hostilities were repeatedly carried on between them and Johannes. In 1885 the Egyptian forces were withdrawn, and Italy, with the consent of Great Britain, declared a protectorate over Massowa and the strip of territory along the coast of the Red Sea. In the following year the Italians pushed inward to Saati, a few miles west of Massowa, an action which led to war with Johannes. An Abyssinian force was sent in 1887 to recover Saati; but though a small Italian force was cut to pieces at Dogali the Italians maintained their position.

On the death of Johannes in 1889, while fighting against the Mahdists, Menelek, who had concluded an alliance with Italy, raised himself to the imperial throne. The result of this was the strengthening of the Italian hold on the country. The Italians regarded their treaty with Menelek as giving them a protectorate over Abyssinia, and by 1892 the whole of Ethiopia was generally recognized as within the Italian sphere. Proceeding to extend and strengthen their position, the Italians in 1889 occupied Keren, capital of the Bogos country, situated 60 miles west of Massowa, and also fortified Asmara, southwest of Massowa. Adowa, the capital of Tigré, and the centre of opposition to Menelek, was occupied in the following year. The Mahdists were also defeated, and Kassala in the Sudan was occupied by the Italians. Menelek, however, later repudiated the Italian protectorate, broke with his former allies, and in 1896 his troops inflicted on them such a defeat as gave a death-blow to their claim of a protectorate over all Abyssinia. The treaty concluded in that year between Menelek and the Italians practically abrogated the treaty of seven years before, but left Italy in possession of a strip along the Red Sea coast from the French colony of Obok on the south to Ras Kasar on the north, known officially as Eritrea (Erythræa). A British mission in 1897 was favorably received by the emperor, and the boundaries between Abyssinia and the British Somali protectorate were arranged. In 1903, Robert P. Skinner of the United States Department of State negotiated a commercial treaty with Emperor Menelik. The American commissioner was impressed by the commercial possibilities of Abyssinia. He found the country admirably suited to cotton growing. Minerals are abundant, and the deposits are practically untouched.

Abyssinian Church, The. Founded by Frumentius, the first bishop of Ethiopia, about 330 A.D. About 470 a great company of monks established itself in the country, completely changing the doctrines and affairs of the Church, but was a few years later expelled. From 1528 to 1540, the country was overrun by Mohammedans, followed at the end of the 15th century by the Portuguese missions, which remained till 1633, when the Abyssinians resumed allegiance to the Church at Alexandria. The metropolitan or head of the Church is appointed by the patriarch of Alexandria, and is always a foreigner. The Abyssinians are monophysites, generally agreeing with the Copts in ritual and practice. The fasts are long and rigid; confession and absolution are strictly enforced and the Sabbath and the Levirate law are generally observed. Idolatry, purgatory, extreme unction, crucifixes, etc., are prohibited. The priests must marry, but only once. The liturgy is celebrated on the ark in the king's palace at Christmas, Epiphany, Easter, and the Feast of the Cross. The Scriptures are read in Geez, the literary language, which is used for all services.

Acacia (Gr. *akē*, spine, from their spiny stalks), a genus of plants, order *Leguminosæ*, sub-order *Mimoseæ*. They are trees or shrubs with compound pinnate leaves and small leaflets,— in some species wholly or partially undeveloped, when the petiole or leaf-stalk expands into a blade resembling a leaf, hence called phyllodium. It yields gum arabic, gum senegal, and other gums; some have astringent barks and pods, used in tanning. The Australian species contains considerable tannin, and hence is exported to a large extent. The Indian tree yields an astringent called catechu.

Acacius, a-kā'-shius, bishop of Cæsarea 340-365 A.D. He founded a curious Christian sect called Acacians, and that may be termed *homoiothelites*, as they held that the Son was like the Father in will, but not of the same or similar substance; thus differing from the Arians. He induced a synod at Constantinople in 359 to accept the doctrine, whereon St. Jerome said that «the world groaned and wondered to find itself Arian.» It was finally condemned, however, and he was banished.

Acacius, St., bishop of Amida in Mesopotamia, early in the 5th century. He sold the church plate to redeem 7,000 starving Persian slaves. Vararanes (Bahram), the king, is said to have been so affected by this noble action that he sought an interview with the bishop, which resulted in a peace between that prince and Theodosius II., A.D. 422, and a hundred years' peace was sworn between Rome and Persia.

Academics, a name given to a series of philosophers who taught in the Athenian Academy, the scene of Plato's discourses. They are commonly divided into three sects: (1) The Old Academy, of which Plato was the immediate founder, was represented successively by Speusippus, Xenocrates, and Polemon. (2) To them succeeded Arcesilaus, the founder of the Middle Academy. Under his hands the Platonic method assumed an almost exclusively polemical character. His main object was to refute the Stoics, who maintained a doctrine of perception identical with that promulgated by Dr. Reid in the 18th century. Socrates is said to have professed that all he knew was that he knew nothing. Arcesilaus denied that he knew even this. Wisdom he made to consist in absolute suspension of assent; virtue, in the probable estimate of consequences. He was succeeded by Lacydes, Telecles, Evander, and Hegesinus. (3) The New Academy claims Carneades as its founder. His system is a species of mitigated scepticism. He was succeeded by his disciple, Clitomachus. Charmides, the third and last of the new academicians, appears to have been little more than a teacher of rhetoric.

Académie des Beaux Arts, ak-ad-ā-mē dā bō zar. See ACADEMY OF FINE ARTS.

Academy, the gymnasium in the suburbs of Athens in which Plato taught, and so called after a mythical hero Academus, to whom it was said to have originally belonged. Anciently there were two public academies: one at Rome, founded by Adrian, in which all the sciences were taught, but especially jurisprudence; the other at Berytus, in Phœnicia, in which jurists were principally educated. Academy is the name also of a society or an association of artists, linked together for the promotion of art, or of scientific men similarly united for the advancement of science, or of persons united for any more or less analogous object. Thus the French possess the celebrated Academy or Institute. (See ACADEMY, FRENCH.) The use of the word "academy," different from the ancient one, is believed to have arisen first in Italy at the revival of letters in the 15th century. The nearest approach to these institutions in America is the Smithsonian Institution in Washington.

Academy, French, an institution founded in 1635 by Cardinal Richelieu for the purpose of refining the French language and style. It became in time the most influential of all literary societies in Europe. Together with the Academy of Inscriptions and Belles Lettres, the Academy of Moral and Political Sciences, and the Academy of Sciences, it composes the National Institute of France. It published in 1694 the first edition of a dictionary. It has exercised a conservative influence on French literature and favors taste rather than originality. It consists of 40 members, besides a director, a chancellor, and a secretary. In 1793 it was suppressed by the Convention, but was re-established in 1816. The French Academy originated in a simple meeting of friends who met at the house of Conrart, one of their number. These reunions were held informally for many years. At last they attracted the attention of Richelieu, who in 1634 proposed to form an Academy, and from the 13th of March in that year a record was kept of their transactions and a director or chancellor and a perpetual secretary were appointed. The Academy was definitely formed by letters patent of Louis XIII. in January 1635; they were registered by Parliament 10 July 1637. At first the number was 30. The perpetual secretaries since the foundation have numbered 19, and the incumbent receives a salary of 6,000 francs and lodgings at the Institute. Ordinary members receive 1,500 francs a year. In 1880 the discussion of the qualifications of candidates which had been in vogue for more than 10 years was abolished, but restored in 1896. In 1671 the sessions of the Academy became public. The library of the Institute was founded by Louis XIV., who presented to it 660 volumes. The members of the Academy, often spoken of as «the forty immortals,» were, in 1901, with the dates of their election: Ernest W. G. B. Legouvé, 1855; Duc de Broglie, 1862; Emile Ollivier, 1870; Alfred J. F. Mézières, 1874; Gaston Boissier, 1876; Victorien Sardou, 1877; Duc d' Audiffret-Pasquier, 1878; Aimé J. E. Rousse, 1880; René F. A. Sully-Prudhomme, 1881; Adolph L. A. Perraud, 1882; Édouard J. H. Pailleron, 1882; François E. J. Coppée, 1884; Joseph L. F. Bertrand, 1884; Ludovic Halévy, 1884; Vallery C. O. Gréard, 1886; Comte d' Haussonville, 1886; Jules A. A. Claretie, 1888; Vicomte de Vogüé, 1888; Charles L de Freycinet, 1890; Julien Viaud, 1891; Ernest Lavisse, 1892; Vicomte de Bornier, 1893; Paul L. Thureau-Dangin, 1893; Ferdinand Brunetière, 1893; Albert Sorel, 1894; José M. de Heredia, 1894; Paul Bourget, 1894; Henri Houssaye, 1894; Jules Lemaitre, 1895; Anatole France, 1896; Marquis de Beauregard, 1896;

Gaston Paris, 1896; André Theuriet, 1896; Comte Vandal, 1896; Comte de Mun, 1897; Gabriel Hanotaux, 1897; Claude J. B. Guillaume, 1898; Henri L. E. Lavedan, 1899; Paul Deschanel, 1899; Marquis de Vogue and Edmond Rostand, 1901.

Academy, The Royal Spanish, an institution established at Madrid in 1714 for the same purposes as the French Academy. The number of members is limited to 24.

Academy of Arts, The Royal, a British institution for the encouragement of painting, sculpture, and designing; founded in 1768 by George III., with Sir Joshua Reynolds as president. It is composed of a president (P.R.A.), 40 academicians (R.A.), and 20 associates (A.R.A.), which include professors of painting, architecture, anatomy, and perspective. It holds an annual exhibition, open to all artists, at Burlington House, London, of paintings, sculpture, and designs which reach a certain standard of merit.

Academy of Design, National, an American institution in New York city, founded in 1826, conducting schools in various branches of the fine arts, and holding semi-annual exhibitions at which prizes are awarded. The membership consists of academicians, who are the corporate body and use the title N.A. (National Academician), and the associates, who use the title A.N.A. (Associate of the National Academy), all, of necessity, artists. Laymen may become fellows of the academy on payment of graded fees.

Academy of Fine Arts, The, a French institution, originally founded in 1648 at Paris under the name of the Academy of Painting and Sculpture. In 1795 it was joined to the Academy of Architecture, and has borne its present name since 1819. It publishes memoirs, proceedings, and a dictionary of the fine arts. It has 41 members, besides corresponding members, etc.

Academy of France at Rome, an institution for the advanced study of the fine arts in Rome, Italy, founded by Colbert in 1666, during the reign of Louis XIV. It was at first established in the ruined villa Mancini on the Corso, and in 1803 at the villa Medicis. The young artists, painters, sculptors, architects, engravers, and musicians who secure the annual prizes of the Academy of Fine Arts in Paris spend four years there, with an annual pension of 3,500 francs and traveling expenses.

Academy of Inscriptions and Belles Lettres, an institution founded at Paris by Colbert in 1663, under the name of Petite Académie. It was composed originally of four members, chosen by the ministry to belong to the Académie Française. The first members, Chapelain, Charpentier, the Abbé de Bourzers, and the Abbé Cassagne, met in a salon of the Louvre or in Colbert's library, and devoted themselves to composing the inscriptions for the monuments erected by Louis XIV. and the medals struck in his honor; hence their popular name. They undertook a medallic history of the reign of the king. In 1701 the Academy assumed its definitive form; 40 academicians were named. In 1803 the Academy was reconstituted and became the third class of the Institute. Comparative philology, Oriental, Greek, and Roman antiquities and epigraphy, have received the attention of the Academy, which has published a series of invaluable records and works.

Academy of Medicine, a French institution, founded in Paris in 1820 for the purpose of keeping the government informed on all subjects appertaining to the public health. It has sections of medicine, surgery, and pharmacy, and its publications are highly prized by sanitarians.

Academy of Moral and Political Science, founded at Paris in 1795, became the second class of the Institute. It was suppressed by Napoleon in 1803, but was re-established by Louis Philippe in 1832, and forms the fifth class of the Institute. It is composed of 30 members, divided into 5 sections, with 5 free academicians, 5 foreign associates, and 30 corresponding members.

Academy of Natural Sciences of Philadelphia, an institution founded in 1812. It has one of the best natural-history collections in this country — especially rich in stuffed birds — and a valuable scientific library. It has published 'Journals' since 1817, and 'Proceedings' since 1841.

Academy of Political and Social Science, American, an institution organized at Philadelphia in 1889 and incorporated in 1891. It has a large number of members and publishes bi-monthly 'Annals.'

Academy of Sciences, an institution founded at Paris in 1666 by Colbert, and approved by Louis XIV. in 1699. It published about 130 volumes of memoirs from 1666 to 1793, when it was suppressed. It was re-established in 1816. It has now 66 members in 11 sections, with two perpetual secretaries and 100 corresponding members.

Academy of Sciences, The Imperial, a Russian institution, founded in St. Petersburg by Catherine I. in 1725, and largely endowed by Catherine II. It has 15 professors, a president and director, a fine library containing 300,000 volumes and many manuscripts, and a museum very rich in curiosities and objects of natural history. It has published 'Transactions' since 1728, and at present publishes two volumes annually, called 'Acta Academiæ,' including many memoirs on the higher mathematics and the astronomical observations at Pulkowa.

Academy of Sciences, The National, an American institution, founded in 1863, consisting of 100 members, elected from among the most distinguished scientific men of the United States; analogous to the Royal Society of London.

Academy of Sciences, The Royal, a Danish institution in Copenhagen, established by the king of Denmark in 1743. It has published transactions ('Skrifter') since its foundation, and memoirs ('Afhandlinger') since 1823.

Academy of Sciences, The Royal, a German institution in Berlin, founded by Frederick I. in 1700; had Leibnitz as its first director, and held its first meetings in 1711. It is divided into four sections, devoted to mathematics, physics, philosophy, and history. It publishes memoirs and monthly reports.

Academy of Sciences, The Royal, a Swedish institution, known also as the Royal Swedish Academy, founded in Stockholm as a private society in 1739; incorporated under its second name in 1741; issues annual volumes of 'Transactions,' which were at first published quarterly.

Academy of Sciences and Arts, American, an academy established in Boston in 1780 by the Council and House of Representatives of Massachusetts; the successor of an institution founded by Franklin. It has published monthly 'Proceedings' since 1846, and annual 'Memoirs' since 1785.

Acadia (Micmac, «plenty»). See NOVA SCOTIA.

Acadialite, a name given to chabazite (q.v.) from Nova Scotia (Acadia). Its color is usually salmon to flesh-red.

Acajutla, äk-a-hoot'la, Salvador, Central America: its second port in importance,— next to La Libertad, the port of San Salvador,— 10 m. south of Sonsonati, and the seat of a consular agent.

Acanthite, a mineral found chiefly in the silver mines of Bohemia and Saxony. It is a silver sulphide, Ag_2S, identical with argentite (q.v.) in composition, chemical and physical properties. but differs in form, its crystals being orthorhombic, their habit being prismatic and usually elongated. Krenner argues, however, and with considerable force, that acanthite is but a distorted form of argentite.

Acan'thus, the typical genus of the order *Acanthaceæ,* or acanthads, a natural order of monopetalous exogens, consisting of herbaceous plants or shrubs, found chiefly in the tropics, where they often form a large part of the weedy herbage. *Acanthus* is a native of many parts of southern Europe. The family is represented in America by a few wild-growing species; but they are best known as tender garden plants. The best-known species of the genuine acanths (or brancursines, as they were formerly called by a euphemism for the still older «bear's-breech»), are *A. mollis* and *A. spinosus.* The former has a stem about two feet high, surrounded in its lower half with large, soft, shining, hairy, and deeply indented leaves, and covered from the middle to the top with large white flowers tinged with yellow.

In Architecture.— The leaves of either *A. mollis* or *A. spinosus,* conventionalized and used for decoration. The latter only were used by the Greeks in the Corinthian capital, of which they were the characteristic, or in acroteria (see ACROTERION), and the leaves were three-lobed, straight, and pointed. The Etruscan and early Roman forms were of split curling leaves; the later Roman of the Greek trilobate form but using the *A. mollis* with its ampler foliage, and combining it with other leafage — olive, laurel, parsley, etc.— to make a luxuriant decoration of architectural features. The acanthus was also used in decorating furniture, table-ware, vases, embroideries, etc., and in frescoes. It was inherited by the Byzantine and Romanesque artists, and persisted till the Renaissance, when in some parts the Gothic displaced it.

Acaroid Resin, or **Gum,** a resin which exudes so abundantly from the grass-trees (*Xanthorrhœa*) of Australia as to cover the base of the leaves and the underground portions of the plants, and is also obtained by crushing and sifting or washing, as much as 50 or 60 pounds being obtained from one plant. Two kinds, red and yellow, are generally distinguished, and are used in varnishes as well as for several other purposes.

Acarus, a genus of insects of the tribe *Acaridæ,* order *Arachnida.* They are oviparous, have eight legs, two eyes, and two jointed tentacula, and are very prolific. All the species are extremely minute, or even microscopic, as the cheese-mite (*Acarus domesticus*), and many of them parasitic; of the latter, the itch-insect (*Sarcoptes scabici*) is a remarkable example. It is a microscopic animal found under the human skin in the pustules of a well-known cutaneous disease. Many others infect the skin of different animals, such as dogs, hogs, and cattle, and sometimes in considerable numbers. In some instances they damage cow-hides. (See MITES.) *Acarus folliculorum* is a microscopic parasite of the hair follicles of the skin. It is the lowest form of mite, and is known also as *Demodex folliculorum.* See BLACKHEAD.

Acceleration, the rate of change of the velocity of a body. If the velocity of the body is constant, its acceleration is said to be zero. If the velocity increases uniformly, so that at the end of every second it is greater than it was at the end of a preceding second by a constant amount, the acceleration is said to be uniform, and the motion is said to be uniformly accelerated. If the velocity is decreasing, the acceleration is said to be negative. A body falling freely under the influence of gravity affords the most familiar example of uniform (or constant) acceleration. When the body falls in air or any other medium, the phenomena are complicated by the resistance of the medium; but when it falls in a vacuum its velocity increases every second by the same constant amount. Thus if the body starts from rest, it will have a velocity of 32.2 feet per second at the end of the first second, 64.4 feet per second at the end of the second second, 96.6 feet per second at the end of the third second, and so on. The acceleration produced by gravity is therefore said to be 32.2 feet per second per second; but this varies somewhat with the latitude and the height above the sea. (See FORCE OF GRAVITY.) The acceleration experienced under given circumstances is proportional to the force acting upon the body in the direction in which its motion is accelerated. Thus if the foregoing experiment with a falling body were tried upon some other planet, and we found that the velocity of the falling body was increased by 322.0 feet per second every second (instead of 32.2 feet), we should know that the force of gravitation at the surface of that planet is precisely ten times as great as it is upon the surface of the earth. In physics and theoretical mechanics a force is always measured by the acceleration it produces when exerted upon a unit mass. For a further account of the relation between force, mass, and acceleration, also see FORCE.

Accent, the stress or emphasis given by the voice to a certain syllable or syllables of a word, or to certain notes in a bar of music; also, the peculiar intonation of one spoken language when compared with another; further, marks used in printing or writing to show the

position of the stress. In a dissyllable there is but one accent, as a-back', but in a polysyllable there may be more than one. One of these, however, is always greater than the rest and is called the primary accent; the others are called secondary.

Two wholly distinct classes of accent are found in Aryan languages, the musical and the expiratory; the former, which is that of some Semitic tongues also, being that of Greek and Sanskrit, the latter that of Latin and Teutonic. Some languages, as French, have no accent, the stress on all syllables being the same, but even here the stopping of the voice gives the final syllable a slight tilt upwards, with the effect of an accent on that syllable. Accent may be free, as in Greek or old Teutonic,— that is, its position in a word may shift in accordance with the nature of the syllables or of the words which follow,— or fixed, as in later Teutonic and English: perhaps the only remnant of the free accent in English is the word «cannot,» which, though often spelled as two words, is really a compound word with an accent shifting according to emotion. By a change of stress we often indicate the change of an adjective or a noun into a verb, as fre'quent (adj.), frequent' (verb); pro'ject (noun), project' (verb).

In compound words the accent is commonly on the first; but when the first element is a prefix, separable or inseparable, it is accented only when the root-word is noun or adjective, the root receiving the accent if it is a verb,— this of course not applying to words borrowed from other languages, for which there is no settled rule, the chance of first usage commonly determining it. The inflections have almost always been left unaccented, and this has aided greatly in the sloughing off of the whole inflectional system in modern languages: even where retained to the eye they are often not pronounced at all, as in French.

There is a certain analogy between accent and emphasis, emphasis doing for whole words or clauses of sentences what accent does for single syllables. One result of this has been to develop duplicate words with different meanings, as *of* and *off, to* and *too, through* and *thorough* (originally pronounced tho-roo'). All modern verse depends on stress-accent (see METRE); while that of classical Greek and Latin, as of some Semitic tongues still, rested on quantity or length of syllables,— a system not easy for those reared on stress to comprehend, much less imitate.

Marks of Accent.— In ancient Greek, accents marked the rise and fall in pitch of the voice, and were three in number, the acute (á), the grave (à), and the circumflex (ā or â). The same marks are now used in French, and the first two in Italian, though they are largely of historical or etymological interest only, and do not always indicate a difference in pronunciation. A mark similar to the acute accent is sometimes used to signify stress in English words, chiefly in poetry; and one like the grave is used to mark as a separate syllable letters otherwise not pronounced so, for example, learnèd, abhorrèd. Marks sometimes called accents are used in mathematics; for example, $a' + b'$ (read a prime plus b prime). In geometry and trigonometry, a circle at the right of a figure indicates degrees, one mark minutes, two marks seconds of a degree, as 13° 4′ 5″. In mensuration and engineering, the mark denotes feet, inches, and lines, as 4′ 6″ 10‴.

In Music.—The greater emphasis or intensity given to certain notes or passages, as distinguished from their length in time and their quality or *timbre*. It is divided into three classes,— grammatical, rhythmical, and rhetorical or æsthetic. The grammatical accent is almost always on the first part of a bar; long measures have usually secondary ones, as have polysyllables in words. Rhythmical accent is the more pronounced character given to certain parts of larger compositions,— phrases, themes, motifs,— to mark off entrances, finales, or climaxes. Rhetorical accent corresponds strictly to the same emphasis in oratory, in accordance with emotion or a desired effect, and is at the will of the performer.

Accentor («singer-together»), a literary name for the American water-thrushes (genus *Siurus*) and the European warblers, of which the British hedge-sparrow (incorrectly named) is best known.

Acceptance, a bill of exchange drawn on one who agrees absolutely or conditionally to pay it, according to the tenor of the document itself. To render it so valid that, if the drawee fails to liquidate it, the drawer may be charged with costs, the promise of the drawer should be in writing under or upon the back of the bill. An acceptance may be made before the bill is drawn, in which case it must be in writing (15 Johns. N. Y. 6). It may be made after it is drawn and before it becomes due, which is the usual course, or after it becomes due (1 H. Blackst. 313), or even after a previous refusal to accept. The proper form for the acceptance of a bill is to write the word «Accepted» across the bill and sign the acceptor's name, but the drawee's name alone is sufficient, or any words of equivalent force to «accepted.» Byles on Bills, 147; 21 Pick. Mass. 307. See BILL.

Access, Right of. The owner of land adjoining a road or public highway is entitled to access to such highway at any point where it comes up to his land. He may also have an action for the removal, by injunction, of any obstruction to such access, as well as an action for damages.

It has been expressly held also that an abutting owner has a property right in the use of the street in front of his land as a means of egress and ingress, and for light and air. 47 N. J. Eq. 421; 106 N. Y. 157.

If a man buys a lot of land from which there is no access to a public highway, upon application to the proper authorities he may obtain an order for the construction of a road or highway leading from his land to a public highway. See also RIGHT OF WAY.

Accession is the right to all which a man's own property produces, and the right to that which is united to it by accession either naturally or artificially (2 Kent, Comm. 360). If a man builds a house upon his own grounds with the materials of another, or, on the contrary, if a man shall have built a house with his own materials upon the ground of another, in either case the house becomes the property of him to whom the land belongs, for every build-

ing is an accession to the ground upon which it stands, and the owner of the land, if liable at all, is only liable to the owner of the materials for the value of them (2 Kent, Comm. 362). The same rule holds where vines, trees, fruits, and vegetables are planted or sown in the ground of another.

Accessory, in law, one who is not the chief actor in an offense or present at its commission, but still is connected with it in some other way. Accessories may become so before the fact or after the fact. Sir Matthew Hale defines an accessory before the fact as one who, being absent at the time of the crime committed, does yet procure, counsel, or command another to commit a crime. If the procurer be present when the evil deed is being done, he is not an accessory, but a principal. An accessory after the fact is one who, knowing a felony to have been committed, receives, relieves, comforts, and assists the felon. In high treason of a pronounced character there are no accessories — all are principals. In petit treason, murder, and felonies, there may be accessories; except only in those offenses which, by judgment of law, are sudden and unpremeditated, as manslaughter and the like, which, therefore, cannot have any accessories before the fact. So, too, in petit larceny and in all crimes under the degree of felony, there are no accessories either before or after the fact; but all persons concerned therein, if guilty at all, are principals. (Blackst. Comm., bk. iv., ch. iii.) Presence and actual participation are necessary to constitute a person an accessory. The mere fact of presence or failure to interfere to prevent the commission of a crime is not, alone, an indictable offense. The person must act in concert with the active party. He must by word or act contribute to the felonious purpose. Presence need not be actual, it may be constructive. A man may commit a crime through the agency of an innocent person, but the agent cannot be convicted. Where an offense is committed within a State by means of an innocent agent, the employer is guilty as a principal, although he did no act in the State where the crime was committed, and at the time of the commission of the offense was in another State. 1 N. Y. 173 (s. c. 45 Am. Dec. 468); 123 Mass. 430.

Accho. See ACRE.

Acciaioli, Renatus, ätch-yī-ō'lē, a Florentine who conquered Athens, Corinth, and part of Bœotia: lived in the beginning of the 15th century. He bequeathed Athens to the Venetians; Corinth to Theodosius Palæologus, who married his eldest daughter; and Bœotia with Thebes to his natural son Anthony, who also got Athens, but this was retaken in 1455 by Mohammed II.

Accident, an unforeseen occurrence, particularly if it be of a calamitous character. This is the most common use of the word.

In logic: (*a*) Whatever does not really constitute an essential part of a person or thing; as the clothes one wears, the saddle on a horse, etc. (*b*) The qualities or attributes of a person or thing, as opposed to the substance. Thus bitterness, hardness, etc., are attributes, and not part of the substance in which they inhere. (*c*) That which may be absent from anything, leaving its essence still unimpaired. Thus a rose might be white without its ceasing to be a rose, because color in the flowers of that genus is not essential to their character.

Accidents, in logic, are of two kinds, separable and inseparable. If walking be the accident of a particular man, it is a separable one, for he would not cease to be that man though he stood still; while, on the contrary, if Spaniard is the accident connected with him, it is an inseparable one, since he never can cease to be, ethnologically considered, what he was born. (Whately's ‹Logic,› bk. ii., ch. v., sec. 4.)

In grammar, a property attached to a word which nevertheless does not enter into its essential definition. Each species of word has its accidents: thus those of the noun substantive are gender, declension, and number. Comparison in an adjective is also an accident.

In law, an event which under the circumstances is unusual and unexpected by the person to whom it happens. It is the happening of an event without the concurrence of the will of the person by whose agency it was caused, or the happening of an event without any human agency. If a house should be burned in consequence of a fire made for the purpose of cooking, or warming the house, this would be an accident of the first kind. If the house should be set on fire by lightning, this would be an accident of the second kind. 1 Fonblanque, Eq. 374, 375 n. The best test of liability for the consequence of an accident turns upon the fact whether the person causing the accident was guilty of negligence or not. If he was guilty of negligence he would be liable unless the person injured was guilty of contributory negligence.

In heraldry, an additional note or mark on a coat of armor, which may be omitted or retained without altering its essential character.

Accident Insurance, a system which indemnifies the insured person for loss of business time resulting from disabling bodily injuries inflicted by external and accidental violence, or in case of death therefrom within a certain time pays the legal heirs a sum stated in the contract. The former is done by a weekly indemnity (graduated according to premium and hazard of occupation) paid in a lump sum on recovery or at the end of a fixed expiration term; or by a stated sum at once in case of irremediable mutilations. It is a system of *limited* health and life insurance, paying the benefits only in case of death or disablement from a specified class of contingencies instead of from any contingency; therefore bounded on the one hand by life insurance and on the other by the benefit societies, but less costly than the one and to larger amounts than the other. These boundaries of limitation are stated in the contracts: varying in detail, they are and must be in essence the same in all, as they reduce to the two classes which accident insurance exists by excluding, those which are not accidental and those which are not violent. These, however, form five individual groups: (1) Disease or bodily infirmity, direct or as indirect cause; (2) effects of one's own will, vice, or recklessness, as suicide, drunkenness, fighting or breaking the law, voluntary exposure to unnecessary danger, etc.; (3) legal sentences; (4) poison; (5) weather, except violent manifestations like stroke of lightning. These, however, are much

less simple in practical application than in theory and in some cases are virtually dead letters by popular prejudice or even legal enactment. The suicide clause has been scarcely enforceable for many years through the refusal of juries to find it as a question of fact; and of late years several States have passed laws invalidating it in any insurance contract. Drunkenness, though not barred by law, is so nearly impossible to make a jury accept that it is practically never entered in plea. The others are of course contestable and perpetually contested. Furthermore, different companies and forms of policy vary in the extent or severity of their exclusions, some waiving important factors in this list; and all of them now, under stress of competition, have added some portions of health and life insurance to the accident contract proper,— giving indemnities and payment of principal sum for loss of time or for death through certain contagious diseases.

The modern system of accident insurance dates only from 1848; but its purposes were fragmentarily embodied in earlier arrangements. The Hanseatic League, the originator of so many good business ideas, seems to have devised this; at least the Sea Laws of Wisby in 1541 mention the insurance of shipmasters by owners against the perils of the sea,— the insurance of their families of course. A mercantile treatise probably of the same century, compiled for the traders of Rouen, in France, states that « other nations » insure men's lives on voyage, « paying certain sums to their heirs or creditors »; possibly it refers to the same Hanse practice. In 1665 England applied a rough form of it to the casualties of warfare: a regular schedule of indemnities to be paid to soldiers in the Netherlands war was compiled, ranging from £62 10*s.* for both eyes or both arms, £50 for both hands, £29 4*s.* for both legs, and £18 15*s.* for both feet, down to £8 7*s.* for one foot, and with graduated amounts between. Later, a year's pay (not much then) for the loss of a limb was the customary gauge. But this was a mere pension system; and none of these had the essential feature of modern insurance, a business contract as matter of bargain and sale, with the insurance proportioned to the payment.

Modern accident insurance originated in England. Its germ, oddly enough, was primarily not personal but property insurance; not against bodily injury so much as loss of goods in railway accidents. The first charter applied for was for the British and Foreign Life and Property Insurance Co., which never organized; and the insurance of human beings was added apparently rather to make up a « blanket charter » than with much idea of profiting by it. But the swift clarification of business ideas on this point, due to the public horror of great railway accidents, — the concentrated volume of destruction in which makes them much more impressive to the imagination than the really far more formidable mass of scattered daily accidents,— is shown by the fact that of ten other similar charters granted in the next three years none of them mention goods in their titles, and most of them show that their business was personal insurance alone. All, however, had « Railway » in their names, and the « ticket » business was long supposed to be the only one feasible. Only 2 of these 11 ever organized, and the pioneer company, the Railway Passengers' Assurance Co.,— opened business 22 March 1849,— for a long time insured only passengers actually in the coaches, and by the terms of the policy (though not enforced) only covered them while moving, excluding even collisions at stations. Its first rival to be chartered (though not to begin business) covered also accidents on platforms, etc. But the real birthday of the modern general accident business is 3 June 1850, when another company adopted the plan of its actuary, Edward Riley, and extended its insurance to cover all violent bodily injuries.

The next field to be opened was among workmen in the manufacturing districts, their great hazards and consequent need of it making it seem that they would welcome it; but their poverty and ignorance overbalanced their requirements, and the experiment was a failure In 1852 Cornelius Walford suggested that the true field lay among the business and professional classes; and although this at first was scouted as fantastic, their individual hazards appearing too slight to found a great business on, it was followed by a brilliant success and the creation of the modern system substantially as it stands. Attempts were occasionally made to frame narrower schemes, as for carriage accidents alone, etc.; but no success has attended these experiments. A basis as broad as consistent with the essential nature of the business has been found the only one practicable.

The business in the United States was founded in 1863 by James G. Batterson, a Hartford builder, on a suggestion afforded by the Railway Passengers' Assurance Co.'s tickets, and after consultation with the officers of that company, who generously put all their experience at his disposal; it proved, however, to be very misleading for American conditions. On his return to Hartford he associated several other Hartford gentlemen with him, and a charter was procured for the Travelers Insurance Co.; but owing to entire popular disbelief in the system no business was done till April 1864, its first premium being one of two cents, paid in jest by a business man to insure himself in going from his house to his office. A storm of railway accidents about that time, however, shocked the public so that the enterprise soon became a brilliant success, though it was nearly ruined by the new companies which swarmed into the field. Five western States in the winter of 1864 chartered nearly 100 insurance companies of all kinds, over a dozen of them accident companies; and in April 1865, 25 of the latter were organizing in the United States. To save multiplication of ticket equipments at railway stations, where several companies sometimes had them on sale at once, the Railway Passengers' Assurance Co. was organized in May 1865, to consolidate all the ticket business under one head, with office in Hartford. In 1878 all the companies but the Travelers having been long dead, that company reunited the business to its own. There are now several strong companies in the United States, which heads the world in the volume of its accident business. None of them transact this branch of business alone: all combine it with employers' liability (q.v.) (indirect accident insurance, by a subrogated blanket liability to an employer instead of to his employees individually), and most of

them variously either with life, steam-boiler, elevator, plate-glass, surety, or other forms of personal guaranty. Owing to certain peculiarities of the business, its statistics are not easy to give; but it certainly protects a million of men and their families, and pays $20,000,000 a year for death and indemnity claims. About one-tenth of the insured are paid claims of some sort. The most hazardous of the large general occupations — excluding special hazards like the manufacture of gunpowder and dynamite — is that of freight brakemen; due not entirely to the inevitable perils of the employment, though they are large, but partly to the reckless bravado bred of familiarity. Next to these in hazard are the employees of rolling-mills. Among the business and professional classes, much the greatest volume of loss is from horse and carriage accidents, which are many times more destructive than railway accidents.

The development of the accident-insurance field should be noted. It may be compared with the origin of banking from note circulation, which afterward became a feature so insignificant as to be neglectible. Similarly, accident insurance arose from a desire to give protection against the results of railway accidents: but the losses from these do not constitute more than five or six per cent of the total losses among recent companies. Another significant fact is the change in the class mainly covered by it. Theoretically, it should find its chief patronage and profit among those hazardously employed: in fact, the larger companies found long ago that a great business can only be done among these under conditions that render it unprofitable, and after carrying it on for many years on the installment plan, have mostly been obliged to abandon it altogether and confine their efforts to the business and professional classes, or to such of the working class as have means to pay yearly premiums in advance. See INSURANCE.

Accipitres (Lat. plural of *Accipiter*, the common hawk), or *Raptores*. An order of birds, comprising the birds of prey,— eagles, hawks, owls, and vultures. See BIRDS OF PREY.

Acclamation («calling to»): properly, expressing any judgment of an assembly or a large part of it by shouting: but in usage restricted entirely to a favorable one. The choice of rulers among most early Aryan tribes or nations was by acclamation: the candidate was presented by a previous understanding — among the Vikings raised on a shield in the presence of the chiefs — and acclaimed by the voices of the assembled multitude. In some cases, as with the Poles even quite late in their history, the agreement was only made when the throng had gathered and there were more than one set of acclaimers, often ending in a pitched battle to decide which party preponderated. In the minor divisions of modern political life, voting by acclamation is usual; a ballot being called for only when the parties are so evenly balanced that the preponderance is dubious, or a small majority has great strength of lungs, or the minority wish to make the majority put their position on record, or simply to have the satisfaction of a proved vote. In ecclesiastical councils the vote by acclamation comes first also, the question being put as «*placet*» or «*non placet*.» In private matters, acclamation has been used from early times as an expression of good feeling or enthusiasm, as in the customary «hurrahs,» «huzzas,» and «tigers,» and the «hear, hear» of political assemblies, and the responsive shouts and groans of religious revivals or prayer-meetings. The applause in theatres, etc., being non-vocal does not etymologically belong to the group, but is usually included as having the same intent. It began with genuine applause, an actor closing the play by some word asking for approval of the company — in the Roman theatre, «*Plaudite*» («applaud ye»), or a poet or orator who recited in public expecting and receiving applause; but the *claque,* in modern French phrase, was very early organized by rich amateurs, who kept bands of paid applauders not only for their own use but to lend to friends. Nero had 5,000 of these, many of them *equites* or knights, to chant his praises at the direction of a professional music-master; they were called Augustiniani. In the modern French theatre the *claque* is on a more modest footing and is paid by the management; the understood reason being (curiously) that it keeps up the spirits of the actors when the audience's coldness might depress them beyond the power to play well, and more rationally that it guides and stimulates the audience itself to genuine applause when it might be simply sluggish and indifferent. In old times applause was shouted at marriages, as «Io Hymen,» «Hymenæe,» «Talassio»; in festal or religious processions; to victorious commanders in triumphs or ovations, as «Io triumphe»: and even, contrary to modern feelings of decorum, in churches, the pulpit orator being cheered at good passages.

Acclimatization, the gradual alteration which fits a plant or animal to a climate differing from that in which the habits of its species or race have been formed. Acclimatization and naturalization are often mistakenly used as synonymous, but naturalization properly means establishment in a new country, and, if the climates of the two countries chance to be the same, acclimatization is not implied. In the consideration of marine animals and plants acclimatization takes on a slightly different meaning, since aquatic life is more affected by the various conditions of the surrounding water than by climate.

In Plants.— Many examples of acclimatization are furnished by cultivated plants, among which the most noteworthy are perhaps the cereals. The original species of most of these has not been discovered, but in most cases it is supposed to have lived in sub-tropical or warm temperate regions. Some of these cereals now thrive far better or are more productive in cold, northern climates than in warm regions. But in such cases an important influence may to a greater or less extent obliterate or emphasize the apparent period of growth, the productiveness, etc. This is the daily duration of sunlight. During the growing period the sunlight lasts longer as the pole is approached, so that the shorter season is more than compensated for by the increased hours of sunlight. It has been found by experiment that certain varieties of corn brought from the southern States to the northern attained their customary height, but generally failed to ripen seed. The progeny of

such plants as did mature seed gradually assumed the characteristics of northern varieties; they reduced their height and shortened the time necessary to attain maturity. In a few years they resembled other northern varieties in these two respects. The reverse of this case has also been proved; northern varieties taken to the South at first reached the height and attained maturity in the time natural to them in the North, but gradually assumed the characteristics of southern varieties — increased height and greater number of days to reach maturity. But even considering the frequent preponderance of this influence and remembering that the production of seed is usually in opposition to marked development of vegetative parts, there is no doubt that plants, in becoming acclimatized, are compelled to adjust themselves to many other less prominent influences, such as humidity, temperature, light, and wind. The peach is supposed to have come from China by way of Persia, and since early historical times has gradually been fitting itself to more and more northern conditions. It is now found to be a profitable crop in Michigan and New York, which are several degrees farther north than its supposed place of origin. The influence of climate upon cultivated plants is recognized by progressive agriculturists and horticulturists, and each prefers seed grown in a more northerly locality than his own. The effects of the new environment, however, soon become evident, and new importations must be made. Seeds grown at high altitudes exhibit the same characteristics as those produced in high latitudes; that is, they are hardier and require a shorter period to reach maturity than those grown in low altitudes or low latitudes.

Among naturally acclimatized plants are many remarkable phenomena. Deciduous plants taken from cool climates to tropical conditions hold their leaves for a much longer period than where they are indigenous, or may even become evergreen like their new associates. Plants imported from warm regions to cooler may lose the power to ripen seeds, but this defect may be compensated by the development of vegetative reproductive powers. The reverse case is also true. Southern plants may fail to ripen wood completely, and winter killing may result. In cultivated plants, however, this phenomenon, which is often observed in the peach, may be due to improper methods of cultivation resulting in abnormal wood-development.

In Animals.—The capacity for acclimatization is possessed in very different degrees by different animals, even by different individuals of the same species, and depends much upon general hardihood. Exactly what changes take place during acclimatization is not known; sometimes the very specific gravity of the animal is altered, as when fresh-water fishes become adapted to the denser water of the ocean; similarly, the normal temperature of the individual may gradually become altered, as in the case of fishes native to cool water, which chance to work up-stream into hot springs and live there at a temperature which would kill normal individuals of the same species. The animals which are most wide-spread over the earth are those which have the greatest adaptability to new climates and new conditions of environment, and the best examples of this adaptability are found among domestic animals (q.v.). About the middle of the 19th century there was much enthusiasm for transplanting animals from one country to another; but the results have so often been harmful rather than beneficial to the recipients of the new forms that the effort to improve on nature in this way has been abandoned. Conspicuous examples are afforded by the sending of the European rabbit to Australia and New Zealand, where it multiplied so excessively in a favorable climate, with abundant food, and through the almost complete lack of enemies, as to become a nuisance and a menace to the pastoral industry. (See RABBIT.) The introduction of the agua toads, and afterward of the mungoos (qq.v.) into Jamaica, to subdue the rats that were devouring the sugar-cane, had evil results. The spread of the European house-sparrow (q.v.) in the United States is another pertinent example. Many highly injurious insects have been accidentally introduced and acclimatized in America from abroad; and the same is true of other countries. On the other hand a few instances like the acclimatization of the silkworm in Europe, of bumblebees in New Zealand, or of ladybirds in California, have been highly beneficial; while much good has come from stocking new streams with desirable fishes. Of the several societies founded to promote such transferences, that of Paris (Société d'Acclimatation) is most important, but latterly has been inactive.

In Human Beings. See HYGIENE.

Bibliography.— ‹Variations of Animals and Plants Under Domestication.› Darwin; ‹Island Life,› Wallace; ‹Tropical Colonization.›

Acco, ak'ō. See ACRE.

Accolade, äk-ō-låd' (Fr. «embrace,» literally, «on the neck»), in heraldry, the ceremony by which in mediæval times one was dubbed a knight. On the question what this was, antiquaries are not agreed. It has been made an embrace round the neck, a kiss, or a slight blow upon the cheek or shoulder. In some cases it was a literal box on the ear, for which later was substituted a gentle tap on the shoulder with the flat of a sword. In conferring knighthood Queen Victoria struck the kneeling subject lightly on the shoulder with a sword and used the words «I bid thee rise, Sir Knight.»

Accolti, Benedetto, äk-ol'tē, ben-a-det'ō, the Elder, distinguished Italian jurist: b. Arezzo, 1415; d. Florence, 1466. Several other members of his family were noted for legal attainments. He became professor of jurisprudence in the University of Florence, and on the death of the famous Poggio was made chancellor of that republic. With his brother Leonardo he wrote in Latin a three-volume history of the first crusade, not of great value, but interesting as having furnished Tasso the material for ‹Jerusalem Delivered›: pub. Venice 1452, Italian tr. 1543, French tr. 1620. He also wrote a volume of biographies of his distinguished contemporaries, pub. Parma 1689.

Accolti, Bernardo, äk-ol-tē, bĕr-nar'dō, Italian poet: b. Florence, before 1466; d. after 1534. He was greatly admired, especially as an improvisatore. Whenever he announced his intention of reciting his verses the shops were

closed and the people flocked in crowds to hear him. He was surrounded by prelates of the first eminence; a body of Swiss troops accompanied him; and the court was lighted by torches. Leo X. esteemed him highly and made him apostolic secretary, cardinal, and papal legate at Ancona. He it was who drew up the papal bull against Luther (1520). Though styled in his own day «The Only (one) of Arezzo» (L' Unico Aretino), the fame of his works perished with him. Their style is hard, his images forced, and his taste marred by affectation. The best known is a comedy, ‹La Virginia.› His other productions include some lyric poetry, epigrams, octaves, and verses in *terza rima*.

Accommodation, the process by which the mind is brought into adjustment with its surroundings; adaptation.

In physiology, the accommodation of the eye is the function by which objects, near or distant, may be seen distinctly. It is accomplished by the relaxing or contracting of the ciliary muscle. See Eye.

In biology, the process by which an organism becomes adapted to its environment.

In theology, properly, the presentation of a truth not absolutely, but with some modification to suit it either to some other truth or to the person addressed. It is distinguished as *formal* and *material,* the former relating to the method of teaching, and the latter to what is taught. The former includes teaching by parables or symbols, by progressive stages graduated to the capacity of the learner, etc.; more usually, now, the forcing of texts from their obvious meaning to conform them to theories derived from other sources. The latter, as now commonly used, means the theory that Christ and the writers of Scripture modified or perverted the truth to accommodate it to the limited intelligence or the prejudices of their times.— the cosmogonies of Genesis, or Jesus' acceptance of demoniac possession as a truth, etc.

In commerce it usually denotes temporary financial assistance rendered by one merchant or bank to another. Accommodation paper includes notes or bills of exchange made, accepted, or indorsed, without any consideration. While in the hands of the party to whom it is made, or for whose benefit the accommodation is given, such paper is open to the defense of want of consideration, but when received by third parties in the usual course of business it is governed by the same rules as other paper. (2 Duer, N. Y. 33; 2 Kent, Comm. 86.)

Accompaniment, in music, is that part which serves for the support of the principal melody (solo or obbligato part). This can be executed either by many instruments, by a few, or even by a single one; we have therefore pieces with an accompaniment for several, or only for a single instrument. The principles on which the effect of accompaniment rests are so little settled that its composition is perhaps more difficult than even that of the melody. Frequently the same musical thought produces a good or bad effect, according to the character of the accompaniment, without our being able to give a satisfactory reason for the difference. The accompaniment requires of the performer the most scrupulous study, and of the composer the greatest skill and delicacy. As the object of every musical accompaniment is to give effect to the principal part, the accompanist should always aim really to support and by no means to overpower it.

Accomplice is the term applied to one who is in some way connected with the commission of a crime, though not as a principal.

In the absence of a statute it is not a rule of law, but a rule of practice only, that a jury should not convict on the uncorroborated testimony of an accomplice. Ordinarily the judge will advise the jury to acquit unless the testimony of the accomplice is corroborated as to the circumstances of the offense and the participation of the accused. It is provided by the N. Y. Code Crim. Proc., § 399, that a conviction cannot be had upon the testimony of an accomplice unless he be corroborated by such other evidence as tends to connect the defendant with the commission of the crime. This statute has been adopted in many of the States of the Union.

Accoramboni, Vittoria, äk-o-räm-bō'nē, vit-ō'rē-a, an Italian lady famous for her beauty and her wild tragic history: date of birth unknown; d. 22 Dec. 1585. Her contemporaries thought her the most fascinating woman ever in Italy. Paolo Giordano Orsini, Duke of Bracciano, who was believed to have murdered his wife with his own hand, sought hers with her passionate acquiescence; but her father gave her to Francesco Peretti, nephew of Cardinal Montalto and living in his house. Peretti was assassinated 1581; and Vittoria fled to Bracciano; the scandal was great, and Gregory XIII. imprisoned her nearly a year in the castle of St. Angelo, but she married the duke as soon as released. Montalto becoming Pope as Sixtus V., the couple took refuge in Venetian territory. After a few months' residence at Salo on Lake Garda, the duke died, leaving her almost the whole of his great fortune; but an incensed relative of his, Ludovico Orsini, had her murdered at Padua, whither she had removed. This recital, valid on the evidence accessible up to now, and accepted by Gnoli in his «Life» of her (Florence 1870), leaves Vittoria much on the level of other passionate Italian women of her age; but the Countess Martinengo-Cesaresco has recently re-examined the evidence in her ‹Lombard Studies,› and thinks her innocent of complicity in crime. Much literary use has been made of her story, and Webster's play ‹The White Devil› is based on it.

Accord and Satisfaction signifies a satisfaction agreed upon between the party injured and the party injuring, which when performed is a bar to all actions upon this account. It must be legal. An agreement to stifle a criminal prosecution for a criminal offense such as an assault and imprisonment is void. (2 Wils. 241; 5 East. 294.)

Where a release is given to one of two joint tort-feasors which recites the receipt from him of a certain sum as full payment, it will operate as a bar to an action against the other tort-feasor. (136 Mass. 503.)

Accord with satisfaction, when completed, has two effects: it is a payment of the debt; and it is a species of sale of the thing given by the debtor to the creditor in satisfaction; but it

differs from it in this, that it is not valid until the delivery of the article, and there is no warranty of the thing thus sold, except perhaps the title; for in regard to this it cannot be doubted that if the debtor gave, on an accord and satisfaction, the goods of another, there would be no satisfaction. But the intention of the parties is of the utmost consequence. (30 Vt. 424.)

Accordion, a musical instrument in the form of a small box, generally from 8 to 12 in. long by 4 wide, and containing a number of metallic reeds fixed at one extremity, but left to vibrate freely. A small bellows, formed by a folding apparatus which unites the top and bottom of the box, supplies the wind, which, admitted by keys acting on valves, sets the reeds in vibration. In the harmonium (q.v.) and the American cabinet-organ the same principle is also employed. The accordion was introduced into America from Germany about 1828, but the principle has long been known in China, and employed for instruments played by the breath. The concertina, flutina, and organ-accordion are improvements.

Account, a register of pecuniary transactions, whether for personal use, to satisfy a contract, in obedience to law, or as a bill of items sent to a customer who buys on credit. A mutual account is one where debtor and creditor items are opposed between two parties. An open account, or account current, in commerce is one in which the balance has not been struck; in banking, one that may be added to or drawn upon at any time, as opposed to a deposit account, where notice is required for withdrawals. To keep an open account is to keep such a one running on, instead of closing it. A stated account is one which all parties have expressly or by implication (as by the debtor's retaining it beyond a reasonable time without objection) admitted to be correct. To open an account is to begin pecuniary transactions with a banker or merchant.

In law, an account is a detailed statement of the mutual demands in the nature of debt and credit between parties, arising out of contracts or some fiduciary relations. (32 Pa. St. 202; 1 Metc. (Mass.) 216.)

An open account is one in which some term of the contract is not settled by the parties, whether the account consists of one item or many. (1 Ala. N.S. 62.)

In equity, jurisdiction concurrent with courts of law is taken over matters of account (9 Johns. (N. Y.) 470; 1 Paige Ch. (N. Y.) 41) on three grounds: mutual accounts; dealings so complicated that they cannot be adjusted in a court of law; and the existence of a fiduciary relation between the parties.

Accountant, properly any one who keeps accounts, and till lately applied in the United States to all bookkeepers without distinction; more generally now restricted to the head bookkeepers of large houses or corporations, with difficult or complex accounts calling for expert ability. Especially an «expert accountant» or «public accountant» is understood as one not in the employ of any one house, but hiring his services out to such firms or companies, banks, or public institutions, as either find their accounts in disorder or wish a legal verification or a guaranteed statement for the public; or report on bankrupt estates under legal process. Few large financial institutions neglect to support public confidence by having their books periodically investigated and reported upon by an accountant unconnected with the concern. This is gradually building up, through many scandals and frauds upon the public, a much higher standard of professional duty among these experts: it is recognized that it is their duty not merely to certify to the correct balancing of the figures submitted to them, but to use reasonable intelligence and honorable purpose on the manner in which those figures were made, and whether they represent facts or gross fictions to deceive outsiders and lure in money to be mishandled. The proper, and in the United States the only, business of an accountant is to examine accounts and make out balance-sheets and statements. In England they assume a still further duty, that of managing estates and legacies.

Accretion, the increase of real estate by the addition of portions of soil, by gradual deposition through the operation of natural causes, to that already in possession of the owner. If an island in a non-navigable stream results from accretion, it belongs to the owner of the bank on the same side of the *filum aquæ*. (2 Washburn, Real Prop. 452; 3 Kent, Comm. 328; 6 Cow. (N. Y.) 537.) In some cases it has been held that it makes no difference whether the stream is navigable or not (24 How. (U. S.) 41; 10 Pet. 662) where the owner of land has received accretions thereto. The term «alluvion» is applied to the deposit itself, while «accretion» denotes the act.

Accrington, a manufacturing town and municipal borough of England, in Lancashire, on the Hyndburn, 20 m. N. of Manchester and 5 m. E. of Blackburn; on the Lancashire & Y. Ry.; inc. 1878. It is well laid out, and has various handsome buildings, including the town-hall, a splendid market hall, technical school and school of art, clubs, etc. The manufacture and printing of cottons, chemical works for their use, and the manufacture of spinning and other machinery, are the chief industries. Coal is wrought extensively. Pop. (1841) under 9,000; (1881) 31,435; (1901) 43,095. Accrington gives name to a parliamentary division of the county; pop. 84,878.

Ac'cum, Friedrich, frĕd'riн, German chemist: b. Bückeburg, 1769; d. Berlin, 1838. Removing to London at 24, eight years later he was made professor of chemistry and mineralogy at the Surrey Institution. He published several text-books on these sciences, but is remembered mainly for being (with an energetic print-seller, Ackermann) the introducer of gas-lighting into England. His ‹Practical Treatise on Gaslight› appeared in 1815. Another valuable service to society was his ‹Treatise on Adulterations of Food and Culinary Poisons› (1820). As the result of charges against his honesty he returned to Germany, and in 1822 was made professor in the Industrial Institute and Academy of Architecture in Berlin.

Accumulator, a device for the storage of energy, more particularly when the energy is supplied from an intermittent source, or when it is to be withdrawn intermittently or irregularly. The fly-wheel on a steam-engine is a device of

this sort, but it is not commonly referred to as an accumulator. The word is practically restricted to the following two senses: (1) a storage-battery (q.v.); (2) a hydraulic apparatus, commonly consisting of a plunger which is fitted to a vertical cylinder and heavily loaded with weights. Water is forced into the cylinder by pumps, with the result that the plunger and its weights are raised, and a considerable quantity of water is thus stored in the cylinder under a high pressure. By the use of such an accumulator it is possible to deliver water for a short time in far greater volume than the pumps feeding the accumulator could deliver it, and yet at the maximum pressure that the pumps are capable of producing. Hydraulic accumulators are used in connection with riveting-machines, cranes, and many other heavy tools.

Accusative Case, in Latin,— and thence applied to the corresponding case in Greek and other declensions,— that case of the noun, pronoun, etc., which designates the object to which the action of a verb is immediately directed. It corresponds with what, although the English noun is nearly without declension, is called in English the objective case. See DECLENSION.

Aceldama, a-sel'da-ma, a cemetery in Jerusalem used to bury strangers in. The traditional site is on a small plateau half-way up the southern slope of the valley of Hinnom, near its junction with the valley of Jehoshaphat; and it was certainly used in the 6th century for the burial of Christian pilgrims, and continued in use till the 17th. According to Matt. xxvii. 7, 8 it was bought by the chief priests and elders for a burial-ground, with the 30 pieces of silver returned by Judas after the betrayal; according to Acts i. 19 it was bought by Judas himself with the money, which he did not return, and his bowels burst open in it; according to both, the name means « the field of blood,» and it was a potter's. But as the Greek text gives a form « *Aceldamach,*» which would mean « field of sleep,» a natural and beautiful term for a burying-ground, and as according to Jer. xviii. 2 and xix. 2 there was a potter's in the valley of Hinnom, it would seem that the use and name of the place were very old at the time of Christ, and that the meaning « field of blood » was a misunderstanding, or a play on the real meaning, and its connection with Judas artificial. (History and description by Schick, 1892, quarterly statement of the Palestine Exploration Fund, pp. 283–9.)

Aceph'ali (« headless »), in civil history, certain levelers, in the reign of Henry I. of England, who acknowledged no head or emperor; or, according to another explanation, who were too poor to own any property, and so have any legal superior.

In Church history: (1) Bishops exempt from the jurisdiction and discipline of a patriarch. (2) Clergy belonging to no diocese. (3) Those who, on occasion of a dispute in the Council of Ephesus, A.D. 431, refused to follow either John of Antioch or Cyril of Alexandria. (4) Those who rejected the decision of the Council of Chalcedon, 451, on the nature of Christ. (5) In the 5th and 6th centuries, a large section of the followers of the Monophysite, Peter Mongus, who cast him off as their leader because of his accepting a peaceful formula called the Henoticon (q.v.). They soon afterward split into three parties, the Anthropomorphites, the Barsanuphites, and the Essianists, who again gave origin to other sects. (6) The Flagellants (q.v.).

Aceph'alocyst' («headless cyst»), a growth found in the liver, kidneys, and other glandular organs of man and oftentimes those of the lower animals. See TÆNIA.

Acer. See MAPLE; WHISTLEWOOD.

Aceratherium, ā-sĕ-ra-thē'ri-um, an extinct rhinoceros which inhabited Europe during the Miocene epoch. It had no distinct horn, whence the name (Gr. ἀ- without, κέρας horn, θήρ animal), but a small boss on the top of the skull indicates a rudimentary horn or callosity. American fossil hornless rhinoceroses formerly referred to this genus are now distinguished as Cænopus (q.v.).

Acerbi, Giuseppe, ä-chĕr'-bē, ju-sep'-a, Italian traveler and scientist: b. near Mantua, 3 May 1773; d. there August 1846. He studied at Mantua, devoting himself to natural science; in 1798 journeyed through Scandinavia, Finland, and Lapland, and in 1799 visited the North Cape, the first Italian ever there. On his return he stayed some time in England and published his « Travels » in English, later having them translated into French and German. He rendered great service to Italian literature by starting in 1816 the *Biblioteca Italiana*, which fought the Accademia della Crusca (q.v.). Made Austrian consul-general to Egypt in 1826, he contributed valuable articles on Egypt to the *Biblioteca*, and obtained many Oriental objects of interest to European museums. From 1836 till his death he lived at his native place.

Acerra, a-cherr'a, Italy (the ancient ACERRÆ, admitted to Roman citizenship 332 B.C., plundered and burnt by Hannibal): an episcopal city 9 m. N.E. of Naples, with which it is connected by railroad, and opposite Mt. Somma. It has a cathedral. The inundations of the neighboring Agno formerly made it very unhealthy, but the marshes are now drained. Pop. (1891) 13,633; (1901) 16,443.

Aces'tes, or **Æges'tus,** in Greek legend, son of Crinisus and Ægesta, and king of the country near Drepanum, in Sicily. He assisted Priam in the Trojan war, entertained Æneas during his voyage, and helped him to bury his father on Mount Eryx. In commemoration of this Æneas built a city there and called it Acesta.

Acetal. (1) A colorless, pleasant-smelling liquid, formed as a by-product in the preparation of aldehyde from alcohol, and occurring naturally in crude alcohol. Its formula is $CH_3.CH(OC_2H_5)_2$. It boils at 219° F. under ordinary atmospheric pressure. Its specific gravity is about 0.831, and its critical temperature is 490° F. Acetal mixes in all proportions with alcohol and ether. It is soluble in eighteen volumes of water at 80° F., and is more soluble at higher temperatures.

(2) « Acetal » is also used to signify any one of a group of compounds formed by the combination of one molecule of an aldehyde with two molecules of an alcohol, and the elimination of one molecule of water. They are obtained as by-products in the preparation of aldehydes from alcohols, a certain portion of the aldehyde formed combining with the unmodified alcohol.

Ac'etan'ilide (known in the drug trade as antifebrin), a crystalline compound obtained by the action of glacial acetic acid upon aniline (q.v.). Its formula is $C_6H_5NHCOCH_3$. It melts at 237° F., and boils at 563° F. without decomposition. It is readily soluble in alcohol and ether, and dissolves in hot water, but is only sparingly soluble in cold water. It is given in medicine as a sedative and febrifuge. Its physiological action is similar to that of antipyrin, but its administration is considered to be safer.

Ac'etates, compounds of acetic acid with metals or organic radicals. See ACETIC ACID.

Ace'tic Acid, an organic acid belonging in the fatty series, important on account both of its extensive use in the arts, and of its properties as viewed from the standpoint of the theoretical chemist. Its formula is CH_3COOH, or $C_2H_3O.OH$. It is a monobasic acid, the hydrogen in the radical CH_3 not being replaceable by a metal or another radical. In its dilute state it has been known for centuries as vinegar, and in strong vinegar the characteristic odor of the acid is quite marked. It may be formed by the oxidation, decomposition, and destructive distillation of many organic bodies. It is produced, as in the manufacture of cider vinegar, by the action of the microscopic plant *Mycoderma aceti,* better known as « mother-of-vinegar,» upon weak alcohol. In the manufacture of vinegar the alcohol required for the transformation is present in the cider as the result of a preliminary alcoholic fermentation. It has been shown that « mother-of-vinegar » has no effect upon pure alcohol, the reason for this being that a certain amount of albuminous and mineral matter must be present to serve as food for the plant. The greater part of the acetic acid of commerce is obtained by the destructive distillation of wood, acetate of lime being a by-product in the manufacture of wood-alcohol. (See WOOD-ALCOHOL, under ALCOHOL). The acetate of lime so obtained may be decomposed by the addition of sulphuric acid, when acetic acid is liberated, or it may be treated in any one of a number of other ways for the recovery of the acetic acid. One of the best methods consists in mixing the commercial acetate of lime with calcium chloride, and concentrating the solution until the compound known as calcium aceto-chloride ($CaC_2H_3O_2Cl.5H_2O$) crystallizes out. The crystals so formed are then dissolved in water, the solution is filtered through animal charcoal, more calcium chloride is added, and the operation is repeated to obtain a new crop of purer crystals. These crystals are finally distilled with moderately strong sulphuric acid, when a very pure acetic acid is given off.

By heating acetate of sodium with concentrated sulphuric acid it is possible to obtain acetic acid in a state free from water. The acid so obtained is a colorless liquid boiling at 244° F., and solidifying, at about 63° F., into an ice-like mass; from this property the anhydrous acid has been called *glacial* acetic acid.

Acetic acid is uninflammable in its liquid state, but its vapor burns with a fine blue flame. It is used as a solvent for organic substances, being a useful substitute for alcohol in certain cases on account of its relative cheapness.

Lead acetate (or sugar of lead) and copper acetate (or verdigris) are the most important compounds of acetic acid with the heavy metals. Aluminum acetate and the iron acetates are much used in dyeing. The acetates of lead, potassium, and ammonia are also largely used in medicine.

Acetic acid may be formed synthetically by exposing a mixture of one volume of acetylene (q.v.) and two volumes of air to daylight, in the presence of a weak solution of caustic potash. The acetylene is slowly oxidized, combining simultaneously with the caustic potash to form acetate of potash, according to the formula

$$\underset{\text{Acetylene}}{C_2H_2} + O + \underset{\text{Caustic potash}}{KOH} = \underset{\text{Acetate of potash}}{CH_3.COOK}$$

From the acetate of potash so formed the acetic acid can readily be obtained. This mode of formation is of no practical value, but it has a theoretical interest.

The relations of acetic acid with the organic radicals are too numerous and complicated to receive general treatment in the present article. The more important ones are noticed elsewhere. see ALDEHYDE; ALCOHOL; ETHER; etc.

Acetic Ether, or **Ethyl Acetate,** a colorless, inflammable liquid having the formula $CH_3.COO.C_2H_5$, or $C_4H_8O_2$, prepared by the action of sulphuric acid upon a mixture of alcohol and acetic acid. It has a specific gravity of about 0.91 and a specific heat of 0.48, and boils at 171° F., under the ordinary atmospheric pressure. It mixes readily with alcohol and with ether, and at ordinary temperatures is soluble in about 17 parts of water. See ESTERS; ETHER.

Ac'etin, a substance resembling fat in its constitution, obtained by acting upon glycerin with glacial acetic acid. Acetins are known as monoacetin, diacetin, and triacetin, according as the acetic acid has displaced one, two, or three of the hydroxyl molecules in the glycerin. The formula of monoacetin is $C_3H_5(OH)_2(OC_2H_3O)$; of diacetin, $C_3H_5(OH)(OC_2H_3O)_2$; of triacetin, $C_3H_5(OC_2H_3O)_3$.

Ace'to-ace'tic Acid, a thick acid liquid, having the formula $CH_3.CO.CH_2.COOH$. At 212° F. it splits up into carbon dioxide and acetone.

Ac'etone. (1) A limpid, mobile liquid with a taste suggestive of peppermint. Formula, $CH_3.CO.CH_3$. It occurs in crude wood-alcohol, from which it can be separated by distilling over calcium chloride. It is also obtained by the destructive distillation of acetates, notably those of barium and lead.

It occurs in the urine, blood, and brain of calcium diabetic patients. Lieben's test for acetone in the urine is as follows: Distilled urine is made alkaline by caustic potash, and a few drops of a solution of iodine and iodide of potassium are added. If acetone is present a yellow precipitate of iodoform is formed at once; if alcohol be present in the distillate, the same reaction takes place, but more slowly; but with acetone the reaction is immediate.

Acetone is very inflammable, and burns with a white smokeless flame. It boils at 133° F. at

ordinary atmospheric pressure; its specific gravity at ordinary temperatures is 0.800.

(2) Any one of a certain class of carbon compounds in which two alcoholic radicals are united by the group CO. These compounds are now called ketones (q.v.), to distinguish them from the particular member of the group defined in (1), above.

Ac'etoni'trile, a colorless liquid with a pleasant ethereal odor, and burning with a reddish-bordered flame. It has the formula C_2H_3N, and is isomeric with methyl cyanide. It is best prepared by distilling a mixture of potassium cyanide and potassium-methyl-sulphate. It boils at 178° F. at ordinary atmospheric pressure, and has a specific gravity of 0.79. It mixes with alcohol and water.

Ac'etyl, the radical of acetic acid, its formula being $CH_3.CO$. Acetic acid may be regarded as the hydrate of this radical, its formula being $CH_3.COOH$. Acetyl chloride, $CH_3.COCl$, is obtained by the action of phosphorustrichloride upon acetic acid. Acetyl chloride evolves hydrochloric acid when it is heated with any substance containing the radicals hydroxyl, amidogen, or imidogen, and hence it is of importance as a test for these substances.

Acet'ylene, a hydrocarbon gas, C_2H_2, commercially prepared by adding water to calcium carbide, when both decompose and recombine into acetylene and slaked lime. It was discovered in 1836 by Edmund Davy, when experimentally trying water on the impure carbide produced by distilling calcined potassium tartrate to obtain potassium; named by Berthelot, who in 1862 prepared it by red-heating ethylene, by electrically vaporizing carbon, and by incomplete combustion of coal-gas; the same year Wöhler produced the carbide by heating carbon with an alloy of calcium and zinc. Acetylene is also produced by the direct union of carbon and hydrogen when an electric arc is caused to pass between carbon terminals in an atmosphere of hydrogen. But both carbide and gas were laboratory curios till after 1892, when a new method of obtaining cheap carbide was accidentally discovered at the works of Thos. L. Willson, a Canadian, at Spray, N. C., and perfected by the chemist Dr. G. de Chalmot and the electrician J. M. Morehead; and not long afterward Prof. Henri Moissan of Paris independently discovered the same in essence,— the electric arc acting on mixed lime and carbon. This at once made the gas of great industrial importance for lighting, and the carbide as an agricultural germicide.

Acetylene is a colorless gas of an agreeable ether-like odor; but the impurities of commercial carbide give it often a garlicky smell. It is much less poisonous than coal-gas or water-gas, and practically harmless. It is .92 the weight of air, so that a 10-foot cube weighs upwards of 75 lbs. It takes fire at 896° F., and in the open air burns very smokily, with clouds of soot; but when consumed in a suitable burner, with a sufficient supply of air, it gives the whitest and clearest light of any common illuminant, the final products of its combustion being carbon dioxide and water vapor, with no trace of the poisonous carbon monoxide. At 1200° it changes to isomeric hydrocarbons, yielding benzene (C_6H_6) and tar; at 1400° it decomposes into its elements. It gives off much greater heat in combustion, volume for volume, than coal-gas; but light for light it gives off much less, owing to its vastly greater illuminating power and consequently much smaller volume to equal light. Mixtures of air and acetylene containing from 2.8 to 65 per cent of the gas are inflammable in the open, but in tubes the possibility of combustion striking through decreases with their diameter until it ceases at about one fifth of an inch.

Pure acetylene is sometimes objected to because the small dazzling point of light strains the eye unless hidden, and the black shadows diminish the real illuminating power. Various diluents have been tried; the only ones in practical service are oil-gas, which is used on all the Prussian government railroad lines, mixed with 20 per cent of acetylene under 10 atmospheres pressure; and air, which in the best burners (the Napheys, a Philadelphia invention of the Bunsen order) is thoroughly mixed with acetylene to secure perfect combustion and the best illumination. Prof. Vivian B. Lewes of England thinks methane or marsh gas by far the best; it is too costly by itself, but can be generated along with water gas so as to give a cheap mixture which a little acetylene enriches into a powerful light.

When added to coal-gas or water-gas in small proportions (5 per cent or so) acetylene does not increase the illuminating power of the mixture nearly as much as might be expected. When added in considerable proportions it becomes a most valuable enricher of coal-gas; but so is coal, and even the low cost of that is grudged.

Storage.— It has been desired to use the gas without the cost and trouble of installing and operating generators; and the two possible methods are to liquefy it and make a solution of it. The former has been done by a pressure of 39.76 atmospheres at 68°, making a liquid .33 the weight of water and 1-500 the volume of the gas; a jet allowed to escape evaporates so fast that the resultant cold of — 130° F. freezes part of the liquid to a white solid. It is shipped in steel cylinders containing 9 lbs. liquid, or ½ cu. ft., giving 250 feet of gas, equal to 3,000 feet of good coal-gas or some 6,000 of such as many cities give.

Frequent explosions of these, however, have caused insurance companies to put them under ban. According to some authorities these explosions have invariably been due to gross carelessness; but according to others, acetylene gas, when stored in the compressed state, is liable to explosive spontaneous decomposition. This last view may very possibly be correct, since acetylene, like nitro-glycerine, is an endothermic substance; that is, its formation directly from carbon and hydrogen is attended by the absorption of heat. These objections do not apply to acetylene, except when it is stored in considerable quantity or under a considerable pressure. Acetylene is usually produced as fast as it is consumed, so as to avoid storage so far as possible; but where this is impracticable it is much safer to keep the acetylene in solution than to store it in any quantity. At 68° F. water dissolves 1.1 its volume of acetylene, alcohol 6, acetone (q.v.) 15, or at 12 atmospheres 300;

besides, a rise of temperature makes much less increase of pressure within the vessel than with the liquid acetylene, and hence lessens the danger of storage and transportation. The acetone solution, also, cannot be exploded, which is the great public bugbear against acetylene.

Generators.— Prof. Lewes divides acetylene generators into four types: (1) where water drips on a mass of carbide (as in ordinary bicycle lamps); (2) where it rises against a basket of carbide in a bell, or (3) against layers of it in trays without a bell; (4) where carbide drops slowly into excess of water. The first two are liable to overheat, decomposing part of the acetylene, losing that much and spoiling the burners with tar; the third is better, the fourth best of all.

For small lamps acetylene is nearly confined to bicycles, where water is dropped on a heap of carbide; they are too small to be in danger from overheating, but are costly to use because the carbide remaining after each lighting is too mixed with refuse to use again. Household lamps are sold, but are not yet in favor.

The popular books on chemistry state that acetylene combines with copper, forming a compound which readily undergoes explosive decomposition; but in order to obtain this compound it is necessary to pass the gas into an ammoniacal solution of cuprous chloride. A red precipitate of cuprous acetylide, having the formula $C_2H_2Cu_2O$, is then formed, and this precipitate explodes violently upon percussion. A similar compound of silver is known. Acetylene will not directly attack any of the common metals or alloys, and hence the current fear of its being charged with explosive copper salts under the conditions of ordinary practice has no warrant.

Its commercial future belongs to the domain of prophecy, not of statistical fact. In theory a manufactured product like carbide cannot compete with a cheap native product like soft coal; and improvements in burners and cheap water-gas should greatly increase light and reduce cost.

On the other hand, the relatively enormous illuminating power of acetylene largely offsets the cost of the raw material. The use of acetylene for practical illumination is certainly extending, and the immense output of calcium carbide (q.v.) must find a market.

Achæa. See ACHAIA.

Achæi, ak-ī'ē, **Achaians,** ak-ā-yans, or **Achæans,** ak-e'ans, the descendants of the mythical Achæus, son of Xuthus and grandson of Helen; a generic term employed by Homer to designate the whole Hellenic host before Troy, and in poetic use applied to all the Greeks indiscriminately. They appear to have been that branch of the Greeks which inhabited southeastern Thessaly and northern Peloponnesus, and by the Dorian invasion were driven altogether beyond the Corinthian Gulf and cooped into a strip of Peloponnesus along its southern shore, where they were the nucleus of the later Achaian League. See ACHAIA.

Achæmenidæ, ak'ē-men'i-dē, the Greek name of the Persian dynasty (558–330 B.C.) founded by Cyrus the Great, including Cambyses, Darius I. and II., Xerxes, Artaxerxes, etc., and ended by Alexander the Great. The family took its name from an ancestor of Cyrus, found in Persian inscriptions as Haxamanisya, which the Greeks softened to Achæmenes (a-kē'men-ēz).

Achaia, ak-ā'ya, or **Achæa,** ak-ē'a, in Homer, southeastern Thessaly, where was Phthia, the home of Achilles. In later history, a strip of Peloponnesus along the southern shore of the Corinthian Gulf, rising from the coast to wooded hills abounding in beasts of the chase; the uplands were fertile with grapes, olives, and other fruits. The nome called Achaia (including Elis) in the modern Greek kingdom, the northwestern part of Morea with capital at Patras, is still so, except along the west coast, on the Ionian Sea. When it first appears in authentic history (Herodotus), it is a confederacy of twelve towns — Pellene, Ægeira, Ægæ, Bura, Helice, Ægium, Rhypes, Patræ, Pharæ, Olenus, Dyme, and Tritæa — headed by Helice, and keeping much to itself in Greek affairs. Helice was destroyed by an earthquake and swallowed by the waves 373 B.C., and Ægium succeeded to the hegemony; and at some time unknown Olenus was deserted.

The League took no share in the Peloponnesian war, but the Macedonian supremacy and the dynastic struggles after Alexander's death broke it up altogether. Some of the remaining ten towns were held by Macedonian garrisons, some by local tyrants; a state of disunion equally gratifying to Macedonia and intolerable to Greek patriots. In 280, when several kings were dead, Macedonia in confusion, and the great Pyrrhus absent in Italy, Patræ and Dyme, the two westernmost towns, formed an alliance; Tritæa and Pharæ joined them: and the new Achaian League, famous in history, which gave southern central Greece more than a century of order and good government, was begun. The cities probably drove out their garrisons or rulers, as later ones certainly did. Five years afterward Ægium expelled its garrison and joined the League; Bura was freed and its tyrant slain by its people and their exiled brethren, and joined also; and Iseas, tyrant of Ceryneia, seeing how events were trending, voluntarily surrendered his position with a guaranty of safety, and annexed the city to the League. Seven towns were now included; and the other three were recovered and annexed not long after. But all were small and poor; fortunately for the League, as it was thought too insignificant to molest, and grew up peacefully and solidly for some 30 years. The chief name in its early history is Markos of Ceryneia, who helped liberate Bura even before his own city was freed, and seems to have been the Washington of the League. But its first entrance into the rôle of a great Greek political force began with the expulsion in 249 of the tyrant of Sicyon by Aratus of that city, who induced it to join the League; it not only gained thereby the first city outside the old Achaian confederacy, and became more or less Pan-Greek, but gained Aratus, its second founder, and a statesman and administrator of high order, though his jealousy of other leaders and his military incompetency injured it deeply. A still greater accession came in 242, when Corinth expelled its Macedonian garrison and joined; and in 234 Lydiadas, tyrant of Megalopolis, the powerful city founded by Epaminondas, volun-

tarily resigned his place like Iseas and brought in his city, being made commander-in-chief of the League's army the next year. Before the century had begun its last quarter the League included all northern and central Peloponnesus, and many towns elsewhere.

The League was a federal union of absolutely independent States, each having equal power in the Council, which met twice a year — at first and for a long time in a grove near Ægium, but later, at Philopœmen's motion, in the League cities in rotation. The vote of each city was given as a unit, not by elected delegates, but by any of its citizens who were present, any one over 30 having a right to be so; attendance therefore naturally fell to the richer citizens with means and leisure, and the assembly was a rough representative body of the leading men. The union acted as a unit in foreign affairs, and there was a secretary to record the debates and resolutions. The head officer was the *strategos*, who was commander-in-chief and civil president at once; he had under him a *hipparchos* (cavalry commander) and *nauarchos* (admiral), and a board of ten *demiourgoi* as assistants in the Council.

The League of course had its internal feuds and discordances of policy; and the Ætolian League north of the Gulf (only half Greek, and wholly barbarian in instability and lack of pro-Greek feeling), which alternately allied itself with it and ravaged its territory, was a mischievous rival and enemy. But the League would probably have fully held its own till the Romans came, but for Sparta. Cleomenes II. had revolutionized that State, which had shrunk into the narrowest of oligarchies and could not maintain its position; he had turned it into a socialistic one, and wished to force the League to join him in a great Peloponnesian union, of which Sparta would be master, imposing both its foreign policy and perhaps its internal organization on the rest, and which would destroy the internal independence of the League and menace the possessions of every property-holder in it. The League was badly defeated by Cleomenes in the field, and was between hammer and anvil; for the only power which could save it was Macedonia, its natural foe and old master, and Antigonus Doson refused to give aid unless the citadel of Corinth, the key of Peloponnesus, held by the League, were given up to him. Aratus felt, however, that the suzerainty of Macedonia, now that the League was strong enough to prevent active tyranny, was a less evil than the mastery of Cleomenes; and by cunning management he induced the League to pay the price asked for Antigonus' help. Cleomenes was crushed at Sellasia, and his Spartan constitution came to an end, and the League became a dependency of Macedonia. Yet Aratus' policy was justified by events so far as the League was concerned: it did not suffer from Macedonian tyranny, though the chance of forming a united Greece was at an end. But that was probably as little possible under Cleomenes as under Macedonia.

In point of fact the destroying enemy was not Macedonia but Rome. Under the noble and able Philopœmen of Megalopolis, soldier and statesman of high rank, the League was prospering and giving the citizens an enviable government. But a pro-Roman policy prevailed, and Philopœmen left the country. In 198 it allied itself with Rome against Macedonia, and this was always the beginning of the end with the other party to a Roman alliance. There were wars against Sparta, and a struggle between Roman and anti-Roman partisans in the assembly, with Roman envoys and intriguers to fan the flames. Finally, in 167, the Romans deported the flower of the Achaian citizens to Italy, many of them being imprisoned, others — as the future historian Polybius (q.v.), then a youth of 18 — kept as hostages but given Roman advantages. The last struggle took place in 146, when Mummius defeated the League at Corinth, and the independence of Greece or any fraction of it was at an end. All southern and central Greece was made a Roman province called Achaia.

(The first-hand authority for the League is Polybius, unfortunately extant only in fragments: in some parts he is pieced out by Livy, passages of whose work are often obvious translations from Polybius. In English the one great work is E. A. Freeman's unfinished ‹History of Federal Government,› nearly all devoted to the Achaian League; London, 1863; reissued with a fragment on Federalism in Italy.)

Achaqua, ä-chä'kwa, a South American Indian tribe probably extinct, though a few hundreds, who lived in the upper Orinoco forests in northeastern Colombia, were still existent in 1850. They were utter savages, practising infanticide beyond the second child, polyandry, and tattooing.

Achard, Franz Karl, äн'art, fränts karl, German chemist and physicist: b. Berlin 28 April 1753; d. 1821. He published in 1780 the results of many and careful experiments on the adhesion of bodies. But later he devoted himself to the development of the beet-sugar manufacture, and after six years of laborious endeavor discovered the true method of separating the sugar from the plant. His process was of enormous service to the countries whom the Napoleonic blockade shut off from the West India sugars. He was afterward director of the class of physics in the Academy of Science in Berlin.

Achard, Louis Amédée Eugène, ăsh-ar, loo-ē am-ā-dā ė-zhān, French novelist: b. April 1814; d. 25 March 1875. Originally a merchant, he became a contributor to several Paris journals in 1838. After the revolution of 1848 he was active as a royalist political writer; 1848–72 the *Revue des Deux Mondes* brought out almost annually a new story from his pen. He depicts pre-eminently conflicts in family life and society. ‹Parisian Letters,› published in 1838 under the pseudonym of «Grimm,» made his reputation. Other works of his are: ‹Belle Rose› (1847), ‹The Royal Chase› (1849–50), ‹Castles in Spain› (1854), ‹The Shirt of Nessus› (1855), ‹Chains of Iron› (1867), ‹The Viper› (1874).

Acharnæ, a-kar'nē, a large town of Attica, where the Thirty Tyrants (q.v.) encamped when they marched against Thrasybulus; and where the Lacedæmonians, under their king Archidamus, pitched their tents when they made an irruption into Attica at the beginning of the Peloponnesian war. Aristophanes, in his comedy ‹The Acharnians›— where a citizen of

the place, sick of war, ravage, and the stoppage of trade, makes a treaty of peace with the Lacedæmonians on his own account — represents the inhabitants as charcoal-makers; and other comic writers stigmatize them as rough and boorish.

Achates, in the Æneid, a friend of Æneas, whose fidelity is depicted as so exemplary that *fidus Achates* (the faithful Achates) has become a proverb.

Acheen. See ACHIN.

Achelous, ak-e-lō'us (now ASPROPOTAMO, «White River»), the largest river in Greece: 130 m. long, and not navigable. It rises on the Pindus range, flows south in a boisterous torrent, forming the boundary between Ætolia and Acarnania, and empties into the Ionian Sea opposite Ithaca. In its lower course it is an alluvial stream, winding in great loops through very fertile and marshy plains; it comes from the mountains heavily laden with fine white mud, which it deposits along its banks and in the sea at its mouth, where it has formed a number of small islands.

In Greek legend, the son of Oceanus and Terra, or Tethys, god of the river. As one of the numerous suitors of Dejanira, daughter of Œneus, Achelous entered the lists against Hercules, and, being inferior, changed himself into a serpent and afterward into an ox. Hercules broke off one of his horns, and Achelous, being defeated, retired into his bed of water. The broken horn was given to the goddess of plenty.

Achen, Johann («Hans») **von,** ä'Hen, yō'hän fon, or **Acken,** ä'ken, German painter: b. Cologne, 1512; d. 1615. He studied at home, and at Venice under Kaspar Rems, and took service with the Bavarian court 1590; later went to Prague at the invitation of Emperor Rudolph II. The Protestant church at Cologne contains his ‹Crucifixion,› the cathedral at Bonn his ‹Entombment,› and among his other works are ‹Christ Raising the Widow's Son,› and ‹Truth Victorious under Protection of Justice.›

Achenbach, Andreas, ä'Hen-bäH, German landscape and marine painter: b. Cassel, 1815. He studied under the eminent Schadow at Düsseldorf, and became one of the leading artists of that school. He painted in Holland, along the Rhine, and in Norway, producing landscapes of rich coloring and intense realism. He was made R.A. in Berlin, and knight of the Legion of Honor in France; and took a first medal in Paris, 1855. Private galleries in the United States have many of his finest works.

His younger brother OSWALD, b. Düsseldorf 1827; d. 1 Feb. 1905, was also a landscape artist, esteemed of more ideal quality than Andreas; and his pictures of Switzerland, Italy, etc., were largely bought in the United States.

Achene, Achenium, Akene, a-kēn', etc. («not gaping»), a dry, hard, one-seeded fruit in which the wrappings of the seed set closely to it, forming almost a coat. The entire family of *Compositæ* are of this sort: the «seeds» of borage, the sunflower, thistle, dandelion, etc. Sometimes they are grouped on a common receptacle, called an *etærio;* as in the strawberry, where it is fleshy, the achenes being the «pits,» or in the centre of the buttercup, where they form the «fruit»; sometimes they are inclosed in the fleshy tube of the calyx, as in the rose.

Achensee, ä'Hen-zā, a lake in N. Tyrol, Austria, 5½ m. long by ½ m. wide, 20 m. N.E. of Innsbruck. Its shores are of great beauty, and it is a noted summer resort, having many hotels and private villas, while steamers carry passengers to points of interest.

Achenwall, Gottfried, ä'Hen-väl, got'frēd, German statistician: b. Elbing, 20 Oct. 1719; d. Göttingen, 1 May 1772. He studied at Jena, Halle, and Leipzig, and became professor of philosophy, and later of law, at Göttingen. In economics he belongs to the school of «moderate mercantilists»; but it is in statistics that he holds a really high place. The work by which he is best known is his ‹Constitution of the Present Leading European States› (1752). In this he gives a comprehensive view of the constitutions of the various countries, describes the condition of their agriculture, manufactures, and commerce, and frequently supplies statistics in relation to these subjects. German economists claim for him the title of «Father of Statistics»; but English writers dispute this, asserting that it ignores the prior claims of Petty, and other earlier writers on the subject. He gave currency to the term *Staatswissenschaft* (politics), which he proposed should mean all the knowledge necessary to statecraft or statesmanship.

Acheron, ȧk'e-ron, the ancient name of several rivers in Greece and Italy, all connected by legend with the lower world. The principal was a river of Thesprotia in Epirus, which passes through Lake Acherusia, receives the Cocytus (Vuvó), and flows into the Ionian Sea south of the promontory of Chimerium, at Glycys Limen or Elæa, now Port Fanari. At one part its course lies between mountains rising precipitously to the height of 3,000 feet. The name is also given to a river of Elis, a tributary of the Alpheus, and to a small river of Bruttium, in Italy, near Pandosia (location uncertain), near which Alexander of Epirus fell in battle against the Lucanians and Bruttians (326 B.C.). Their legendary celebrity appears to have been originally due to the Acheron in Thesprotia. This country being regarded by the Greeks as the end of the world in the West, they supposed the entrance to the lower world to be here. As this district became better known, the legendary river was placed elsewhere, and finally transferred to the lower regions. In Homer, Acheron is represented as a river of Hades. According to later traditions a son of Helios and Gæa or Demeter, who bore this name, was changed into an infernal river as a punishment for giving drink to the Titans during their war with Zeus. The Etruscans are said to have worshipped Acheron. The name of Acheron was ultimately used in a poetic or figurative way to designate the whole of the lower world.

Acherontia Atropos. See DEATH'S HEAD MOTH.

À Cheval. See TACTICS.

Achillea. See YARROW.

Achilles, a-kil'ēz, one of the heroes of Greek mythology, and in particular the hero of Homer's Iliad. According to the latter he was the son of Peleus, king of the Myrmidons in Phthiotis, a district of Thessaly, and of the Nereid or sea-goddess Thetis, and the grandson

of Æacus; hence often called Peleides and Æacides. He was educated from childhood by Phœnix, a friend of his father, who accompanied him to the Trojan war; and Cheiron the centaur instructed him in the art of healing. Achilles went to this war with the knowledge that he was to perish in it; his mother having foretold him that he should either live a long and inglorious life, or die young after a glorious career. He led his troops, the Myrmidons, against Troy in 50 ships. During the first nine years of the war we have no minute detail of his actions; in the tenth a quarrel broke out between him and the general-in-chief, Agamemnon, which led him to withdraw entirely from the contest. In consequence the Trojans, who before scarcely ventured without their walls, now waged battle in the plain with various issue, till they reduced the Greeks to extreme distress. The Greek council of war sent its most influential members to soothe Achilles' anger, and induce him to return to arms, but without effect. Rage and grief caused by the death of his friend Patroclus, slain by Hector, induced Achilles to return to battle. Thetis procured from Hephæstus (Vulcan) a fresh suit of armor for her son, who at the close of a day of slaughter killed Hector and dragged him at his chariot wheels to the camp, but afterward gave the body to Priam, who came in person for it. Achilles then performed the funeral rites of Patroclus, with which the Iliad closes. It contains, however, several anticipative allusions to the death of Achilles, which is also mentioned in the Odyssey. He was killed in a battle at the Scæan Gate.

Here ends the history of Achilles so far as it is derived from Homer. By later authors a variety of fable is mixed up with it; some perhaps old legend, much certainly outright invention. To make him immortal, his mother during his infancy concealed him by night in fire, to destroy the mortal parts inherited from his father, and anointed him by day with ambrosia (the story of Demeter and Demophoön). His father discovering him one night in the fire, Thetis fled; and his father entrusted him to the care of Cheiron, who fed him with the hearts of lions and the marrow of bears, and gave him the education proper to a hero. According to another story Thetis made him invulnerable by dipping him in the Styx, but the heel by which she held him was untouched by the water; accordingly he received his fatal wound in the heel. The story of Siegfried is patterned on this. To prevent his going to Troy, where it was predicted he should perish, Thetis sent him, disguised as a girl, to the court of Lycomedes of Scyros. He was educated with Lycomedes' daughters, one of whom, Deidameia, became the mother of Pyrrhus or Neoptolemus by him. Odysseus (Ulysses) went to the court of Lycomedes to discover him and induce him to join the war, in which Calchas had declared his aid indispensable. He succeeded by a stratagem. Presenting himself as a merchant, he offered the daughters of Lycomedes female ornaments and articles of attire for sale, among which he laid a shield and spear. He then raised an alarm of danger, on which the girls fled, and Achilles seized the weapons. He is said to have been killed either by Apollo in the likeness of Paris, or by an arrow of Paris directed by Apollo. According to another account he made love to Polyxena, a daughter of Priam; and, induced by the promise of her hand on condition of his joining the Trojans, went unarmed to the temple of Apollo at Thymbra, and was there assassinated by Paris. Various stories are told of the relations of Achilles with Iphigenia (q.v.), who was brought to the camp at Aulis on pretext of being married to Achilles. In one account Achilles interferes to rescue her from being sacrificed, and sends her to Scythia; in another he marries her, and she becomes the mother of Pyrrhus. Others say he was united to her in the lower world, where he became a judge; others again say he married Medea in Elysium. Annual sacrifices were offered to Achilles by the Thessalians at Troas by command of the oracle of Dodona; at Olympia and other places in Greece sacred honors were likewise paid to him. This has led to the unsafe inference that he was originally an Achaian god; but remembering the propensity of uncivilized races to deify superior geniuses among them, and such cases as that of Roland, it is much more likely that he was a chief before he was a god. It is probable that a real Thessalian warrior existed who has been thus idealized, though we do not know his name or real deeds.

Achilles Tatius, a-kil'ēz tā'shi-us, a Greek writer of romances: b. in Alexandria; flourished in the 5th century of our era. Suidas says he was a Christian bishop, but this is doubted. He wrote ‹The Loves of Clitophon and Leucippe,› an erotic story in eight books, of pleasing but florid style, and without much regard to unity or consistency of plot; it was modeled on Heliodorus' ‹Ethiopica.› That the story was very popular in its day is proved by the number of copies of it that are still in MSS., and by the plentiful imitations of it in the Middle Ages. An English translation by Anthony Hodges was published in 1638.

Achilles Tendon, a tendon, so called because, as fable reports, Thetis, the mother of Achilles, held him by that part when she dipped him in the river Styx to make him invulnerable. It is the strong and powerful tendon of the heel, which is formed by the junction of divers muscles, and which extends from the calf to the heel. When this tendon is unfortunately cut or ruptured, as it may be in consequence of a violent exertion or spasm of the muscles of which it is a continuation, the use of the leg is immediately lost; and unless the part be afterward successfully united the patient will remain a cripple for life. The indications are to bring the ends of the divided parts together, and to keep them so until they have become firmly united. This tendon is frequently the seat of a synovitis, just above the heel, from excessive exercise.

Achimenes, a-kĭm'e-nēz (from the Greek name of an East Indian plant used in magic), a genus of tropical American plants of the order *Gesneraceæ*, greatly cultivated in greenhouses for the beauty of their red, white, and blue flowers, which, if the rhizomes are potted by the first of April, bloom from the last of May till into October or even November. It may also be propagated by cuttings. The species are numerous.

Achin, Acheen, or **Atcheen,** a-chēn′ (properly *Acheh,* Portuguese corruption *Achem,* Dutch *Atjeh* or *Ajeh*), a district at the N.W. extremity of Sumatra, till 1873 an independent sultanate, now a province of the Dutch Indies: area, 20,471 sq. m.; pop. (1897) stated at 531,705 (but a true census must be impossible). The surface is divided into an eastern and a western half by a mountain chain which traverses the whole island, rising in the peak of Abong-Abong to 11,000 feet. At the farthest north is the famous Gold Mountain, at the base of which lies the capital. On both sides are numerous stretches of level or undulating soil, watered by small but deep streams, and admirably adapted for tree-culture, gardening, and rice. The flora and fauna agree with those of Sumatra: pepper-trees and areca-nuts grow there. The natives employ themselves in agriculture, cattle-rearing, trade, fisheries, weaving cloth, and working in gold, silver, and iron. The chief agricultural industry is the production of rice and pepper, the latter sent from many small western ports. From Pedir and other northern ports large quantities of betel-nut are exported to India, Burmah, and China. Achin ponies are also much reputed and exported. Minor exports are sulphur, iron, sapan-wood, gutta-percha, dammer, rattans, bamboos, benzoin, and camphor, the latter highly valued in China and bringing an enormous price. Silk, once plentiful, has nearly disappeared. Nor is there now much export of the gold that once drew so much trade thither and made it so rich as to astonish foreigners. No place in the East save Japan was so abundantly supplied with it, and it was from far antiquity part of the Golden Chersonese. It exported probably 15,000 to 20,000 ounces a year. The imports are mainly rice (the native supply being insufficient), opium, salt, dried fish, cotton goods, iron and copper wares, firearms, pottery, etc. The people are distinct from the rest of the Sumatrans, who are Malays: they are taller, handsomer, and darker, more active and industrious, and good seamen; but they are treacherous, bloodthirsty, and revengeful, immoral, and inordinately addicted to opium. Their ethnological place is not settled; they are believed to be Malay at root, though probably with some admixture from India, and not impossibly an Arab strain. Their speech is said by some to be Polynesian at root, though with much Malay loan element. Their literature is entirely Malay, and comprises poetry, theology, and chronicles.

The capital of the province is Kota Radja or Achin, situated at the northwest extremity, on a stream navigable by boats, about 4½ miles from its port Oleh-leh, with which, since 1876, it has been connected by a railway. Formerly a large and flourishing city, it was almost entirely destroyed during the war, but is now beginning to revive. It contains a Dutch garrison of 2,000 men.

History.— Civilization was first introduced into Sumatra by Hindu missionaries in the 7th century, and a considerable amount of immigration from India followed. In the 13th century it was converted to Mohammedanism by Arabs — the sultans of Achin claim descent from the first Mohammedan missionary — and the Arabic alphabet displaced the Japanese. Northern Sumatra was visited by several European travelers in the Middle Ages, as Marco Polo, Friar Odorico, and Nicolo Conti; and some of these, as well as Asiatic writers, mention Lambri, a State which must have corresponded nearly with Achin: but the first to name it as such is Alvaro Tellez, a captain of the Portuguese Tristan d'Acunha's fleet, in 1506. It was then a dependency of Pedir adjoining; but within twenty years it had not only gained independence, but swallowed up all the other States of northern Sumatra. It attained the climax of power under Sultan Iskandar Muda, 1607–36, when it extended from Aru, opposite Malacca, round by the north to Padang on the western coast, a seaboard of 1,100 miles; and its supremacy was owned also by the large island of Nyas, and by the continental Malay States of Johór, Pahang, Quedah, and Perak. It is in fact the only Sumatran State which has at any time been powerful since the Cape route to the East was discovered. Its wealth astonished the European visitors and traders; and its great commercial repute is shown by the fact that it was to Achin port that the first Dutch (1599) and English (1602) commercial ventures were directed. Lancaster, the English commodore, carried letters from Queen Elizabeth to «the king of Atcheen.» James I. exchanged letters with Iskandar Muda in 1613, and the Achinese sent envoys to the Dutch republic, who were received by Prince Maurice in camp (1602). But native jealousy of foreigners and the latter's rivalry with and destruction of each other's ventures prevented the establishment of permanent factories there. Still, the trade, though spasmodically interrupted, was very important; foreign merchants of many nations were settled in Achin city port, while other Chinese merchants came annually and held a great fair through June and July. For 58 years after Iskandar's death the Malay oligarchy of chiefs placed females on the throne; in 1699 the Arab party suppressed this system and set up an Arab ruler, and the State rapidly decayed from internal factions. From 1666 on, the Dutch had held possessions around Padang on the western coast, and gradually gained much in old Achin; in 1811 the British seized this as well as the other Dutch East Indies. In 1816 Java was restored to the Dutch, but the English colonies insisted the more strenuously that English influence should be maintained in Achin; and in 1819 the Calcutta government made a treaty excluding all other foreigners from permanent settlements there. In 1824 an exchange was made with the Dutch, of the Sumatran settlements for others in Asia; the above article was not mentioned, but it was privately understood that it should not be insisted on if the Dutch would make no war on Achin. In the convention at The Hague, 2 Nov. 1871, the Dutch insisted on the latter stipulation being formally withdrawn, as the Achinese were pirates and chastisement was often needed: and in 1873 Holland — with plenty of provocation, but grave doubts even at home of its necessity — embarked in the war, which has cost it 15,000 lives and over $100,000,000, and has not yet ended in the real subjugation of the interior country. Achin city was captured and civil government has been instituted in the coast territory; but the natives are fierce and have a good country for guerrilla warfare, and English blockade-runners

keep them supplied with arms and ammunition. Many evidences of these wars may be seen in Holland. (The authoritative works are all in Dutch: the chief is Smouck's 'Die Ajehers,' 2 vols. Batavia 1893-5. There was also one of Veth, 'Atchin,' Leyden 1873.)

Achish, king of Gath in Philistia, with whom David takes refuge when out of favor with Saul; represented as a dull easy man, whom David dupes into believing that he is making war only on the Judahites and their allies, when in fact he is raiding the native tribes, and enriching his stronghold Ziklag with their plunder. His lords are not so blind, however, and make him dismiss David before going to battle at Mount Gilboa. David lived with him four months according to one account, a year and four months according to another.

Achromatism. Because the several components of a beam of ordinary light are of different refrangibilities, it follows that they are not brought to a common focus by a simple convex lens. The violet rays meet at a point nearer the lens than that at which the red rays unite, and the optical image is confused and fringed with prismatic colors.

This difficulty is greatest with lenses of short focus, whence the early practice of constructing telescopes of enormous length. Sir Isaac Newton, misled by a really remarkable series of petty accidents, concluded that this difficulty could not be obviated, and that large refracting telescopes were therefore impracticable. He therefore gave his attention to the development of the reflector.

In 1757, however, John Dollond, a Spitalfields weaver, discovered that different substances separate the colors of light, for a given mean refraction, to a different degree. He therefore constructed double lenses of two different kinds of glass,— crown glass and flint glass. A concave lens of flint glass brings the colors together while not entirely destroying the refraction caused by a convex lens of crown glass. The correction is far from perfect, however, and even the best telescope lenses produce a blue halo surrounding the stellar images. This outstanding color may be reduced by combinations of three or more lenses; but such devices greatly increase the mechanical difficulties of the optician. The present practice is to bring together such portions of the light as most powerfully effect the eye or the photographic plate, leaving the other tints uncorrected. The introduction of new kinds of glass, especially the Jena glass, so called, has somewhat improved the chromatic correction of smaller objectives. See DISPERSION; LENS; MICROSCOPE; TELESCOPE; LIGHT.

Achsharumov, Nikolei Dmitriyevich, äch-shä-roo'mōf, nē-kōlAI dmē-trē-yev'ich, Russian novelist and critic: b. St. Petersburg, 15 Dec. 1819; d. Moscow, 30 Aug. 1893. For a time he held a post in the ministry of war, but came later to devote himself to painting, and particularly to literature. He first attracted attention by a dramatic sketch, 'The Masked Ball,' and became more widely known through his novels, 'The Double'; 'The Gambler'; 'The False Name'; 'An Unusual Case'; 'The Mandarin'; and 'At All Costs' ('Was es auch Kosten mag'). His critical essays include studies of Tolstoi, Turgeniev, Dostoievski, and Herbert Spencer.

A Chula, ä-shoo'la (Port.), a dance resembling the fandango (q.v.).

Achurch, Janet, English actress: stage name of Janet Achurch Sharp, now Mrs. Charles Charrington: b. Lancashire; début at Olympic Theatre, January 1883. In 1887 she joined Beerbohm Tree's company; 7 June 1889 created the part of Nora in Ibsen's 'Doll's House,' the first presentation of Ibsen in English. She afterward starred in India and Australia, and in 1895 came to the United States, acting with Richard Mansfield and for herself. June 1897 she played Cleopatra (Shakespeare's) at the Olympic Theatre, London.

Acic'ulite, a mineral better known as needle-ore (q.v.).

Acidaspis («spine-shield»), a small trilobite widely distributed through Silurian and Devonian rocks, whose striking characteristic is the thick setting of the dorsal shield with such numerous and formidable spines that it must have been almost impossible for even much larger enemies to prey on it. The head-shield is entirely different from that of other trilobites, the trilobation being obscured by extra furrows and longitudinal false furrows. The thorax has 9 or 10 segments, each with long lateral spines and two shorter median ones; the small tail-shield in nearly all species also has them; in some a row of slender ones on the sides of the head-shield, and a long one projecting from each posterior angle; and from the middle posterior edge two long ones, straight or curved, often project upward and backward. A few species have the eyes placed, like some crabs and lobsters, on the ends of long, slender stalks, commanding a view in all directions.

Ac'idim'etry. See CHEMICAL ANALYSIS.

Acids. In popular usage, acids are substances of a corrosive nature, with a sour taste when diluted sufficiently to lose their corrosive action on the tongue, capable of turning certain blue vegetable coloring matters, such as litmus, to a red, and forming neutral compounds with alkalies. In modern chemistry an acid is usually regarded as a salt of hydrogen in which one or more of the hydrogen atoms are replaceable by metallic atoms or by organic radicals. An acid containing one such atom of replaceable hydrogen is called monobasic; if it has two such atoms of hydrogen it is called dibasic or bibasic; if three, tribasic; and so on. Hydrochloric acid, HCl, is a familiar example of a monobasic acid; it has only one atom of hydrogen that can be replaced by potassium (for example), with the formation of the single compound KCl. Sulphuric acid, H_2SO_4, is a familiar dibasic acid; with potassium it forms the two compounds $HKSO_4$ (hydrogen potassium sulphate), and K_2SO_4 (normal or basic potassium sulphate). Phosphoric acid, H_3PO_4, is a tribasic acid in which one, two, or all three of the hydrogen atoms may be replaced by metals or radicals. In a polybasic acid the hydrogen atoms need not necessarily all be displaced by the same element or radicals; thus microcosmic salt is a phosphate of hydrogen, sodium, and ammonium, with the formula $HNa(NH_4)PO_4 + 4H_2O$.

When an acid contains oxygen it is commonly named for the substance that is present with the oxygen and hydrogen in the acid. For example, nitric acid is named for nitrogen, and phosphoric acid for phosphorus. It often happens that the same element forms more than one acid with oxygen and hydrogen. In these cases it is usual to give the termination *-ic* to the one which contains the larger amount of oxygen, and the termination *-ous* to the one containing the lesser amount of oxygen. For example, H_2SO_4 is called sulphur*ic* acid, while H_2SO_3 is called sulphur*ous* acid. The salts formed by acids ending in *-ic* have the ending *-ate*, such as the acid sulphate of potassium, produced by substituting the metal potassium for one of the hydrogen atoms of sulphuric acid, while those formed by acids ending in *-ous* have the ending *-ite*. A vast number of organic acids are known, of which acetic acid is a familiar illustration.

Acknowledgment, the act of one who has executed a deed, in going before some competent officer or court and declaring it to be his act and deed. The function of an acknowledgment is twofold: to authorize the deed to be given in evidence without further proof of its execution, and to entitle it to be recorded. The same end may be attained by a subscribing witness going before the officer or court, and making oath to the fact of execution, which is certified in the same manner, but in some States this is permitted only in case of the death, absence, or refusal of the grantor. The certificate should be in substantially the following form:

——— —, 19—.

I, ——— ———, hereby certify that ——— ———, whose name is signed to the foregoing conveyance, and who is known to me, acknowledged before me on this day that being informed of the contents of the conveyance, he executed the same voluntarily on the day the same bears date.
Given under my hand this —— day of ——, 19—.

In many of the States it is necessary that a married woman be examined separately and apart from her husband touching her voluntary execution of the deed, and the fact of such examination must be included in the certificate.

Acland, Lady Christian Henrietta Caroline Fox, commonly called «Lady Harriet»; daughter of the first Earl of Ilchester: b. 3 Jan. 1750; d. 21 July 1815. She married Maj. John Dyke Acland, September 1770, accompanied him to America, and shared Burgoyne's campaign of 1777 with him. He being wounded and carried prisoner into the American lines in the second battle of Saratoga, 7 October, she left the British camp by night in a small rowboat and in a driving storm to rejoin him, with her chaplain and maid; was cordially received by Gates and nursed her husband back to health. Acland reciprocated the kindness when on parole in New York, by helping to relieve the sufferings of American prisoners. He died of a paralytic stroke 2 Dec. 1778; the gratifying story that he was killed in a duel for defending American courage against aspersion being pure invention. Equally untrue is it that she went insane and afterward married Chaplain Brudenell; she died Acland's widow. She was a graceful and elegant woman and is remembered for her charities.

Acland, Sir Henry Wentworth Dyke, English sanitarian: b. 1815; d. 16 Oct. 1900. He was long an expert on cholera and the various forms of plague. He was professor of medicine at Oxford (1858–94), besides serving on various sanitary bodies. He was one of the founders of the Oxford University Museum, and with Ruskin published an account of its objects (1859). He accompanied the Prince of Wales to America in 1860. He was author of 'Memoirs of the Cholera,' etc.

Aclin'ic Line, an imaginary line on the surface of the earth, at every point of which the magnetic dip is zero. It is irregular in shape, and its shape and position vary somewhat from year to year; but, roughly speaking, it lies close to the equator. See MAGNETISM, TERRESTRIAL.

Ac'mite, a mineral, in Dana's pyroxene group, crystallizing in the monoclinic system, and having essentially the composition $Na_2O.Fe_2O_3.4SiO_2$. Hardness 6 to 6.5; sp. gr. 3.5; lustre vitreous, inclining to resinous; usual color dark blackish-green or reddish-brown. Occurs in slender lustrous prisms in the elæolite-syenites of Norway, Greenland and Arkansas.

Acne, a disease of the sebaceous glands of the skin and of the hair follicles about them, characterized by an infection, an inflammation, and a breaking down of the tissue about the gland. Three main varieties are described, simple acne, deep or indurated acne, and acne rosacea, which is a complex affair.

Acne simplex.— In this form the affection is superficial, is found usually about the time of puberty, and is more often found in young women. It is a result of the great activities of the skin at this period of development, and is normal if not excessively developed. The «blackhead» or comedo is the first stage. This consists of the swollen sebaceous gland, slightly blackened at its outlet. This swelling continues, and a pustule forms, by reason of infection by one of the many pus-producing bacteria lying in and upon the skin. This results in an inflamed pimple, which may burst and discharge its contents, leaving a scar. In a badly inflamed area or pimply skin all stages of this development are usually present.

Acne indurata is a more deep-seated form. Here the gland lies deep in the skin, and, as it inflames, gives rise to the feeling of shot beneath the skin. These deep glands rarely rupture through the skin unless irritated by squeezing, in which instance they frequently form small boil-like pimples.

Acne rosacea is a combination of a disease of the skin, rosacea, plus an acne. This is the type of diseased nose so commonly termed a «rum-blossom.»

Acoma, ä-kō'ma, New Mexico (the old Spanish Acuña or Acuco), in Valencia co., 60 m. S.W. of Albuquerque and 15 m. S.W. of Lagun. It is an Indian pueblo of 492 people (566 in 1890), famed especially for its original site, the «Enchanted Mesa»: a rock table 430 feet high, accessible now only by scaling, and of old (traditionally) by spiral stairs cut in the stone, in a deep cleft of the upper portion and along a huge detached fragment leaning against it from the bottom, itself reached by a tall tree or a ladder, furnishing a secure fortress against enemies. The Indian tradition is that a long storm washed the loose earth away from the foot of the lower rock while all the tribe except

two women were away in the fields, and it fell over into the plain, leaving the upper portion inaccessible; the women perished, but the remainder of the tribe built a new place on the present site, which is the same as when the Spaniards found it. The essence of the tradition is verified by the finding of an old trail, and of shards, etc., in the talus high around the base. Acoma was visited in 1540 by Alvarado, of Coronado's command, and in 1582 by Espejo, who estimated the population at about 5,000. The Indians under Zutucapan stubbornly resisted the Spaniards, and in 1599 defeated a band of them from Oñate's force; later in the same year Zaldivar captured Acoma and slew five sixths of the inhabitants. A Spanish mission was afterward set up for the small remnant. (H. H. Bancroft's ‹Arizona and New Mexico,› 1880; F. W. Hodge, ‹The Enchanted Mesa,› ‹National Geographic Magazine,› vol. 8.)

Aconcagua, Chile, ä-kōn-kä'gwa (Sp.-Am. pron. kä'wä). (1) An extinct volcano in the S. Andes, on Chilean territory and dividing it from Argentina; one of the highest summits in the western hemisphere, estimated at about 23,000 or sometimes nearly 24,000 feet. (2) A river about 200 miles long, rising on the southern slope of the above mountain, and emptying into the Pacific 12 miles north of Valparaiso. (3) A central province of Chile, bounded N. by Coquimbo, S. by Santiago, E. by Argentina, S.W. by Valparaiso. For route of Trans-Andine Railway, via Uspallata pass in this province, see SOUTH AMERICA. The valleys are very fertile, vineyards and orchards are plentiful, and in summer numerous flocks are pastured on the mountain slopes; figs, nectarines, peaches, etc., are sent to Santiago and Valparaiso. Copper, silver, and gold are found. Area, 6,226 square miles. Pop. about 135,000. Capital, San Felipe.

Aconite (*Aconitum*), a genus of hardy herbaceous plants, of the natural order *Ranunculaceæ*, long known for their poisonous properties. Many of them are of great beauty, and several are cultivated, especially the common wolf's-bane or monk's-hood (*A. napellus*), so called from the form of its flowers, characteristic of the genus, which are shaped like a helmet or hood. The United States has also several species growing wild. The wild monk's-hood (*A. uncinatum*) is common in rich shady soils along the margins of streams as far west as Wisconsin, its blue flowers being one of the marked features of the summer's bloom. Trailing wolf's-bane (*A. reclinatum*), a white-flowered variety, grows in the southern Alleghanies. The winter aconite (*Eranthis*), with yellow flowers, is common throughout the Rocky Mountain regions extending to the Pacific coast. It is perhaps more closely related to the hellebores. These flowers hang clustered round an upright stalk and make the aconite a very imposing plant. Some powerful medicines are prepared from the leaves and roots of monk's-hood. Applied externally they produce numbness of sensory nerves, and are used to relieve pain in certain forms of neuralgia, and in acute and chronic rheumatism. Given internally they diminish the force and frequency of the heart's action, render breathing slower, and are employed in acute fevers and inflammations. A poisonous dose causes cessation of breathing and of the heart's action. All the plants of this genus are poisonous; common monk's-hood is very virulent; but the most deadly seems to be the *A. ferox*, the *bish*, or *bikh*, of Nepal.

Aconitic Acid, (also called equisetic or citridic acid), a tribasic acid having the formula $C_3H_3(COOH)_3$, the calcium salt of which occurs in several plants of the genus *Aconitum*, and in the common *Equisetum*, or horsetail. The acid itself is most easily prepared by the dry distillation of citric acid.

Aconitine, a powerful vegetable alkaloid found in the tuberous root of *Aconitum napellus* and other species of *Aconitum*. In its chemical structure it is an acetyl-benzoyl-aconine, $C_{21}H_{27}(OCH_3)_4NO_5.\left\{\begin{matrix}CO.CH_3\\COC_6H_5\end{matrix}\right.$, or, expressed in simple form, $C_{34}H_{47}NO_{11}$ (Freund and Beck). It is one of the most deadly poisons and has been known for hundreds of years. Its action as a medicine was first carefully studied by Stoerck in 1762. When locally applied it produces the constitutional symptoms. Its local use in the form of an ointment is of service in neuralgias. Internally its main action is on the heart muscle and on the blood-vessels. It slows the heart and dilates the blood-vessels, causing a marked decrease of blood pressure. It is because of this action that it is so widely used in the acute stages of many affections that are accompanied by a rapid heart and a tense, bounding pulse. Aconite has been called the «vegetable lancet» since it dilates the blood-vessels so, bleeding one into one's own veins, as it were. In poisonous doses it causes nausea, vomiting, cold, clammy skin, very slow weak pulse and breathing, and finally paralysis of the heart and respiration, and death. Death has taken place in from one to five hours from the root. Doses above 3 milligrams (1-20 gr.) a day are dangerous; 1-200 gr. is a safe initial dose. Treatment is symptomatic, special attention being paid to the respiration by artificial means, and heart stimulants,— strychnine, etc.

Acontius, in a Greek legend retold by Ovid in his ‹Heroides,› a youth of the island of Cea, who went to Delos to see the sacred rites performed by a crowd of virgins in the temple of Diana, and fell in love with Cydippe, a beautiful virgin. Not daring to ask her in marriage on account of the meanness of his birth, he presented her with an apple on which were inscribed these words: «I swear by Diana, Acontius shall be my husband.» Cydippe read the words, and, feeling herself compelled by the oath she had inadvertently taken, married Acontius. William Morris has used the story in the ‹Earthly Paradise.›

Acorn-shell, a barnacle of the family Balanidæ. See BARNACLE.

Acorus. See FLAG, SWEET.

Acosta, Gabriel, ä-kōs-ta, Portuguese philosopher: b. Oporto 1591; d. April 1640. Of a converted Jewish family, educated a Roman Catholic, his studies led him back to Judaism, and he fled with his mother and brothers to Amsterdam. He again developed heretical opinions, was taken to task by the synagogue, and excommunicated; his writings were confis-

cated and himself fined; and years of persecution by the Jewish authorities and his family drove him to suicide. Gutzkow made him the hero of his novel 'Die Sadducäer von Amsterdam' (1834), and of his tragedy 'Uriel Acosta' (1846). The work which caused Acosta's excommunication was 'Examen Traditionum Pharisæicarum Collatarum cum Lege Scripta' (1623, in Latin).

Acosta, Joaquin, ä-kōs'ta, hooä-kēn', South American soldier and geographer: b. Guachias, Colombia, 29 Dec. 1799; d. there 1852. He was an officer of engineers in the Colombian army, member of the New Grenada Convention 1831, later representative in its Congress. In 1834 he explored the Socorro valley to the Magdalena with the botanist Cespedes, and in 1841 traveled from Antioquia to Aserma to study the various Indian tribes. For a time he was minister from New Grenada to Ecuador; was *chargé d'affaires* at Washington 20 July to 8 Nov. 1842; and later secretary of state in New Grenada. He published at Paris in 1848 a history of the discovery and settlement of New Grenada, with a valuable map of his own drawing, the first made since the independence of Colombia; and in 1849, at Paris, a 'Miscellany of New-Grenadan Sciences, Literature, Arts, and Industries,' with portraits and map.

Acosta, José, ä-kōs'ta, hō-sā', Jesuit and historian: b. Spain, c. 1540; d. rector of Salamanca in 1600. In 1571 he went to Peru, where he spent 15 years, becoming provincial of his order. After two years in Mexico and the West Indies he returned to Spain laden with manuscripts and information, and became a royal favorite. His theological works evinced great learning, but it is by his 'Natural and Moral History of the Indies' that he is best known. The complete work was published at Seville in 1590 and proved the most popular and most satisfactory account of the New World up to that time. An English translation appeared at London in 1604, a reprint of which was issued by the Hakluyt Society in 1880.

Acouchi, or **Acouchy.** See AGUTI.

Acoumeter («hearing-measurer»), an instrument to determine the acuteness of hearing. It is a small steel bar of uniform pitch, to be struck with a hammer or falling weight with gradations of force.

Acoustics (from ἀκούειν, to hear) is the science of the production, propagation, and audition of sound. The term sound is sometimes by definition restricted to the sensation involved in hearing, but is never consistently so used. Both by derivation and by common and best usage it should be applied to those aërial or other vibrations which, were they to reach the ear, would produce audition. The term being thus used, sound consists of waves of longitudinal vibration, that is to say of waves of to and fro motion perpendicular to the wave front. Such motion, propagated through an elastic medium with a finite velocity, results in alternate rarefaction and condensation.

A moment's consideration of any source of sound will show it to be of such a nature as to give either a single impulsive blow or repeated blows, usually systematically repeated, to the surrounding medium. In the great majority of cases, and those the more interesting both theoretically and practically, the source of sound consists of an elastic body distorted from its normal shape, and, released, vibrating more or less symmetrically about this normal shape or position. It results from this vibratory motion that a series of impulses is given to the surrounding medium which are periodic, nearly similar in character, and nearly equally timed. These impulses, propagated through the surrounding medium all with the same velocity, follow each other in the form of a train of waves. The distance from a point in one impulse to the corresponding point in the next impulse is called the wave length of the sound. The frequency of these waves as they strike the ear determines the pitch of the sound; the character of the wave in respect to form determines the quality of the sound; while both of these together with the amplitude of vibration and the density of the medium determine the loudness or strength of the sensation.

In respect to pitch sounds audible to the human ear range in frequency from about 24 vibrations per second to 40,000 vibrations. Sounds very much higher in pitch are audible to some animals, the cat for example, while for some animals it is probable that the upper limit is not so high, although in regard to the latter point no reliable data have been secured, the interest of the biologists apparently being to extend the range. In regard to the lower limit in other auditors than man no reliable experiments have been made, and if attempted would be extremely difficult because of the difficulty of distinguishing the reactions due to the mechanical disturbance from the reaction due to true audition,— a difficulty which indeed affects all such experiments, but which is enhanced in the case of the lower limit.

The quality of a sound is determined by the wave form. A pure musical tone is due to simple harmonic motion, a type of periodic motion best described as the projection on a diameter of uniform circular motion, and most familiarly illustrated by the motion of the pendulum of a clock. Perfectly pure tones are rare, the nearest approach being that of a tuning fork reenforced by a resonator. Most musical sounds are far from being pure tones. They may, however, be regarded as a complex of a number of pure tones, each pure tone being then called a partial tone. Of these partial tones the lowest, which is generally though not always predominant, is called the first partial, and the other partial tones in order of their pitch are called the second, third, etc., partials. In many of the more interesting cases such as the tones of the organ pipe, or of a bowed, struck or plucked string, the upper partials are harmonics of the fundamental. The pitch and the relative intensities of the partial tones determine what is called the quality of the sound, the pitch of the whole being usually rated as that of the lowest partial. When a sound is incapable of analysis into pure tones it is called a noise. In many, indeed it is safe to say that in most sounds that are classed as noise there is some trace of a predominant note, and of a definite musical pitch which a trained ear can detect.

The loudness of a sound is capable of being variously defined. If by the loudness of a sound is meant physical energy and if the sound is a pure tone then its loudness depends on the amplitude of vibration and the pitch, being pro-

portional to the square of each, and on the density of the medium, to which it is directly proportional. The loudness of a sound is ordinarily defined, however, by the intensity of the sensation which it is capable of producing. Thus defined loudness is a function not merely of the amplitude of vibration and the density of the medium, but of the pitch and the quality as well, and moreover it is a complicated function of each. It is an interesting fact that in man there is a definite sense of loudness which renders it possible to compare, in respect to the intensity of the sensations which they produce, sounds differing in pitch by the whole of the musical scale. Moreover, this sense of loudness is apparently physiological and not dependent on familiarity with the "balance" of any musical instrument, and is to a high degree of accuracy the same for different persons, independent of age, sex, or musical training.

Production of Sound.— The best example of the single impulse as a source of sound is an explosion in unconfined and therefore non-resonant space. The result is an approximately single wave. When, however, the explosion occurs in a resonant cavity the result is a note of definite pitch determined by the cavity. Or a single explosion and impulsive wave may result in a train of waves and therefore a sound of definite pitch, by being reflected from uniformly spaced surfaces, such for example as the pickets of a fence. The next simplest source of sound is a siren, long a laboratory instrument, more recently made familiar by use in fog signals and steam whistles. The siren consists of two circular discs, the one fixed, the other pivoted to revolve nearly in contact with it. Both discs are pierced by a circle or by circles of holes through which steam or compressed air escapes as the holes in the two discs come opposite each other.

A straight bar of metal or wood may vibrate either transversely or longitudinally. If distorted transversely it vibrates to and fro through its normal straight form. The simplest form of this transverse vibration is that in which the bar at points one quarter the total length from either end remains at rest. These points of rest are called nodes and the intermediate part of free vibration is called an antinode. When vibrating in this manner the bar emits its fundamental note, the lowest note of which it is capable if entirely free. The next simple mode of vibration is that in which there are three nodes, or points of rest, at points one sixth the total length from either end and in the middle. In this case the bar emits a note having twice the frequency of the fundamental and in pitch an octave above it. Continuing in this way a series of simple types of motion may be determined. The notes thus produced have twice, three times, four times, etc., the vibration frequency of the fundamental. Any transverse free vibration of the bar is a combination of these forms, and the sound which it emits is a combination of these notes. In this manner the quality of the sound is determined. If the bar is clamped at one end the lowest note which it emits is an octave lower than the lowest when entirely free; and the higher tones, instead of being two, three, etc., multiples of the fundamental, skip every other one, being three, five, seven, etc., multiples of the fundamental. Touching the bar at any point tends to produce a node at that point and to strengthen the corresponding partial tone, and to diminish the partial tones having antinodes at that point. The exact converse is true in regard to striking the rod. Finally, the frequency of the several notes is proportional inversely to the length, and to the square root of the density, and directly to the square root of the rigidity, other dimensions being the same in each case.

When the rod is rubbed or stroked so as to vibrate longitudinally, either free or clamped at one end, its fundamental and overtones form the same systems as before, but all are of a different pitch, determined now by the length, density and modulus of elasticity. Thus the longitudinal vibrations of the free rod have as vibration frequencies of its overtones, all integral multiples of the fundamental. If the same rod is rigidly clamped at one end, its fundamental is an octave lower than the fundamental of the free rod, and the even integral overtones are absent.

A stretched string or wire, so small in diameter in comparison with its length that its rigidity is insignificant in comparison with its tension, vibrates for its fundamental over its whole length with nodes at each end. The first overtone is an octave above this in pitch, the wire vibrating with a node at the centre. The second overtone (third partial) is three times the fundamental in pitch frequency, the wire vibrating with nodes a third of the whole length of the wire from either end. The third overtone (fourth partial) is four times the fundamental in pitch frequency, with nodes at the quarter and middle points. A string set in vibration by any ordinary method vibrates in a more or less complex manner, emitting a sound containing the fundamental and overtones. The overtones present and their relative intensities are determined by whether the string is plucked, struck or bowed, and also by the point of application. The fundamental note emitted by a string is of a vibration frequency equal to the square root of the tension divided by the mass per centimeter of length, divided by twice the length.

If the vibrating elastic solid is in the form of a plate the system of overtones bears a complicated relationship to the fundamental, no longer being integer multiples in vibration frequency. The manner in which the plate vibrates may be shown by sprinkling sand on the plate, the latter being horizontal. When the plate vibrates the sand dances away from the parts of the plate in motion and settles in ridges along the nodes. When the plate is square and emitting its lowest tone the nodal lines traced by the sand form a cross reaching from the centres of the sides. By bowing the plate at different points the plate may be made to vibrate in very complicated forms. The sand figures thus traced often making attractive designs. The production of these various patterns is much guided by touching the plate at various points on the edge with the fingers, thus determining the ends of nodal lines. This experiment was first performed by Chladni, and the sand figures are called after their inventor Chladni's figures. Similar experiments can be carried out on stretched membranes, and one may investigate in this way the vibration of drum heads. The result of such an experiment shows that the quality of sound from a

drum depends on the point at which it is struck, and that the upper partials are inharmonics of the fundamental.

Next to the stretched string the most interesting case of a vibrating body is that of a column of air. To a first approximation the problem of the vibration of an air column is as simple as that of a stretched string, but in its practical forms and more accurate solution it is by no means so simple. The vibration of a column of air, according to the theory advanced by Bernoulli, is identical with the longitudinal vibration of a straight bar of metal. If the column of air is in a tube open at both ends, the simplest form of vibration and that in which it emits the lowest possible note is such that the air moves to and fro at both ends having a node at the middle. The first overtone, having a vibration frequency twice that of the fundamental, is produced by the column of air vibrating freely at both ends, vibrating freely at the middle, and having nodes at points one quarter of the total length of the pipe from either end. The second overtone has three times, the third overtone four times, etc., the vibration frequency of the fundamental. If the column of air is closed at one end the lowest tone which it can emit is an octave below the lowest tone emitted by the same pipe open at both ends. The overtones in this case are three, five, seven, etc., times the fundamental in frequency. The analogy of this with the bar of metal is obvious. It might be added that according to Bernoulli's theory the note emitted by the column of air is such that the sound could travel from the open end to the first node during one quarter of a vibration. This, only approximately true in the case of the column of air, is very strictly true in the case of the metal rod. It follows from this that the pitch of the note emitted by a column of air can be varied either by varying the length of the column, the pitch being inversely proportional to the length, or by so exciting the air that it vibrates according to the higher forms with nodes nearer the ends. The application of this to musical instruments is very simple. Take, for example, organ pipes of what are called flue stops as distinguished from reed stops. All such organ pipes are, obviously, open at the end at which they are blown. According as they are open or closed at the other end they are called open or closed pipes. Open pipes have nodes at their middle when sounding the fundamental note, while the closed pipes have their nodes at the closed end. A closed pipe is therefore an octave lower in pitch than an open pipe of the same length, accurately according to the theory of Bernoulli, but as a matter of fact only approximately so. In a pipe organ the variation in pitch is accomplished not merely by using open and closed pipes, but principally by using pipes of different lengths. The pipes not uncommonly vary in length from thirty-two feet to half an inch. In the military trumpet we have an exceedingly simple instrument whose whole available scale consists in the overtones, the particular note being determined by lip tension and wind pressure. In the slide trombone the scale is produced not merely as in the trumpet, but by varying the length by means of the slide. In the cornet the variation in length is accomplished by means of keys turning valves which throw into the length of the pipe or cut out from it short auxiliary convolutions. In the French horn the scale is played not merely by the means adopted in the cornet, but by means of the hand thrust into the bell or flared end, thus partially closing it and so lowering the pitch. In the flute, clarionet, and wood wind-instruments generally the variation in pitch is accomplished by opening and closing ports on the side of the tube.

A little more might be said in regard to stringed instruments. The strings are, in general, so narrow that when vibrating they cut through the air, communicating, practically, no motion to the air and therefore emitting, practically, no sound directly. The sound which we hear therefore comes not from the string, but from the sounding boards with which they are always placed in contact. It is thus because the sound which we hear comes from the body of the violin and scarcely at all from the strings directly that its quality depends so much more on the instrument than on the strings with which it is stretched.

Propagation of Sound.— When a sound is produced in free air at a distance from all obstacles it spreads in spherical waves, diminishing as it spreads over greater and greater surfaces, the intensity of the sound diminishing as the wave increases. The area of a sphere being proportional to the square of the radius we have the so-called law of the inverse square of the distance. The velocity of propagation of a sound through a medium is independent of the pitch of the sound or of its loudness and depends only on the nature of the medium — its elasticity and its density. In any medium the velocity of the sound is proportional directly to the square root of the elasticity and inversely to the square root of the density of the medium. Since the waves follow each other with so great rapidity that the air does not have time to cool during compression, the elasticity here referred to is that of adiabatic compression. A table is here given of the velocity of sound in various media.

Carbonic acid gas	866
Air	1,092
Hydrogen	4,190
Water	4,730
Pine wood	10,900
Copper	12,200
Iron	15,700

In this table the velocities given are in feet per second and at 0° C. A variation in temperature produces a variation in the velocity, particularly in the case of gases. A rise in temperature results in an increase of velocity, the increase being about .18 per cent for every degree Centigrade for all gases. This amounts to a little less than two feet per second in the case of air.

When the source of sound is coming toward the observer, the observer being stationary, the sound as heard is of a higher pitch than if the source were stationary, for the number of waves reaching the observer per second is increased in the ratio of the velocity of sound plus the velocity of the source to the velocity of sound. Similarly when the source is receding from the observer the sound received is of lower pitch. The change is strikingly observed as a bicycle bell or a clanging street car gong passes close by an observer. In

this case the fall in pitch is abrupt and marked. Similar phenomena are produced as the observer approaches or recedes from a stationary source. This is called Doppler's principle.

When the sound instead of being produced in uniform and stationary air is produced in air moving with various velocities the phenomena are much complicated. These phenomena were first studied with care in connection with fog signals by Henry, Tyndall, and Stokes. It was an old observation that fog signals plainly audible at a very great distance could often not be heard at a little less distance, still nearer were audible again, still nearer inaudible,— that these regions of silence and audibility varied, not merely on different days, but rapidly in the most mysterious and disconcerting manner, so much so as to receive the name of "sound ghosts." The explanation, for a long time sought in vain, was ultimately given in a suggestion by Stokes that they were due to a variability in the velocity of the wind in different strata of the atmosphere. The result of such an irregularity would be that the spreading sound waves instead of remaining spherical would be distorted very considerably. For example, the waves would be tipped back if the wind were greater at the higher altitude and against the sound. In such case the sound would rise from the water and there would be a region close to the surface over which the fog signal would be inaudible. If, on the other hand, the wind retarded the sound less above than below, or if the wind above favored the sound the wave would be tipped forward and the sound would descend upon the sea and there would be a resulting area of audibility. As the wind at different altitudes varies greatly and changes abruptly we have an entirely adequate explanation of the phenomena.

If the medium through which the sound is being propagated is not homogeneous another very interesting series of phenomena will occur. Whether the variation in homogeneity results from the variation in composition or a variation in temperature, the effect is the same. A change in either temperature or composition results in general in a change in the velocity of the sound. Whenever sound passes from one medium to another or from one region to another in which the velocity is different the direction of the sound is changed. It is said to be refracted. The law of refraction is a very simple one,— that the ratio of the sines of the angles made by the direction of propagation of the sound in the two media with a normal to the surface separating the media is equal to the ratio of the velocities in the two media. The sound is thus always bent toward the normal in passing from a medium in which the velocity is greater to a medium in which it is less. According to this principle the so-called acoustical lenses have been made. This may be done by filling a large but thin walled spherical balloon with some heavy gas. Such a lens properly placed will focus the sound of the ticking of a watch so that it can be heard at a distance considerably greater than that at which it can ordinarily be heard. When the lens is thus made with heavy gas it is a converging lens; when made with light gas it is a diverging lens. A curious but unintentional example of the latter occurred in the House of Parliament when a shaft of warm air, rising through the large ventilator in the middle of the floor, so diverted the sound that a speaker on one side could not be heard clearly by a member immediately opposite him.

Whenever a sound traveling through one medium comes to another medium in which its velocity is different a certain portion is reflected, the amount reflected depending upon the change in velocity of the sound and upon the angle at which it strikes the surface of separation. This furnishes the explanation of the so-called aërial echoes observed by Tyndall, and a partial explanation of the rolling of thunder.

When the reflecting surface is a solid wall a very large per cent of the sound is reflected, how much, depends, of course, on the nature of the wall. Under these circumstances there are produced a large number of important phenomena which are most strikingly interesting in connection with architectural acoustics. Under special but usually accidental conditions very peculiar phenomena arise as is illustrated in the case of whispering galleries. Whispering galleries are of one or the other of two general types usually illustrated, following the lead of Herschel, by the dome in Saint Paul's Cathedral, London, and by a much less familiar building, the cathedral in Girgenti. In Saint Paul's Cathedral if a person takes a position at one side of the dome and very close to the wall he can whisper with great ease and distinctness to a person at the opposite side of the dome. This is not the case of focusing sound in the ordinary sense. The sound starting from one point is carried by the curved surface along great circles on the interior of the almost spherical dome. The sounds traveling by all these paths meet again at the opposite end of the diameter. As distinguished from this the whispering gallery in the cathedral at Girgenti is produced by a single, isolated, but focused reflection. A better and more familiar illustration of this was until recently to be found in the Hall of Statues in the capitol at Washington. It is a necessary condition for both types of whispering galleries that the wall surfaces should be smooth and free from great projections. The whispering gallery in the Capitol at Washington has recently been destroyed by replacing the formerly smooth spherical ceiling by a rather deeply coffered ceiling in plaster. The ideal whispering gallery, should one be planned, would be secured by constructing a room a considerable portion of whose wall surface would be part of an ellipsoid of revolution with foci at the points between which the whispering is to occur. Another interesting and somewhat related phenomenon is that of multiple reflections. An interesting example of this recently occurred in a private athletic court at Rhinebeck-on-the-Hudson. In this case the ceiling was a smooth dome so nearly flat that its centre of curvature was at a distance below the floor equal to the height of the room. Here the echo was repeated very many times and the sound was reflected three times between each repetition of the echo. Such special forms of walls not infrequently occur in auditoriums, often in a subtly concealed manner, and are the occasion of much annoyance. It might be added that it would not be a safe generalization to say that all curved surfaces are bad or that all disturbing surfaces are curved.

In the absence of specially disturbing surfaces the multiple reflection of the sound results in a general reverberation, which is from some points of view advantageous and from some harmful. The reverberation results in an increased loudness particularly of sustained tone. On the other hand by the prolongation of each sound it results in more or less confusion. When the room is to be used for musical purposes, the effect of this reverberation, unless it be carried to too great an extent, is to blend the tones and to give to the performer a sense of support from the auditorium. There is apparently a nice balance which for the best musical effects must be accurately attained in order to fully satisfy expert musical taste. The reverberation in the room as well as the general loudness and even the loudness at the several points can be calculated when the dimensions of the room and the absorbing power of its various surfaces are known.

Another feature of architectural acoustics is the phenomenon of interference. Taking first the simplest possible case when a sound from a distant source strikes normally on a plane wall, the reflected waves meeting the following on-coming waves produce by their superposition a system of stationary waves parallel to the reflecting surface. The result would be great nodal and antinodal surfaces parallel to the reflecting wall. An observer moving about in such a medium would hear the sound as very loud at the nodal surfaces. When the sound is produced in a confined space, such as a room, it is reflected from wall to wall many times and in many directions before it is ultimately absorbed. The result is an exceedingly complicated system of stationary waves. Under certain conditions the sound may be so intense at certain points of the room as to be unendurable, while at other points but a few feet distant it is so faint as to be scarcely audible. The distribution of such a system of stationary waves depends on the shape of the room, the material of the walls, and the position of the source of sound. It also depends on the pitch of the sounds.

When the conditions of the room are such that a system of stationary waves are so formed that a region of great intensity coincides with the source, the phenomenon of resonance occurs. That is to say the emission of that particular note will be increased in comparison with other notes of such pitch that their greatest nodal intensity in their own interference systems do not coincide with the source. This phenomenon is called resonance. Both interference and resonance result in the destruction of chordal balance.

Audition.— The ear is ordinarily divided, in anatomical work, into three parts, the outer, the middle and the inner ear. The drum of the ear separates the outer from the middle ear, the middle ear being an air cavity connected by the eustachian tube with the nasal cavity. The sound is conducted across the middle ear by a system of three bones which connect the drum with another membrane separating the middle ear from the inner ear. The inner ear is a somewhat complicated cavity in the solid bone of the skull. It consists essentially of three semicircular canals, and a much longer and larger snail-shell-like cavity called the cochlea. This inner ear is separated from the middle ear not merely by the membrane already referred to pressed against and vibrated by the bones, but also by another small membrane. Starting from between these two membranes a diaphragm runs the length of the cochlea. This diaphragm somewhat intricate in its complete structure, has as an essential part a system of numerous stretched fibres, varying in length and probably also in tension. When the sound is conducted from the outer ear to the inner ear by the three bones in the middle ear, the vibration is communicated to a liquid which fills the inner ear. This liquid in vibrating causes the small fibres of the diaphragm, called the fibres of Corti, to vibrate. As the fibres of Corti are of different lengths and of a different tension, different regions of the diaphragm respond to different notes. On this diaphragm terminate the auditory nerves which are stimulated by the vibration of the fibres, and communicate the corresponding sensation to the brain. The variation in pitch sensation is due to variation in the stimulated region of the diaphragm. When the sound is not a pure tone the various partial tones excite the corresponding parts of the diaphragm. When two notes are sounded, each with its system of overtones, there are regions of the diaphragm more or less excited simultaneously by the two systems. When the two partials which excite overlapping regions of the diaphragm are not of exactly the same pitch beats occur between them. These beats when slow are not wholly disagreeable, and having a tremulo effect in moderate use are not without musical value. When, however, the beats are more rapid, and this occurs when the overlapping partial tones differ more in pitch, the beats lose their distinct character as such and produce the effect known as discord. If the two partial tones differ still more in pitch the regions which they excite overlap less and less and the discord diminishes. Following out this line of argument Helmholtz was able to show that when the fundamentals having harmonic upper partials bear to each other simple ratios in their vibration frequency their discord is a minimum, deriving in this way a complete explanation of the musical scale as used in harmonic composition. The scale thus obtained is the true or natural scale. The intervals between the successive notes are not equal, but fall into two groups of so-called whole and half tone intervals. The whole tone intervals are not equal among themselves and are not twice the half tone intervals. Therefore, even after inserting sharps and flats to sub-divide the whole tone intervals the resulting chromatic scale is not one of equal interval. While this is the scale which would be employed by instruments without fixed key-boards, and by the human voice accurately trained, it cannot be employed in instruments with fixed key-boards if such instruments are to be used in different keys.

For this purpose Bach invented a scale called the equally tempered scale in which all the half tone intervals are made equal. On this scale no key is accurate, but no key is so inaccurate as to result in serious discord. The following table gives the vibration frequency of the eight notes of the middle octave on the natural and on the tempered scale:

	Natural Scale.	Tempered Scale.
C	258.7	258.7
D	291.0	290.3
E	323.4	325.9
F	344.9	345.3
G	388.0	387.6
A	431.1	435.0
B	485.0	488.2
C	517.3	517.3

As the invention of the musical scale long preceded its use in harmonic composition, and during the period preceding the 11th century was used only in melodic composition — that is for notes sounded in sequence — the simultaneity necessary for harmonic effect was obtained by the prolongation of one note into the other. This probably resulted from reverberation due to architectural conditions.

Wallace Clement Sabine,
Professor of Physics, Harvard University.

Acquaviva, Andrea Matteo, än'drā-a mät'-ā-ō äk'wa-vē'va, Duke of Atri and Prince of Teramo, in the kingdom of Naples: b. 1456; d. 1528. He seems to have been the first who conceived the idea of an 'Encyclopædia,' or 'Universal Dictionary of Arts and Sciences.' He published a useful work under that title in two folio volumes.

Acqui, äk'wē, N. Italy. (1) A district in the province of Alessandria, on the N. side of the Ligurian Apennines. Area, 445 sq. m. Productions, corn and fruit. Chestnut-trees furnish the peasantry with an article of common food, and silkworms are reared. (2) Its capital and episcopal city, on the Bormida, 18 m. S.S.W. of Alessandria, 37 m. N.W. of Genoa. It has commodious hot sulphur baths, and is celebrated for its great antiquity and for the remains of a Roman aqueduct. The hot sulphur baths were known to the Romans, who called the place *Aquæ Statiellæ.* There is an extensive trade in wine, silk, lace, and rope. Acqui has a cathedral, a royal college, and is a bishop's see. It was taken by the Spaniards in 1745; retaken by the Piedmontese; and afterward dismantled by the French. Pop. (1901) 13,786.

Acquisition is the act by which a person procures property in a thing; also the thing the property in which is secured. Original acquisition is that by which a man secures a property in a thing which is not at the time he acquires it, and in its then existing condition, the property of any other individual. It may result from occupancy, accession, or intellectual labor.

Acquittal, in law, the judicial setting free or releasing a person from a contract, debt, or other obligation; but the term is more commonly used in criminal law to signify the deliverance from a charge of an offense, either by a verdict of not guilty by a jury, or by simple operation of law, as in the case of an accessory where the principal is acquitted. In the United States acquittal may be the result of some technical defect in the proceedings or by the verdict in favor of the accused on the merits of the case. In the first case a second trial of the case may be instituted, but the second case is a bar to any further prosecution of the accused for the same offense. This is guaranteed by a Constitutional provision that "no person shall be twice put in jeopardy for the same offense."

Acræinæ, a sub-family of butterflies of the family *Nymphalidæ,* deriving its name from the leading genus *Acræa.* There are about 85 species, mostly African. They are of small or moderate size, and have semi-transparent wings, reddish-brown marked with black.

Acra'nia, a primary division of *Vertebrata,* represented by *Amphioxus* (q.v.) in which, as the name indicates, there is no skull, while the notochord extends to the anterior end of the snout, in advance of the central nervous system. There is no true brain, the region corresponding to the brain of the genuine vertebrates being very imperfectly differentiated. There are only two pairs of cerebral nerves, and the dorsal and ventral spinal nerves do not unite. There is also no trace of limbs. The pharynx is of comparatively immense size, perforated by very numerous gill-slits, and surrounded by an atrium. The liver is a hollow pouch of the intestine. There is no heart, and the blood is colorless. The numerous nephridia remain distinct and open into the atrium. There are no paired eyes, only a single median pigment-spot in the wall of the brain; there are no ears, though an olfactory pit is present. The reproduction glands are segmentally arranged, but have no ducts.

Acrasia (Gr. ἀκρασία, intemperance), a beautiful woman, the personification of all that is intemperate and immoderate, portrayed in Spenser's 'Færie Queene.' She lives in a "Bower of Bliss," on a floating island, in which there is everything to delight the senses. Her character was suggested by Circe, but probably more directly by the Alcina of Ariosto.

Acre, Syria (Biblical *Accho,* Greek *Ptolemais,* other forms *Acco, Akka, Acon, Accaron;* modern French St. Jean d'Acre), a port some miles north of Mt. Carmel, on the Bay of Acre, opposite Haifa on the opposite horn. The harbor is one of the best on the coast; even so, it is much choked with sand. Its interest is chiefly in its varied and picturesque past: as the chief landing place for invasion of Syria, it has perhaps suffered more from political revolutions and war ravages than any other place in history. Its name first occurs in a letter of King Burnaburiash of Babylon to Amenhotep IV. of Egypt, c. 1400 B.C. Sennacherib of Assyria captured it 701 B.C., and his son Esarhaddon about 675 gave it to the king of Tyre. After the break-up of Alexander's empire, Ptolemy Soter of Egypt took possession of it and renamed it Ptolemais; it afterward became part of the Seleucid empire of Syria; and later the Romans acquired it and made a colony of it. Under the early empire it was a city of great importance, and remnants of its grandeur in the shape of fine granite and marble pillars still exist. In 635 A.D. the Saracens under Khaled and Obeida captured it and Damascus. They were expelled from it in 1110 by the Crusaders, who made it their principal port and retained it till 1187, when it was recovered by Saladin. Four years later it was retaken by Richard Cœur de Lion and Philip II. of France, at the cost of 100,000 lives. They made it a bishopric and gave it to the order of St. John (Fr. St. Jean, from which it took its French title). These held it for just a century, despite continual assaults from the Saracens; and it

was a large, rich, and powerful city, filled with churches, convents, and hospitals. In 1291, when it had become the last Christian stronghold left in Syria, the Saracens retook it after a bloody siege which injured it greatly. From that time it sank rapidly. In 1517 it fell into the hands of the Turks under Selim I.; and at the beginning of the 18th century it was a vast scene of ruin, relieved only by a few cottages, a mosque, and the houses of French factors. Toward the end of that century the Turks, especially Djezzar, much strengthened and improved it, and it rose to some importance again. It is best known in modern times for its brave and successful defense in 1799, by means of a body of English soldiers and marines under command of Sir Sydney Smith, against Napoleon, who, after spending 61 days before it, was obliged to retreat. It continued to prosper and be the seat of a considerable trade till 1832, with consuls from all the great states, though crippled by the imposts, monopolies, and misgovernment with which the Turks blight every place that endures them. On the revolt of Mehemet Ali, the great Viceroy of Egypt, his son Ibrahim besieged it for 5 months and 21 days in the winter of 1831–2, and before he captured it, its public and private buildings were mostly destroyed. The Egyptians repaired and improved its fortifications; but on 3 Nov. 1840 a 3-hours bombardment by a combined English, Austrian, and Turkish fleet reduced it to a ruin. The Turks were again put in possession of it in 1841.

Acre, originally «field,» «pasture,» «hunting-ground»; but later a rough measure of size, somewhat similar in different countries, and supposed to represent what one man could plow in a day. The Italian term *giornate* (day's work) is significant on this point. In England reckoned as the amount a yoke of oxen could plow in a day, till the laws of the 13th century and later settled a definitive measure. There and in the United States this is termed the *statute acre,* old customary acres being still used in Scotland, Ireland, and Wales, as well as in several English counties, all different and some of them less than half the statute, while others are more than double. The statute acre is 43,560 square feet, or 4,840 square yards, or 160 square rods or perches (from the yard and the rod or pole with which it was measured); also divided into 4 roods, though this and perch are mere book-words in the United States at least, as is the square «chain» of 22 yards or 484 square yards, from the surveyor's chain used in measuring it. The following table gives various measures in relation to the English and American acre. The German empire having adopted the French metrical system, the German *morgen* are becoming of historical significance merely.

Acré River, ä'krā, South America (also called **Aquiry,** ä'kē-rē), a tributary of the Purus River. Its sources have not yet been precisely located, but are probably on the eastern Andean slopes near lat. 11° S. From the point at which it becomes navigable for small steamers its course is generally northeast to its confluence with the Purus; the latter flows nearly parallel to and north of the Madeira, emptying into the Amazon west of Manáos. Together these rivers give access to an exceedingly valuable rubber forest district, long in dispute between Bolivia, Peru, and Brazil. The name Acré is commonly applied to the entire region. Bolivia, claiming that her sovereignty had been recognized by Brazil in the treaty of 1867 and by subsequent acts, granted a conces-

sion for developing the rubber products to an Anglo-American syndicate in 1902; but she was not allowed to live up to this agreement, though she had troops and a military governor on the ground. The Brazilian inhabitants rose, imprisoned or drove out every Bolivian in the district, captured Port Acré 24 Jan. 1903, installed a new governor, and proclaimed their allegiance to Brazil. The latter country thereupon sent an ultimatum to Bolivia, and on 8 February the Bolivian government agreed to admit Brazilian occupation pending a settlement. The treaty between Bolivia and Brazil signed 17 Nov. 1903 provides for the relinquishment by the former country of all that part of the vast Acré region lying north of the Abunan, in lat. 10° 20′ S., and a line following water courses in a southwesterly direction from that point to lat. 11° S., or approximately to the sources of Acré River. Brazil agrees to pay "an indemnity of £2,000,000 sterling, which the Republic of Bolivia accepts with the intention of using the same mainly in the construction of railways or other works tending to improve the communications and develop commerce between the two countries" (Art. 3). Moreover, Brazil (in Art. 7) "binds herself to build on Brazilian territory, by herself or by a private company, a railway to extend from Santo Antonio on the Madeira River to Guajará-Mirim on the Mamoré, with a branch road running through Villa-Murtinho, or another point near it in the State of Matto Grosso, to Villa Bella at the confluence of the Beni and Mamoré," the object being to furnish an outlet to the Madeira and Amazon for Bolivian products (see SOUTH AMERICA); and in Art. 8 Brazil "declares that she will negotiate directly with the Republic of Peru the boundary dispute concerning the territory comprised between the source of the Javary (or Yavari: about lat. 7° S.) and parallel 11°, and will endeavor to reach a friendly solution of the litigation." Bolivia and Peru agreed by treaty of 21 Nov. 1901 to submit to arbitration all controversies pending between them; their long-standing boundary disputes were actually referred to the President of the Argentine Republic as arbitrator in 1904. There still remained to be determined the conflicting claims of Peru and Brazil to that portion of the great Amazon basin comprised between lat. 7° S. and lat. 11° S.; extending from the eastern cordillera of the Andes to the heart of the continent; watered not only by the Acré but by the Juruá and Purus rivers as well; a country imperial in size and of incalculable undeveloped resources, yet so situated that it is wholly dependent upon Brazil. An examination of the maps (see SOUTH AMERICA) will show that the lands in question are valueless unless Brazil keeps open the only outlets for their produce, the waterways through Brazilian territory to the Atlantic; that, therefore, Peru cannot reasonably hope to gain anything in this contention by force of arms if Brazil is unwilling to yield. Besides, a resort to arbitration was indicated as the proper course by the experience of Bolivia and Brazil. Nevertheless, when Brazil demanded the evacuation of points in the disputed territory occupied by Peru, as a condition precedent to arbitration, Peru refused compliance, saying that she, for her part, proposed arbitration "without demanding previous conditions which should be regarded as unnecessary by governments really wishing to reach a prompt, just, and pacific settlement of their differences" (May 1904). The delay proved fatal to Peruvian interests in this quarter. While diplomatic notes were being exchanged, Brazilian troops from Manáos defeated the small army of occupation maintained by Peru. Thus the Acré-Purus-Juruá region passed under Brazilian control.

Acres, Bob, an awkward young country booby of the gentleman class of England, who figures in Sheridan's comedy of 'The Rivals.'

Acrisius, in Greek mythology, king of Argos. He expelled his twin brother Prœtus (q.v.) from his inheritance and for a time ruled alone in Tiryns and Argos, but was later forced to surrender to his brother the former kingdom. He was the reputed founder of the Delphic amphictyomy. For the legend concerning the prediction of the oracle that he would die at the hands of his grandson, see PERSEUS.

Acrobat. See GYMNASTICS.

Acroceraunium, ak′rō-se-râ′nē-um, the N.W. promontory of Epirus, with mountains called Acroceraunia ("thunder-peaks"), which separated the Ionian and Adriatic Seas, and were noted for attracting storms, and hence dreaded by mariners. Its modern name is Chimara or Cape Glossa, or Cape Linguetta.

Acrocorinthus, in ancient times the acropolis or citadel of Corinth: a steep rock nearly 1,900 feet high, overhanging the city, and crowned with the remains of Venetian and Turkish fortifications, ruins of mosques and dwelling-houses, and also a barrack with a few soldiers. On its top stood of old a temple of Aphroditē.

Acrop′olis, the high part of any ancient Greek city; usually an eminence overlooking the city, and frequently its citadel. Notable among such citadels were the Acropoleis of Argos, of Messene, of Thebes, and of Corinth; but preeminently the Acropolis of Athens, to which the name is now chiefly applied. This was the original city (as indeed most of the acropoleis, dating from the times of barbaric insecurity), later the upper city as distinguished from the lower, and was built upon a separate spur or butte of Hymettus. The hill rises out of the plain, a mass of rock about 260 feet high, with precipitous sides save for a narrow access at the western end where there was a zigzag road for chariots. The summit of this rock forms an uneven plain 500 by 1,150 feet at the maximum breadth and length. Within this area were reared, chiefly in the days of Pericles, remarkable specimens of architectural art. The buildings were grouped around two principal temples, the Parthenon and the Erechtheum. Between these temples stood the statue of Athene Promachos («fighter in front»), by Phidias, the helmet and spear of which were the first objects visible from the sea. About these centre-pieces, covering the rocky height and extending down the steep sides, were lesser temples, statues, theatres, fanes, and odea (music halls). Among the famous buildings on the sides of the Acropolis were the Dionysiac theatre, the Odeum of Pericles, and the Odeum, built by Herodes Atticus in honor of his wife Regilla. The ravages of accident and war and Athenian marble-

merchants, and in case of the Parthenon (q.v.) its deliberate dismantling by Lord Elgin early in the 19th century, have largely destroyed and despoiled these classic works. Archæologists have secured many important remains of the Acropolis, which are preserved in the collections of various European capitals and in the new archæological museum at Athens.

Acros'tic, a poetical composition, disposed in such a manner that the initial letters of each line, taken in order, form a person's name or other complete word or words. This kind of poetical trifling was very popular with the French poets from the time of Francis I. until Louis XIV. Among other English writers, Sir John Davies, who lived in the 16th century, amused himself in this way. He produced 26 pieces called ‹ Hymns to Astrea,› each of them forming an acrostic upon the words Elisabetha Regina. The following is an example:

E ternal virgin, goddess true,
L et me presume to sing to you.
I ove, e'en great Jove, hath leisure
S ometimes to hear the vulgar crew,
A nd heed them oft with pleasure.

B lessed Astrea! I in part
E njoy the blessings you impart,
T he peace, the milk and honey,
H umanity and civil art,
A richer dow'r than money.

R ight glad am I that now I live,
E 'en in these days whereto you give
G reat happiness and glory;
I f after you I should be born,
N o doubt I should my birthday scorn,
A dmiring your sweet story.

In the Old Testament there are 12 psalms written according to this principle. Of these the 119th Psalm is the most remarkable; it consists of 22 stanzas, each of which commences with a Hebrew letter and is called by its name. Acrostic verse is no longer cultivated by serious poets, and has in fact been relegated mainly to country newspapers, except as a jest or social pastime. Edgar Allen Poe, however, wrote some striking acrostics, varying the form with great ingenuity. One example, beginning with the first letter of the first line, the second of the second, and so on, forms a lady's name.

Acroterion (« extremity »), in architecture, an ornament — statue, palmette, or leaf-decoration — placed on the apex of a pediment or one of its lower angles.

Act. *In the drama:* one of the parts into which a play is divided, to mark change of time or place, to give a respite to the actors and audience from the strain and physical fatigue of sitting intent on a long play, and to enable actors to change costumes and managers to change scenery. In Greek plays, where there was no scenery and no change of costume, there were no separate acts,— the episodes separated by the lyrical portions being not such either in design or effect,— and the action was continuous from beginning to end and the unities strictly observed. If the principal actors left the stage, the chorus took up the argument and contributed an integral part of the play; chiefly in the form of comment on the action, but often by supplying necessary information impossible to give in the regular speeches. When it was desired to develop the story further than the single play could conveniently do, another *drama*, — etymologically the same as *act*,— carried it on to another time or place, forming the common Greek trilogies, or groups of three, in which the same characters reappear. The Roman theatre first adopted the division into acts, suspending all stage business in the intervals. They made the regular number five, and Horace sets this down as a fixed rule of art. On the revival of letters it was almost universally used by dramatists; and that it rests on something more than caprice is shown by the fact that Shakespeare, who cared nothing for fixed rules of art and utterly disregarded the unities, never varies this division. For a great drama there is a real reason, though in light comedy it is almost universally dropped at present. The natural division is into three,— introduction, climax, and conclusion; and the central act still fulfills the same function. But for a great action this is apt to hurry matters too fast for a proper development either of character or interest; hence the first and the last act are doubled, the approach to the main point and the preparation for the catastrophe being both rendered more gradual. Some critics have laid down exact rules as to the part each act is to sustain in a play; but these cannot be justified and have never been regarded. It is obvious, however, that each act should form a certain unity, ending with a point of deep but suspended interest, yet should be an integral part of the whole. Molière began the three-act comedy; but even to an impatient generation this is too short for a play of power, and four is most preferred. See DRAMA.

In Law.— (1) Anything officially done by the court, as the phrases « Acts of Court,» « Acts of Sederunt,» etc. (2) In bankruptcy, an act the commission of which by a debtor renders him liable to be adjudged a bankrupt. (3) In civil law, a writing which states in a legal form that a thing has been said, done, or agreed. (4) In evidence, the act of one conspirator performed in pursuance of the common design may be given in evidence against his co-conspirators. (5) Acts done, distinguished into acts of God (q.v.), of the law, and of men.

In mental philosophy, an operation of the mind supposed to require the putting forth of energy, as distinguished from a state of mind in which the faculties remain passive. In this sense such expressions as the following are used: the act of thinking, the act of judging, the act of resolving, the act of reasoning or of reason; each of these being viewed as a single operation of the human mind.

In parliamentary language, an ellipsis for a law enacted by a congress, legislature, parliament, etc. A statute, law, or edict, consisting of a bill which has been successfully carried through both Houses of Congress or legislature, and received the approval of the executive. See specific titles *infra,* ACT OF GOD; ACT OF SETTLEMENT; ACT OF SUPREMACY; ACT OF TOLERATION; ACT OF UNIFORMITY.

In theology, the carrying out of an operation in a moment, as contradistinguished from the performance of a work requiring a considerable time for its accomplishment.

In universities, of old, the commencement or taking of degrees; now disused save as a form at Cambridge, England. The student « keeps the act » by reading a Latin thesis which he must defend against three opponents named by the proctors.

Acta Diurna («Daily Acts»); also called ACTA POPULI, «Acts of the People»; PUBLICA, «Public Acts»; URBANA, «Municipal Acts.» Written daily newspapers in ancient Rome, posted up in public to be read or copied, then taken down and filed in the public archives. The news was collected by reporters (*actuarii*) employed by the State, and consisted of much the same sort of matter as that contained in modern newspapers: a miscellany of everything that might interest the citizen, from the latest war news, abstracts of the best speeches in the Senate or Forum or the courts, the most important legal decisions or political events, probably even to interviews, down to the most trivial gossip of the town,— not only births, marriages, divorces, and deaths, murders, domestic infelicities, and accidents, but any unusual omens or prodigies, *lusus naturæ*, etc. Petronius in ‹Trimalchio's Feast› gives an admirable burlesque of it. The letters of Romans to out-of-town friends were regularly furnished with spicy news from the *Acta Diurna*, which seem to have taken the place of the older ‹Annales› or yearly chronicles, too slow for the active later republic and only reporting the more important occurrences, some time after 131 B.C. The usual statement is that Julius Cæsar introduced them; but it hardly seems probable that the Roman people, once used to even an imperfect form of news-gathering, dispensed with it altogether for three-quarters of a century and did not think of it again until it was invented for them. It is certain, however, that it was in use in Cæsar's time, for he ordered Antony's offer of a crown to him on the Lupercalia to be set down in the *Acta Diurna*. (Le Clerc, ‹Roman Newspapers,› in French, 1838, entertaining but not cautious in facts; Hübner, ‹Acta of the Roman Republic,› in Latin, Leipsic, 1860.)

Actæa, a genus of the natural order *Ranunculaceæ*, represented in the United States by the baneberries. *A. alba* or white cohosh, or baneberry, is found in rocky woods north from Georgia. *A. spicata*, red cohosh, or red baneberry, grows farther west and near to the north than the white baneberry.

Acta Eruditorum, the first literary journal of Germany. It was started in 1682 by Prof. Otto Mencke of Leipsic, and enjoyed a long existence and great popularity. It was owned by his family till 1754, after which it began to decline in value and in the number of its subscribers; and the irregularity of its appearance became at length so great that the last volume, for 1776, was published in 1782, exactly a century from the time when the journal was commenced. The whole consists of 117 quarto volumes, including the supplementary volumes and indices. In this journal Leibnitz first gave to the world his notions respecting the differential calculus.

Actæon, ak-tē'on, in Greek mythology, the son of Aristæus and Autonoë (a daughter of Cadmus), a great hunter. He was turned into a stag by Artemis (Diana) for looking at her when she was bathing (or, as some say, for boasting that he was superior to her in hunting), and was torn to pieces by his own dogs. This incident is exhibited in various ancient works of art.

Acta Sanctorum, or **Martyrum**, the collective title given to several old writings respecting saints and martyrs in the Greek and Roman Catholic Churches, but now applied especially to one extensive collection begun by the Jesuit Rosweyd, and continued by J. Bolland. The work was carried on (1661) by a society of learned Jesuits, who were styled Bollandists, until 1794, when its further progress was prevented through the invasion of Holland by the French. In recent times the undertaking has been resumed.

Actin'ia. See SEA-ANEMONE.

Actinia'ria (Gk. *aktis*, ray), the sea-anemones. See ANTHOZOA; SEA-ANEMONE.

Actin'ium. (1) A supposed metallic element, occurring in nature associated with zinc. Its existence was announced in 1881 by Dr. T. L. Phipson, who observed that certain salts of zinc gave a white precipitate of zinc sulphid which blackens upon exposure to light and returns again to its white state in the dark; the blackening effect not being observed when the substance is exposed to the light *under a sheet of glass*. Phipson attributed this action to the presence of a previously unrecognized element which he called *actinium* on account of the sensitiveness of its sulphid to light. The zinc sulphid with which he experimented appeared to yield about four per cent of actinium sulphid, and he suggested that "the presence of this new element in zinc will account, probably, for the discrepancies noticed in the equivalent of this metal as determined by various observers." The hydrate of actinium is described as a voluminous, white, gelatinous precipitate, with a slight tinge of salmon when seen in bulk. The anhydrous oxid is not volatile and has a pale fawn color. The sulphid is of a pale canary-yellow color, and when exposed to the direct rays of the sun, unshielded by glass, it becomes quite black in about 20 minutes. Dr. Phipson's account of the preparation of the salts of actinium is given in the ‹Journal of the Franklin Institute› for December 1881. The existence of the element is not now admitted by chemists. (2) A radioactive substance, presumably an element, discovered by A. Debierne in 1000. It gives off the same kinds of rays as radium, but the "emanation" that it emits dies away with great rapidity. Actinium, like radium and polonium, is prepared from pitchblende, and belongs to the iron group. See RADIOACTIVITY.

Actin'ograph, a name sometimes given to the actinometer (q.v.), especially when it is arranged so as to give an automatic record of the intensity of the light.

Actin'olite, a mineral in Dana's Amphibole group, having the composition $Ca(Mg,Fe)_3Si_4O_{12}$. It occurs in various forms, and includes the varieties nephrite, asbestus, smaragdite, urolite, cummingtonite, dannemorite, and grunerite. Actinolite is greenish in color, and occurs usually in the form of long slender crystals or in a fibrous and radiated state.

Actinom'eter, an instrument for measuring the intensity of the chemical action of the sun's rays. For use in photography for the judging of times of exposure, the essential part of the instrument is a strip of sensitive silver

paper, which is blackened by the sun's rays, the time required to darken the paper to a definite shade being taken as the index to the intensity of the light. Any other chemical action that light rays are capable of performing may be made the basis of an actinometer; but the indications of instruments in which the fundamental chemical changes are different will not necessarily agree with one another, because any given actinometer shows nothing but the intensity of the particular part of the spectrum which performs the chemical change upon which that instrument is based.

Actinomyco'sis, a disease due to a vegetable parasite, *Actinomyces bovis*, of the fungus class. This fungus lives its life in grasses and plants and thus infects cattle, in which animals it is comparatively frequent, causing the disease known as "lumpy jaw." These in turn affect man. See PARASITES.

In man the symptoms are often very obscure. Some infections of the lungs have appeared to be cases of pulmonary tuberculosis. Pathologically the disease is one of new connective tissue formation with abscess production. It is a chronic disease and often is a slow, suppurative affair affecting the tissues about the pharynx and neck. The bones, lungs, and intestinal tract may be affected. The diagnosis may be readily made by the microscope. Consult: Salmon, 'Investigation Relating to the Treatment of Lumpy-Jaw, or Actinomycosis in Cattle, Department of Agriculture Bulletin No. 2 (1893).

Actin'ophone, better known as the radiophone (q.v.)

Actinozo'a, or An'thozoa, a class of cœlenterates which exist only in the polyp state, not giving rise to a medusa form. They are represented by the sea-anemone (q.v.) and coral polyps. Their bodies are vase-shaped, usually fixed at one end, though most of them are capable of slowly moving about. They are provided with a digestive sac partially free from the body-cavity opening into it below, and held in place by six or eight mesenteries radiating from the digestive cavity and dividing the perivisceral space into chambers. The mouth is surrounded with a circle of tentacles, which are hollow, communicating directly with the perivisceral chambers. There is a slightly marked bilateral symmetry. To the edges of the mesenteries (usually the free ones) are attached the reproductive glands, both male and female, or of one sex alone; also the « craspeda,» or mesenterial filaments, which contain a large number of thread-cells (q.v.). The body is either entirely fleshy or secretes a calcareous or horny coral-stock, and when the species is social it is connected by a cœnenchyme. In some forms, as sea-pens (q.v.) the entire colony is capable of limited locomotion. There is no well-marked nervous system, but a plexus of fusiform ganglionic cells connected by nerve-fibres in the base of actinians. Reproduction takes place by self-division, gemmation, or by eggs, the sexes being separate or united in the same individual; the young undergoing a blastula and gastrula condition, and then becoming fixed.

The Actinozoa are divided into two sub-classes, the *Zoantharia*, and the *Alcyonaria* (qq.v.).

Action. *In law*, the formal demand of one's right from another person, made and insisted in a court of justice which has jurisdiction of the person and the subject-matter of litigation. In a quite common sense, action includes all the formal proceedings in a court of justice attendant upon the demand of a right made by one person, or party, of another in such court, including an adjudication upon the right, and its enforcement or denial by the court.

The parties to an action are called plaintiff and defendant, and the former is said to sue or prosecute the latter, hence the word suit instead of action. In some few instances the redress sought by a civil action consists in the recovery of some specific article of property wrongfully and unlawfully taken by the defendant from the plaintiff, but most frequently the object of an action is to obtain compensation in money for an injury complained of, which compensation is technically called damages.

The action is said to terminate properly at judgment.

Civil actions are those actions which have for their object the recovery of private rights, or of damages for their infraction.

Criminal actions are those actions prosecuted in a court of justice, in the name of the government, against one or more persons accused of a crime.

Transitory actions are those civil actions the cause of which might have arisen in one place or county as well as another.

Local actions are those civil actions the cause of which could have arisen in some particular place or county only.

Personal actions are those civil actions which are brought for the recovery of personal property, for the enforcement of some contract, or to recover damages for the commission of an injury to the person or property.

Real actions are those brought for the recovery of lands, tenements, and hereditaments. Mixed actions are those which partake of the nature of both real and personal actions.

In higher theoretical mechanics the word « action » is used to signify the value of a certain integral, whose form may vary according to the character of the problem in hand. In the case of a single particle the action is the space integral of the momentum of the particle, or it is double the time integral of its kinetic energy. In a system of such particles the total action is the sum of the actions of the constituent particles. It is probable that the physical principle corresponding to the mathematical expression called « action » will some day be exhibited to us in a simple form; but up to the present time no mathematician or physicist has succeeded in doing this. The importance of « action » as a mathematical conception may be seen from the following theorem, which has long been known: « If the sum of the potential and kinetic energies of a system is the same in all its configurations, then, of all the sets of paths by which the parts of the system can be guided by frictionless constraint to pass from one given configuration to another, that one for which the action is least is the natural one, and requires no restraint.» The theorem just stated is known as Maupertuis' « principle of least action.» There is also a principle of stationary action, and one of varying action; but it is impossible to elucidate these without a prohibitive amount of

mathematics. The last two principles were formulated by Sir William Rowan Hamilton.

In theoretical mechanics the word «action» is also used to signify a force acting upon a body, as in the expression «action and reaction.» See FORCE; MOTION, LAWS OF.

In applied mechanics the mechanism by which some operation is effected in a machine is often called the action of the machine; thus we speak of the action of a gun, meaning the mechanism governing the loading and firing of the gun; or of the action of a piano, meaning the combination of keys, hammers, and other parts, by which the player causes the strings of the instrument to vibrate.

In psychology. See EXPRESSION.

Actium, ak'shium, Greece, now **La Punta**, lä poon'ta: a promontory on the W. coast jutting out from the N.W. extremity of Acarnania, on the Ionian Sea at the entrance of the Gulf of Arta (old Ambricia), opposite Prevesa and just N. of Santa Maura (old Leucadia). Forts Punta and Aktium defend it. It represents one of the greatest of historical landmarks: the naval battle of 2 Sept. 31 B.C., between Octavianus (later the Emperor Augustus) and Antony, which decided the mastership of the then civilized world. For the reasons of the engagement, see ANTONIUS: it was fought by him, not for victory but for escape, which partly explains its half-heartedness and result on his side. Both armies were drawn up on the shore watching it. After waiting four days for a calm they engaged about noon on the fifth. Antony had some 500 large ships, Octavianus fewer and lighter ones. Antony on his right was opposed to Agrippa, Octavianus on his to Cælius; Cleopatra's 60 were in the rear. Antony's vessels were huge hulks, too clumsy for manœuvring; but on the other hand so impenetrable with iron-bolted timbers and brass plates and spikes that Octavianus' galleys dared not ram them for fear of shattering themselves, and skirmished rapidly around, hurling missiles and trying to board. It was more like the besieging of forts than a naval battle: one of Antony's tall structures being often surrounded with three or four of its nimble foes pouring darts and fire-balls into it, to which it replied from catapults loaded with heavy missiles. At length Agrippa used his superior numbers to attempt a flanking movement; Antony's flag-captain drew his wing away from the centre to prevent it: Cleopatra took alarm, and to make sure of escape her squadron broke through the front rank, throwing it into disorder, and sailed away for Egypt. Antony jumped into a small galley and followed her, leaving his command to its fate: even so it fought on till about 4 P.M., when 300 ships had been taken and many burned, and 5,000 men killed; it then yielded. The land army surrendered a week later. In commemoration of the triumph Octavianus enlarged the temple of Apollo at Actium, dedicated his trophies there, instituted quinquennial games, and built Nicopolis («city of victory») on the site of his army's camp, near the modern Prevesa. (Plutarch's ‹Life of Antony› is the only first-hand account in an English translation; and Dion Cassius, in Greek, is much later and less judicious.)

Active Constituents of Plants. See PLANTS.

Act of God, an accident which arises from a cause which operates without interference or aid from man. The term is sometimes used as equivalent to inevitable accident, but incorrectly according to some authorities, although Sir Wm. Jones proposed the use of «inevitable accident» instead of «act of God.»

Act of Settlement, an act of the Parliament of England in 1701, vesting the hereditary right to the English throne in Sophia, Electress of Hanover, and her Protestant descendants, constituting the source of the sovereignty of the House of Hanover or Brunswick, the present ruling line. The act prohibited the king (or queen) from going to war in defense of non-English powers without the assent of Parliament.

Act of Supremacy. (1) An act of the Parliament of England, in 1534, by which the king was made the sole and supreme head of the Church of England. (2) A re-enactment of the above, with changes, in 1559.

Act of Toleration, usually known as the TOLERATION ACT, an act of the reign of William and Mary, granting freedom of religious worship, under certain comparatively moderate conditions, to all dissenters from the established Church of England except Roman Catholics and persons denying the Trinity. This act, as confirmed in the reign of Anne, was the basis of various subsequent measures of religious toleration, culminating in the Catholic Relief Act of George IV. and the still more liberal legislation of Victoria.

Act of Uniformity. (1) An act of the Parliament of England (1559) adopting a revised liturgy for the Church of England, entitled «An Act for the Uniformity of Common Prayer and Service in the Church, and Administration of the Sacraments.» (2) An act of Parliament (1662) requiring that the revised Book of Common Prayer and Ordination of Ministers, and no other, should be used in all places of public worship and be assented to by clergymen. By this test more than 2,000 non-conforming clergymen were ejected from their churches. It took effect on St. Bartholomew's Day (24 Aug. 1662), and accordingly is known in English history as the «Bartholomew Act,» the day of its enforcement being known as «Black Bartholomew.»

Acton, John Emerich Edward Dalberg, baron, historian: b. Naples, 10 Jan. 1834; d. Bavaria, 19 June 1902. He was educated under Dr. (afterward Cardinal) Wiseman at Oscott College, England, and at Munich under Ignatius von Döllinger, whose friend and adherent he remained throughout life. He was returned to Parliament for Carlow (1859) and for Bridgnorth (1865), but was unseated on a scrutiny of the vote; created a peer (Baron Acton of Aldenham) in 1869 by Gladstone, whose trusted friend and adviser he was. A strong Liberal in politics and religion, he founded the ‹Home and Foreign Review› (1862–4) in the interest of the liberal Catholic party, and adopted the Home Rule idea before Gladstone himself. At the Œcumenical Council in Rome (1870) he vigorously opposed the dogma of papal infallibility. From 1895 to 1902 he held the office of regius professor of modern history at Cambridge Uni-

versity. A scholar of wide and vast erudition, his passion for acquiring knowledge seemed to act as a check upon his productive powers. No modern man of such first-rate abilities has left so few literary productions by which posterity may judge of those abilities. Between 1868-90 he gave to the press a few historical essays and anonymous letters; and in 1895 he published a ‹Lecture on the Study of History.› In 1882 he planned a comprehensive history of liberty, but never carried out the design. His university lectures were models of narrative, fulness of thought, and flawless exactitude of statement. ‹The Cambridge Modern History› (vol. 1, 1902) was planned and outlined by him.

Acton, Sir John Francis Edward, English adventurer, son of an English physician and a French lady: b. Besançon, France, bapt. 3 June 1737; d. Sicily, 12 Aug. 1811. Entering the Tuscan navy under his uncle's auspices, he commanded a frigate in the Algerian expedition of 1775, performed daring exploits in covering its retreat, and attracted the notice of Caramanico, favorite of Queen Caroline of Naples; and the queen, ambitious of playing a large European part, persuaded her brother, the Grand Duke of Tuscany, to lend Acton to her to reorganize her navy. He soon became her prime favorite, commander-in-chief by both land and sea, and ultimately prime minister, shelving Caramanico on foreign missions. He improved the roads and ports, but excited great discontent by the consequent taxation and the positions given to foreigners. In 1793 he formed the league between Naples, Austria, and England against France; in 1798 the French victories forced him to fly with the royal family to Sicily, and the Parthenopean Republic was formed. Five months later they were back, and he, with a «Junta of State,» instituted a reign of terror, sending many to the prison or the block. In 1804 he was removed at French demand, and in 1806, when the French entered Naples, he was obliged to take refuge in Sicily again, where he died with the ill will of all parties.

Acton, Thomas Coxon, American financier and public official: b. New York city, 23 Feb. 1823; d. there, 1898. He was a leading banker, and in early years was assistant to the county clerk, and deputy register; 1860-9 metropolitan police commissioner, 1862-9 president of the board. During the draft riots of July 1863 he commanded the entire police force in person for a week, rendering highly valuable service. He was superintendent of the United States Assay Office 1870-82, and assistant treasurer of the United States at New York 1882-6. He was always an active agent in administrative and social reforms in the city; carried through against bitter opposition the creation of a paid fire department; and assisted in founding the Society for the Prevention of Cruelty to Animals and the Society for the Prevention of Cruelty to Children. He declined a nomination for mayor.

Acts, Apocryphal. See Apocrypha.

Acts of the Apostles, fifth of the New Testament canon, and last of the canonical narratives of Christian origins: and, aside from the meagre notes in the Epistles, our one source of the history of Christianity for the first thirty or thirty-five years after the death of Christ. Immemorial tradition has assigned it to the author of the Gospel of Luke, and from the close resemblance of matter, tone, and evident purpose, modern criticism is inclined to validate this, though there are some discrepancies not easy to explain if so. In any case the author of each was a Gentile Christian, writing to explain to pagan Gentiles the origins of Christianity, and its spread by divinely directed methods from Jews to Gentiles; but the «Acts» is the later, showing some theologic development, very harsh toward the non-Christian Jews, and attributing all harassing of the apostles and resisting of the extension of the gospel to them and not the Gentiles, who in fact are called into the fold because the Jews will not listen. Both are anxious also to show that the Roman government from the first had no hostility to the new movement, and rather favored it but for Jewish pressure: Pilate admires and wishes to save Jesus; Paul's first converts are Roman officers, and the Roman magistrates find no crime in him and go out of their way to screen him from conspiracies. A further and strong object of the «Acts» is to show that the first Christians were of one heart and soul, without selfishness or jealousy and single in aim: they distribute their possessions and have all things in common; they accompany and take the tenderest farewells of each other; and there is no book with more beautiful and attractive characters,— Stephen, Cornelius, Lydia, the jailer at Philippi, etc. Hence too some of the divergences from the facts stated in other books, and presumably true as there was no motive for their invention, but the reverse: for instance, the bitter conflicts of Paul with the other heads, as told in Galatians and Corinthians. The apostles and Paul are the co-foundations of the Christian world, at God's will. But the notion that the book is a Pauline apology is contradicted by its matter: not only are conditions laid down for an apostle which would exclude Paul (i. 21 sqq.), but the narrator takes pains to show that Paul only followed in the footsteps of the apostles and originated nothing. The suppression of his wanderings in Arabia, Syria, and Cilicia makes it appear that Peter and not he gained the first Gentile convert; Peter's miracles duplicate his in remarkable number and exactness; and in nearly all cases, when Paul goes into a strange town to preach, he cannot gain the right till he has first attempted to preach to the Jews and been rejected by them, thereby forcing him to appeal to the Gentiles. In one place (xxviii. 17-28) the existence of a prior Christian Church is actually ignored to this end; and after Jesus' appearance to Paul he still has to be inducted into his work by human hands (Ananias and Barnabas), though the church at Antioch — the first Gentile Christian church and Paul's first important congregation — has already been founded by Christians from Jerusalem. The real hero of the book is the united, co-equal, self-abnegating band of God-sent Christian missionaries.

The title is probably not the original and certainly not the correct one: nine of the apostles are mentioned only by name, and James and John hardly more; while it is much fuller on several subordinate figures than on any others but Peter and Paul,— the deacons Stephen, Philip, Apollos, Cornelius, etc. It professes to

be the relation of an eye-witness, and in a portion of the narrative uses the personal "we"; but this relation — which is entirely trustworthy — forms but a small part of the book, and represents a document (probably a journal) by a companion of Paul, which the later actual writer used, in part bodily, in part as unavowed material, claiming its credit for his entire work. This is shown among other things by the excessive minuteness of the itinerary and other unimportant items in some cases, contrasted with the vague generality of others, its ignorance of the most important facts or traditions (the gift of tongues, for instance, and Paul's wanderings), or even categorical contradiction of others, as the contentions of Paul. Whether this is lack of knowledge or "tendency" writing, it equally shows the composite nature of the work; as do the discrepancies in relating the same facts: for example, in ix. 7, Paul's companions hear a voice but see no one; in xxii. 9 they see the light from heaven but hear nothing; in xxvi. 12–18 they fall down with Paul but nothing more is told. The other sources — oral traditions and lost works — doubtless enshrined much genuine history. The theory that it is a later recension of his own work by "Luke," from an earlier rough-draft represented by the "we" narrative, is not sustained.

The minimum date is approximately fixed by the fact that the author knows Josephus' works, which began with the "Jewish War," 79 A.D., and ended with his autobiography, shortly after 100; it cannot therefore be much earlier than 105, or if "Luke" knew Josephus also, about 110. The maximum is reckoned about 130; but curiously, Marcion, c. 140, had the Third Gospel but not "Acts," or if he had it he rejected it. In any event it is of the first half of the 2d century, which agrees also with its tone toward the Roman power. The "Good Emperors" reigned 96–180 A.D. The chief critical examinations are in German: H. Meyer (ed. Wende, Göttingen 1899); Ewald, 'The First Three Evangelists and the Acts of the Apostles' (Göttingen 1872).

Actuality, Law of, in philosophy, the state of being actual; reality. "The actuality of these spiritual qualities is thus imprisoned, though their potentiality be not quite destroyed."— Cheyne.

Actuarial Society of America, a scientific organization, established in April 1889, having for its object the promotion of actuarial science by such methods as may be found desirable. The membership is composed of those connected with actuarial pursuits. The enrollment is divided into members and associates. Candidates for associate are required to pass such preliminary examination as may be prescribed; a second examination is demanded of candidates for member. An annual meeting is held on the first Thursday after 14 May in each year. Other meetings may be called by the council from time to time and by the president at any time on the written request of 10 members. The officers of the society are a president, a first and second vice-president, a secretary, and a treasurer. President and vice-presidents are not eligible for the same office for more than two consecutive years. The council is composed of the officers and six other members, two elected to serve for three years, two for two years, and two for one year. The society publishes 'Transactions,' containing the proceedings of the meetings, including original papers presented by members or associates, discussions on said papers, and other matter expressly authorized by the council. On 1 June 1903 the total number of members was 123; that of associates, 29. Enrollment is not restricted to the United States. Office of the secretary, 32 Nassau Street, New York.

Actuary, in ancient Rome, a clerk of public bodies who recorded their *acta;* also one of the public reporters who prepared the daily news of the city as a written newspaper. (See ACTA DIURNA.) In modern times, the mathematician of an insurance company, who makes the calculations on which its policy plans and prices are based, and applies the doctrine of probabilities to fire, life, or accident insurance. Although the material on which he works is theoretically furnished by the experience of his and other cognate companies, and the records of public and private bodies, with the common rules of interest, in fact it needs not only great mathematical capacity but great practical sagacity to apply them to actual business; and no actuary of the highest class is a mere mathematician. In the early days, when experience was still mostly to make, the actuaries were usually the presidents of their companies; in recent times a safe body of experience has accumulated which enables business men to head them, and the actuary's computations and advice relate to slighter variations or special plans. In accident companies the actuary needs to be and usually is a man of large practical acquaintance with different employments, their hazards, the meaning of given employment-names, and those under which the more hazardous employments are disguised as less so; in fire insurance equally he must know the character of different risks. See INSURANCE.

Acuña, Manuel, ä-koon'yä, män-oo-el', Mexican poet: b. 1849; committed suicide 1873 from disappointed love, which was the principal theme of his poems.

Acuña de Figueroa, Francisco, ä-koon'yä dā fē-gā-rō'ä, frän-thēs'kō, Uruguayan poet: b. Montevideo, 1791; d. there, 6 Oct. 1862. His works are a Spanish-American classic from their metrical perfection, though deficient in warmth. The collection 'Poetic Mosaic' comprises every variety of secular and religious poetry, from heroic poems to psalms.

Adair', James, American 18th-century Indian trader and author. He lived 1735–75 among the Indians, mainly the Cherokees and Chickasaws; and in the latter year published a 'History of the Indian Tribes,' especially the southeastern ones, containing an admirable first-hand account of their manners and customs, and a still more valuable though unsatisfactory set of Indian vocabularies. But the chief object of writing the book was to trace the origin of the Indians to the Lost Tribes of Israel; a curious phantasm (especially as the tribes are known not to have been lost, and the differentiation of stocks must far antedate the Christian era) which has bewitched many enthusiasts since, and was revived and expounded by Dr. Elias Boudinot in his 'Star of the West' (1816). Adair's views are summarized in H. H. Bancroft's 'Native Races,' vol. 5, p. 91.

Adair, John, American general and public officer: b. Chester co., S. C., 1759; d. Harrisburg, Ky., 18 May 1840. He served in the Revolution; removed to Kentucky 1787; in 1791 was major under St. Clair and Wilkinson in the northwestern Indian expeditions, and was defeated by the Miami chief «Little Turtle» near Fort St. Clair. He was a member of the constitutional convention which made Kentucky a State, 1 June 1792; was State Representative and Speaker, register of the United States Land Office, and 1805–6 United States Senator. He was volunteer aid to Gen. Shelby at the battle of the Thames, 5 Oct. 1813; made brigadier-general of State militia Nov. 1814, and as such commanded the State troops at New Orleans under Jackson, 8 Jan. 1815. He was governor of Kentucky 1820–4, and United States Representative 1831–3, on the committee on military affairs.

Adair, Robin. See ROBIN ADAIR.

Ad'albert, or **Al'debert,** a native of France, who preached the gospel in 744 on the banks of the Main. He is remarkable as the first opponent to the introduction of the rites and ordinances of the Western Church into Germany. He rejected the culture of the Saints and Confession, but distributed his own hair as sacred relics to his followers; was accursed of heresy by Boniface the apostle of Germany, and condemned by two councils, at Soissons in 744 and at Rome in 745. Finally escaping from prison, he is said to have been murdered by some peasants on the banks of the Fulda.

Adalbert, St., of Prague, the apostle of Prussia proper: b. 939; d. 23 April 997. He was the son of a Bohemian nobleman, and his real name was Voitech («host — comfort»); was educated in the cathedral of Magdeburg, and appointed the second bishop of Prague in 983. He labored in vain to convert the Bohemians from paganism, and to introduce among them the ordinances of the Church of Rome. Discouraged by the fruitlessness of his pious zeal, he left Prague (988) and lived in convents at Montecasino and Rome until the Bohemians in 993 recalled him; but after two years he again left them, disgusted with their barbarous manners. He returned to Rome, and soon followed the Emperor Otho III. to Germany; on which journey he baptized, at Gran, St. Stephen, afterward king of Hungary. He proceeded to Gnesen to meet Boleslas, Duke of Poland. Being informed that the Bohemians did not wish to see him again, he resolved to convert the pagans of Prussia, but was murdered by a peasant near what is now Fischhausen. His body was bought by Boleslas for its weight in gold, and became famous for its miraculous power. Its influence was greater than that of the saint himself: the Bohemians, who had refused to receive the ordinances of the Church, now suffered them to be introduced into Prague, on the sole condition that these miraculous relics should be transferred to their city. They were rediscovered in a vault in 1880 and deposited in the cathedral. (Life by Heger, Königsberg 1897; Voigt, Berlin 1898.)

Adalbert, «The Great,» Archbishop of Bremen and Hamburg: b. about 1000; d. 17 March 1072; descendant of a Saxon princely house. He received his office in 1043 from the Emperor Henry III., whose relation, friend, and follower he was. He accompanied Henry to Rome in 1046 and was a distinguished candidate for the papal chair. Pope Leo IX. made him his legate in the north of Europe (1050). He superintended the churches of Denmark, Norway, and Sweden, converted the Wends, and aspired to a great northern patriarchate to vie with the Roman Curia. During the minority of Henry IV. he usurped, in concert with Hanno archbishop of Cologne, the guardianship of the young prince and the administration of the empire, and gained an ascendancy over his rival by indulging the passions of his pupil. After Henry had become of age Adalbert exercised the government without control in his name. His pride and arbitrary administration induced the German princes in 1066 to remove him by force from the court; but after a short contest with the Saxon nobles, who laid waste his territory, he recovered his former power in 1069, and held it till his death in Goslar in 1072. His injustice and tyranny were instrumental in producing the confusion and calamities in which the reign of Henry IV. was involved.

Adalia, Turkey in Asia, a seaport on the S. coast, in the vilayet of Konieh, finely situated on the Gulf of Adalia, from which the houses rise in terraces like an amphitheatre, on a rocky hill and surrounded by fig, orange, and mulberry gardens. It lies in a fertile but hot and unhealthy locality, producing grain, figs, oranges, wine, etc. It has a small but good port, and carries on a considerable trade; exporting grain, timber, cattle, valonia, etc. It was anciently called Attalia, later Satalia. Pop. about 30,000, 7,000 Greeks.

Adam («one made») and **Eve** («living being,» feminine). As the Old Testament almost invariably uses the article before «adam» («the adam» = «the made one» or «the man»), its use as a personal name is a mere misapprehension, and the implications drawn from it are no part of the text; nor is there any reason to suppose it was so intended by the writers who used it, or so understood by the Jews. This, however, is a minor point, as the narratives of the creation and fall, etc., have the same bearing whether the first created beings had names or not: they remain themselves no less. But those narratives were certainly not understood by their compilers themselves, who merely took them from Babylonian sources (see CREATION), as implying literal history,— which their discordance should render obvious,— and the difficulties involved in it result from being more Biblical than the Bible, as the Yahvistic portions of the later chapters disregard them, and the Yahvish adds to them at will. The accounts in Genesis are three: (1) The Elohistic (q.v.), in which «male and female» are created at the same time; that is, the whole race, just as the whole animal race is created at a stroke. The interpretation as «one couple» is thrown back from the second account. (2) The Yahvistic, in which «the adam» is made from the dust, and «the eve» from the adam; and which contains the theological part of the story,— the location in the Garden of Eden, the prohibition of God and its disregard, the expulsion, the birth of Cain and Abel, and the first murder. (3) The genealogical list in chapter v., where the race is

derived through Seth, and Cain and Abel are unknown; and where the first generations of men are demigods with enormous spans of life. The last is not only later than the other two, and corresponding to Greek, Assyrian, etc., pedigrees carrying the race or its first families back to the gods, but it is entirely unconnected with the first two, which have a certain relation as efforts of early man to account for the origin and propagation of life on the earth, which every race has undertaken as soon as it attained self-consciousness. The first, however, is that pure and simple, with no ulterior purpose. The second is quite other, combining the creation story of a single couple, the progenitors of the human race,— as with the Greek Deucalion and Pyrrha, etc.,— with a deeply moralized account of the origin of moral evil, and the rapine and violence, pain and disease and hardship, which it brought into a world previously free from them. It is this, reflecting the predominant religious tone of the Jewish mind, that has formed the basis first of the Jewish and then of its successor the Christian theology: Adam as the reason for and spring of human sin. This resulted in Paul's conception of two Adams: the fleshly one, whence come sin and death; and the spiritual one, whence springs salvation.

Most of the later Jews regarded the story as an allegory. Philo, the foremost writer of the Alexandrian school, explains Eve as the sensuous part, Adam as the rational part, of human nature. The serpent attacks the sensuous element, which yields to the temptation of pleasure and next enslaves the reason. Clement and Origen adapted this interpretation somewhat awkwardly to Christian theology. Augustine explained the story as history, but admitted a spiritual meaning superinduced upon the literal; and his explanation was adopted by the reformers, and indeed generally by the orthodox within the Catholic and the various Protestant Churches alike. More modern critics, loth to abandon it wholly as legend, have sought to separate a kernel of history from the poetical accretions, and attribute the real value of the story not to its form, but to the underlying thoughts. Martensen describes it as a combination of history and sacred symbolism, «a figurative presentation of an actual event.» The second narrative may be regarded as embodying the philosophy of the Hebrew mind applied to the everlasting problem of the origin of sin and suffering: a question the solution of which is scarcely nearer us now than it was to the primitive Hebrews. Hesiod describes man in his primitive state as free from sickness and evil before Prometheus (q.v.) stole fire from heaven, and Pandora (who corresponds to Eve) brought miseries to the earth. Prometheus gives man the capability of knowledge; his daring theft is for man the beginning of a fuller and higher life. Æschylus regards Prometheus as the representative of humanity led into misery by his self-will until he submits to the higher will of God. This corresponds with the story of Genesis, save that in the latter the spiritual features are clearer and more distinct.

Adam, Graeme Mercer, Canadian author and editor: b. Scotland 1839. He was trained in Blackwood's publishing house in Edinburgh, and, emigrating, became a publisher in Toronto and New York. He later edited several Canadian periodicals, assisted Goldwin Smith on the ‹Bystander,› and founded with him the ‹Canadian Monthly› (1872). In 1879 he founded the ‹Canadian Educational Monthly.› In 1896 he became editor of ‹Self-Culture.› He has written ‹An Outline History of Canadian Literature› (1886); ‹The Canadian Northwest› (1895); and with Ethelwyn Wetherald, the historical novel ‹An Algonquin Maiden›; etc.

Adam, Juliette, ad-äṅ, zhü-lē-et (MME. ADAM, née LAMBER), prolific Parisian journalist and author: b. Verberie, Oise, 4 Oct. 1836. She founded in 1879 the *Nouvelle Revue*, the organ of the Extreme Republicans, and edited it till her retirement in 1897; and her salon was a noted influence in Paris. Her second husband, Edmond Adam (later life senator, d. 1877), was prefect of police in Paris during the Prussian siege, and her first book was a diary of the siege. She has written largely (often under the pseudonyms Juliette Lamber and Comte Paul Vasili) on women's rights and various literary and social subjects; novels assailing Christianity for its crucifixion of natural instincts; ‹The Hungarian Fatherland› (1884), ‹General Skobeleff› (1886), etc.

Adam, Quirin François Lucien, ad-äṅ, kē-raṅ fräṅ-swä loo-seaṅ, French philologist: b. Nancy, 1833. His works, largely devoted to the study of primitive or savage tongues, have included among others American Indian subjects, as ‹Sketch of a Comparative Grammar of Cree and Chippeway› (2d ed. 1876); ‹Studies on Six American Languages› (1878); also ‹Grammar of the Manchouc Language› (1873); ‹Lorraine Patoises› (1881); ‹Negro-Aryan and Malay-Aryan Idioms› (1883).

Adam, Book of. See APOCRYPHA.

Adamant, a word loosely used to signify a substance of extreme hardness. It is probably derived from the Greek *adamas*, «unconquerable.» Very possibly the name adamant was at one time applied to a definite substance; but it has been used to signify corundum, various gems, a hard metal (probably steel) that was used in making armor, the lodestone, and various other substances. It is now chiefly used in a poetical or rhetorical sense.

Adamantine Spar, a name sometimes applied to corundum (q.v.) on account of its hardness; especially to the dark colored, non-transparent varieties which are used in pulverized form for polishing gems.

Adaman'toid, a crystalline form belonging to the isometric system, and bounded by 48 similar scalene triangles. It has 6 octahedral solid angles, at the extremities of the principal axes; 8 hexahedral solid angles, at the extremities of the trigonal axes; and 12 tetrahedral solid angles, at the extremities of the digonal axes. Its name is due to the fact that the diamond usually occurs in this crystalline form. (Also, and more commonly, called hexoctahedron.)

Adamawa, ä'da-mä'wa (formerly FUMBINA), an internally autonomous sultanate of central Africa, between lat. 6° and 11° N., and lon. 11° and 17° E.: part of the Sokoto empire in northern Nigeria; area some 50,000 sq. m. Much of the surface is mountainous, the mountains rising to about 8,000 ft. The princi-

pal rivers are the Benue and its tributary the Faro. The eastern part belongs to the German Kamerun; the western to British North Nigeria. A great part of the country is covered with thick forests, though there are also extensive and splendid pasture lands and cultivated fields. The native inhabitants are industrious and intelligent, but they have been in a great measure subdued by the Mohammedan Fulahs, who possess innumerable slaves. Slaves and ivory are the chief articles of trade. Pop. conjectured at 3,000,000. Chief towns, Yolo the capital, est. 12,000 to 20,000; Banjo, chief ivory mart; and Nganudere.

Adam Bede, the earliest of George Eliot's novels, was published in 1859 as « by the author of ‹ Scenes of Clerical Life. ›» A skeleton of the plot gives but a poor impression of the strength and charm of the story. It seems to have been, in the author's mind, a recognition of the heroism of commonplace natures in commonplace surroundings, of the nobility of noble character wherever found. But Adam Bede, intelligent, excellent, satisfactory though he is, is subordinated in interest to the figure of Hetty, made tragic through suffering and injustice. Dinah Morris, the woman preacher, is a study from life, serene and lovely. Mr. Irwine is a typical English clergyman of the early 19th century; Bartle Massey, the schoolmaster, is one of those humble folk, full of character, foibles, absurdities, and homely wisdom, whom George Eliot draws with loving touches; while Mrs. Poyser, with her epigrammatic shrewdness, her untiring energy, her fine pride of respectability, her acerbity of speech, and her charity of heart, belongs to the company of the Immortals.

Adam de la Hale, or **Halle**, ad-äṅ duh lä äl, French poet and composer: b. Arras about 1235; d. Naples about 1287· nicknamed the Hunchback of Arras, although he was not deformed. His satirical extravaganza, ‹ The Play of Adam, or The Play in the Arbor › (1262), constitutes the earliest comedy in the vulgar tongue; while the pastoral drama, ‹ The Play of Robin and of Marion,› may be looked upon as the earliest specimen of comic opera.

Adami, Friedrich, ä-dä'mē, frēd'rïн, German author: b. Suhl, 18 Oct. 1816; d. Berlin, 5 Aug. 1893. He wrote stories, plays, etc., a very popular biography of Queen Louise, and ‹ The Book of Emperor William › (1887–90).

Ad'ami, John George, English-American pathologist: b. Manchester, Eng., 1862; educated at Owens College there and Christ's College, Cambridge; studied at Breslau and Paris; became demonstrator of pathology at Cambridge in 1887; fellow of Jesus College 1891. In 1892 he came to Montreal as professor of pathology at McGill University; from 1894 has been head of the pathological department at the Royal Victoria Hospital there; from 1896 lecturer to the New York Pathological Society. He has published papers on pathological topics, and articles in Allbutt's ‹ System of Medicine.›

Adamine, a mineral better known as adamite.

A'damite (named for M. Adam, a French mineralogist), a mineral, isomorphous with olivenite, and occurring in small orthorhombic crystals that are often grouped in fine granular aggregations. It is an arsenate of zinc, having the formula $Zn_3As_2O_8.Zn(OH)_2$, although copper and cobalt may also be present. Its hardness is 3.5, and its sp. gr. 4.35. Its color is variable. It occurs at Cap Garonne, near Hyères, France; and also at Laurium, Greece, and in certain parts of Chile.

Adamites. (1) A Christian sect said to have existed in the 2d century: so called because both men and women appeared naked in their assemblies, either to imitate Adam in the state of innocence or to prove the control which they possessed over their passions. The tradition is probably baseless, originating in a name of derision given to the Carpocratians. (See GNOSTICS.) (2) Also called Picards, from the founder of their sect, Picard (perhaps also Beghards). He called himself Adam the Son of God, and advocated community of women. They appeared about the year 1421 on an island in the River Lusinicz, where Zisca surprised them, but was not able to destroy the whole sect. In the following year they were widely spread over Bohemia and Moravia, and especially hated by the Hussites (whom they resembled in hatred toward the hierarchy) because they rejected transubstantiation, the priesthood, and the Supper. They subsequently formed one sect with the remaining Taborites, who have accordingly been confounded with them. In 1849 a similar sect sprang up in Austria.

Ad'amnan, St. (dim. of Adam), an Irish ecclesiastic and author: b. in Donegal, c. 625; d. 703 or 704. He was descended from a cousin of St. Columba and from powerful Irish chieftains. Entering the monastery of Iona, he became abbot in 697; but was involved in quarrels with his monks over Easter and the tonsure (enforcing the orthodox Roman view against the Irish Church view), which hastened his death. He wrote a most valuable life of St. Columba (q.v.), the founder of Iona, full of historical information about the early Irish-Scotch Church (best edition Reeves', 1857; English translation in the ‹ Historians of Scotland,› 1874, reissued Oxford 1895); and a hearsay but valuable report of matters in Palestine in his time, the first we have of that land in the early Middle Ages.

Adam of Bremen, celebrated German historian: b. probably in Meissen, Saxony; d. 12 October of an unknown year, probably 1076. He lived at Magdeburg, removed to Bremen in 1067, was made canon of its cathedral and next year principal of the cathedral school. His fame rests on his ‹ History of the Church of Hamburg › (1072–6), an inestimable mediæval classic, for which he gathered material far and wide; making a special trip to Denmark to interview King Svend Estridson, whose communications he gives. As an appendix to his last book he gives an account of the Danish, Swedish, and Norwegian possessions, containing a passage of the first interest to Americans, as verifying the Saga stories of Vinland: « He [Svend] told of still another island found by many in that [Atlantic] ocean. It is called Wineland, because grapes grow there spontaneously. . . . I have learned through definite information from Danes that unsown crops also grow there in abundance.»

Adam of St. Victor, famous mediæval hymnologist: d. in Paris c. 1192; nothing is known of him save his great hymns, the most numerous of any mediæval writer, and among the foremost in rank. A few have been finely translated by J. M. Neale; a complete (so far as known) edition was published in London, 3 vols. 1881.

Adam Family, British architects, a celebrated 18th-century family consisting of William and his four sons, William, Robert, James, and John: of whom Robert ranks first and James next. The father was born in Fifeshire, Scotland, and his work was done in his native country: the town hall at Dundee, the library and university at Glasgow, and many other public and private buildings there and in Edinburgh, etc. Robert was born in Edinburgh, studied in Italy, and examined the noble remains of Dalmatia before settling in London: his work on Diocletian's palace at Spalato was a valuable advertisement to his talents and taste, and all the brothers increased their repute by publishing engravings of their plans. Under Robert's direction they constructed a great number of buildings in London,— the Adelphi Terrace and the streets around commemorates them specifically. He also did much to remodel the appearance of the city. Robert also built Lansdowne House, Kedleston Hall near Derby, and Register House near Edinburgh. A special feature of the brothers' work was their careful attention to harmonious interior arrangement and decoration.

Adam's Apple, in botany, (1) the name given by Gerard and other old authors to the plantain tree (*Musa paradisiaca*), from the notion that its fruit was that sinfully eaten by Adam in Eden. (2) The name given, for the same reason, to a species of *Citrus*.

In anatomy, a protuberance on the fore part of the throat, due to the thyroid cartilages. The name is supposed to have arisen from the absurd popular notion that a portion of the forbidden fruit, assumed to have been an apple, stuck in Adam's throat when he attempted to swallow it.

Adam's Bridge, or **Ra-ma's Bridge,** a chain of shoals across the Gulf of Manaar, between Hindustan and the island of Ceylon, in the Rāmāana fabled to have been constructed by monkeys.

Adam's Peak, one of the highest mountains in the island of Ceylon, about 45 m. E. of Colombo. It is of a conical shape, 7,420 ft. high, and can be seen in clear weather from sea 150 m. away. From its solitary position and immense height above the surrounding country the peak forms a striking and awe-inspiring object and has been for centuries venerated by the inhabitants. On the top, under a sort of open pagoda, is the sacred footmark, a natural hollow in the rock, artificially enlarged, and bearing a rude resemblance to a human foot. Mohammedan tradition makes this the scene of Adam's penitence after his expulsion from Paradise; he stood 1,000 years on one foot weeping for his sin, hence the mark. To the Buddhists, the impression is the *Sri-pada,* or sacred footmark, left by Buddha on his departure from Ceylon; and the Hindus recognize Buddha as an avatar of Vishnu or Siva. Devotees of all creeds here meet and present their offerings (consisting chiefly of rhododendron flowers) to the sacred footprint, finishing their devotions by a draught from the sacred well. The ascent of the mountain is very steep, and toward the summit is assisted by steps cut and iron chains riveted in the rock, the last 40 feet being accomplished by an iron ladder. The top is an area of 64 feet by 45.

Adams, Abigail Smith, wife of President John Adams: b. Weymouth, Mass., 23 Nov. 1744; d. 28 Oct. 1818. She was daughter of a Weymouth clergyman, who opposed the match and took for a text «My daughter is grievously tormented with a devil.» Though lacking strength and regular school education, she became a self-made force of high order in public affairs and one of the best of early American writers: her letters to her husband, collected and published, are not only of great historical and social value, but full of delightful genial humor and acute comment and judgment. Her husband's position kept them apart for years; but she joined him in France in 1784, went with him to his life of torment in London, and lived in Washington 1789–1801; thence till death at Braintree, now Quincy.

Adams, Alvin, founder of Adams Express Co.: b. Andover, Vt., 16 June 1804; d. 2 Sept. 1877. On 4 May 1840 he started an express business between Boston and New York which developed into the great company above named, formed in 1854 by the consolidation of several rival firms,— including Harnden's, the initiator of the express business,— with Mr. Adams as president. In 1850 he helped to organize the pioneer express service through the California mining camps, which on the consolidation above he sold out. In the Civil War the Adams Express Co. was of immense help to the government; in 1870 it extended its business to the far West.

Adams, Brooks, American social writer, son of Charles Francis: b. Quincy, Mass., 2 June 1848; was graduated at Harvard in 1870; and practised law till 1871. Besides magazine papers he has written ‹The Gold Standard,› ‹The Emancipation of Massachusetts,› a bitter assault on the Puritan theocracy (1887). ‹The Law of Civilization and Decay,› and (1900) ‹America's Economic Supremacy.›

Adams, Charles Baker, American naturalist: b. Dorchester, Mass., 1814; d. 1853. He was graduated at Amherst; assisted in the geological survey of New York, 1836; held scientific chairs in Amherst (1836–8), Middlebury College, Vt. (1838–47), and Amherst again (1847–53); State geologist of Vermont 1845–7. He wrote a geological text-book.

Adams, Charles Follen, American dialect poet: b. Dorchester, Mass., 21 April 1842; Union soldier; began writing broken German poems in 1872; author of ‹Leedle Yawcob Strauss, and Other Poems› (1878); ‹Dialect Ballads› (1887), etc.

Adams, Charles Francis, American statesman, son of President John Quincy: b. in Boston, 18 Aug. 1807; d. there 21 Nov. 1886. At the age of two he was taken by his father to St. Petersburg; in 1815 went with his mother thence to Paris; the same year his father was made minister to England, and he was placed in an English

boarding-school. In 1817 both returned to America; he was placed in the Boston Latin School, and in 1825 graduated at Harvard. His father had just been inaugurated President, and he spent two years in Washington; then returned to Boston, studied law with Daniel Webster, and was called to the bar in 1828, but never practised — engaging in literature and political writing in magazines and pamphlets, and editing John and Abigail Adams' letters (1840–1). He was Representative in the legislature 1841–4, State Senator 1844–6, as a Whig; heading the «Conscience Whig» wing, he edited the Boston *Whig*, 1846–8, was chairman of the Free-Soil Convention at Buffalo in 1848, and was nominated for Vice-President on the ticket with Martin Van Buren. In 1850–6 he edited John Adams' ‹Works› in 10 volumes. He joined the Republican party on its organization in 1855, and in 1858 was sent to Congress, and re-elected in 1860. In 1861 Lincoln sent him to England as minister, as his father and grandfather had been before him. But even their problems were trivial beside his, when the very existence of the Union perhaps depended on how far the English upper classes could drag the government in evasion of international obligations and covert help to the South. The seizure of Mason and Slidell on the Trent nearly precipitated war; the fitting out of cruisers to destroy United States commerce was put a stop to only after the escape of the Alabama (q.v.) in the face of Mr. Adams' representations, and his declaration to Earl Russell, then foreign secretary, that permitting the Laird rams also to leave Birkenhead was «war.» Napoleon III.'s persistent efforts to seduce the English government into a joint intervention in favor of the Confederacy had to be checkmated; and the rancorous hostility of one section and the coldness of the remainder of the best society made it a lonely and trying place, which for seven years he filled with a dignified resolution of immeasurable importance to his country. Returning to America in 1868, he was elected president of Harvard the next year, but declined: for several years, however, he was president of its board of overseers. In 1871 he was the United States representative on the board of arbitrators at Geneva to settle the Alabama Claims (q.v.); in 1872 he nearly obtained the nomination as Democratic-Independent candidate for the presidency, which Horace Greeley secured. In 1874–7 he edited the ‹Memoirs of John Quincy Adams› in 12 volumes.

Adams, Charles Francis (2d), American publicist, son of above: b. in Boston, 27 May 1835. He was graduated at Harvard in 1856, and served as a cavalry officer through the Civil War, rising from first lieutenant to colonel, and being brevetted brigadier-general at its close. Shortly becoming noted for ability in discussion of economic, political, and social questions, he was appointed railroad commissioner of Massachusetts in 1869; wrote ‹Chapters of Erie› (1871) in collaboration with his brother Henry, a series of papers on railroad accidents and on ‹The State and the Railroads› (1875–6) for the ‹Atlantic Monthly,› ‹Railroads, the Origin and Problems› (1878), ‹Notes on Railway Accidents› (1879), etc.; and 1884–90 was president of the Union Pacific Railroad Company. In 1892 he published ‹Three Episodes of Massachusetts History,› on the settlement of Boston Bay, the Antinomian controversy, and early town and church government, and in 1893 ‹Massachusetts: Its Historians and Its History.› In 1895 he was chosen president of the Massachusetts Historical Society, and in 1901 president of the American Historical Association. He has also written lives of Richard Henry Dana (1891) and of his father (1900, Am. Statesmen Series), ‹Lee at Appomattox,› etc. (1902), and much miscellaneous work. As chairman of the State Park Commission, 1893–5, he contributed materially toward planning out and establishing the great Metropolitan Park System of Massachusetts.

Adams, Charles Kendall, American historian and educator: b. Derby, Vt., 24 Jan. 1835; d. 26 July 1902. He removed to Iowa in 1855; graduated at the University of Michigan in 1861; became assistant professor there 1863–7, and professor of history 1867–85. He studied abroad 1867–8; in 1869–70 introduced the German seminary method into the United States by establishing the Historical Seminary in the University of Michigan; and was made dean of its School of Political Science when established. In 1885 he succeeded Andrew D. White as president of Cornell; resigned 1892, and till 1902 was president of the University of Wisconsin. He was chief editor of ‹Johnson's Universal Cyclopædia,› 1892–5. His most valued work is a ‹Manual of Historical Literature› (1882); he wrote also ‹Democracy and Monarchy in France› (1872); ‹Christopher Columbus› (1892); compiled ‹British Orations› (1884); and wrote much magazine and review matter.

Adams, Charles R., American tenor: b. Charlestown, Mass., 1848; d. 1900. He studied in Vienna, sang three years at the Royal Opera in Berlin, and nine in the Imperial Opera at Vienna. He was highly reputed as an interpreter of Wagnerian parts. In 1879 he settled in Boston, where he taught with great approval.

Adams, Edwin, American actor: b. 1834 in Massachusetts; d. in Australia, 1877. He first appeared as Stephen in ‹The Hunchback› at the Boston National Theatre, 29 Aug. 1853: played Hamlet at Wallack's (N. Y.) in 1860; starred in other cities, and returned to New York in 1866 as Robert Landry in ‹The Dead Heart›; was one of Booth's company when he opened his theatre 3 Feb. 1867, and played Mercutio and Iago, but won most fame as Enoch Arden.

Adams, Frank Dawson, geologist: b. Montreal, Can., 17 Sept. 1859; graduated at McGill University in 1878; took advanced courses at Sheffield Scientific School (Yale), and at Heidelberg, applying himself particularly to lithology and physical geology; in 1888 became lecturer on geology at McGill, and in 1893 succeeded Sir William Dawson as Logan professor of geology there.

Adams, George Burton, American historical writer: b. Vt. 1851. He is a professor of history at Yale; author of ‹Civilization During the Middle Ages› (1883), and ‹The Growth of the French Nation.›

Adams, Hannah, American literary pioneer: b. Medfield, Mass., 1755; d. 15 Nov. 1832. Her principal works were an ‹Autobiography›; ‹History of New England› (1799);

‹History of the Jews› (1812); besides several writings on religious topics. She lived in Brookline, Mass.

Adams, Henry, American historian, son of Charles Francis: b. Boston, 16 Feb. 1858. He was private secretary to his father during the latter's English ministry, and assistant professor of history at Harvard 1870–7, being reputed one of the most stimulating and original instructors as well as brilliant expositors in the country. With several pupils he published in 1876 ‹Essays on Anglo-Saxon Law,› of which he wrote on ‹Anglo-Saxon Courts of Law.› In 1871 he collaborated with his brother Charles Francis in ‹Chapters of Erie.› He edited the ‹North American Review,› 1875–6. In 1879 he published Albert Gallatin's writings (3 vols.); in 1882 a life of John Randolph (American Statesmen Series). But his life-work, and with one exception the foremost historical work of America in matter and style, is his ‹History of the United States from 1801 to 1817›—that is, the presidencies of Jefferson and Madison (9 vols. 1889–91): in motive a defense of his grandfather John Quincy Adams for deserting the Federalist party; in essence, a history of the causes and conduct of the War of 1812. For this he took up his residence in Washington and spent years ransacking its archives. He also lived for long periods abroad, examining various European records, and trained himself thoroughly in military and naval science and construction, besides studying historical and economic problems.

Adams, Henry Carter, economist: b. Davenport, Iowa, 31 Dec. 1852. He was graduated at Iowa College; afterward took a post-graduate course at Johns Hopkins, of which he became fellow and lecturer. Later a lecturer at Cornell, he is now professor of political economy and finance in the University of Michigan. He was statistician to the Interstate Commerce Commission, and had charge of the transportation department in the census of 1900. He has published works on public debts (1887), on taxation, political economy, industrial subjects, etc.

Adams, Herbert Baxter, historical student and educator: b. Shutesbury, Mass., 16 April 1850; d. 1901. He was graduated at Amherst in 1872; took Ph.D. at Heidelberg; and on the opening of Johns Hopkins in 1876 was made fellow in history, 1878 associate in history, 1883 associate professor in history, and in 1891, full professor. In 1901 he resigned on account of ill health, and died shortly after. In 1884 he was a leader in organizing the American Historical Association, and was secretary till 1900, then becoming first vice-president. He edited the ‹Johns Hopkins Studies in History and Political Science› from the start, also the ‹Contributions to American Educational History› published by the United States Bureau of Education. His chief publication is ‹The Life and Writings of Jared Sparks› (2 vols. 1893). Among his historical monographs are ‹The College of William and Mary,› ‹Thomas Jefferson and the University of Virginia,› ‹The Germanic Origin of New England Towns,› and ‹Maryland's Influence in Founding a National Commonwealth.› But his best work was not in writing history, but in training others to write it, and he was a powerful influence in creating the new school of historical research.

Adams, Isaac, inventor of the «Adams press» familiar to printers: b. in Rochester, N. H., 1803; d. 19 July 1883. He was a cotton-mill hand, then cabinet-maker, then machinist. His press—its essence consisting in the raising of the bed against a stationary platen instead of bringing the platen down on the bed—was patented in 1828, and much improved in 1834. He was a member of the Massachusetts Senate in 1840.

Adams, John, 2d President of the United States: b. Braintree, Mass., of a line of farmers, 19 Oct. 1735; d. July 4 1826, the year after his son was inaugurated President. Graduated at Harvard, he taught school, and read theology for a Church career; but seeing his unfitness for it studied law and began practice in 1758, soon becoming a leader at the bar and in public life. In 1764 he married his famous wife. All through the germinal years of the Revolution he was one of the foremost patriots, steadily opposing any abandonment or compromise of essential rights; and in 1766 published essays in the Boston *Gazette*, reprinted in London 1768, entitled ‹A Dissertation on Canon and Feudal Law,› really on colonial rights. In 1765 also he was counsel for Boston, with Otis and Gridley, to support the town's memorial against the Stamp Act. In 1766 he was a selectman, or in other words one of the three official rulers of the head of the New England colonies. In 1768 the royal government offered him the post of advocate-general in the Court of Admiralty,—in fact a lucrative bribe to desert the opposition; but he refused it. Yet in 1770, as a matter of high professional duty, he took his future in his hands to become counsel (successfully) for the British soldiers on trial for the «Boston Massacre.» Though there was a present uproar of abuse, Mr. Adams was shortly after elected Representative to the General Court by more than three to one. In March 1774 he was contemplating writing the ‹History of the Contest between Britain and America.› June 17 he presided over the meeting at Faneuil Hall to consider the Boston Port Bill, and at the same hour was elected delegate to the first Congress at Philadelphia (1 September), by the Provincial Assembly held in defiance of the government. Returning home, he was made a member of the Provincial Congress, already organizing resistance to England. Just after Lexington he again journeyed to Philadelphia to the Congress of May 1775; where he did on his own motion, to the disgust of his associates and the reluctance even of the Southerners, one of the most important and decisive acts of the Revolution,—induced Congress to adopt the forces already gathered in New England as a national army and put George Washington at its head, thereby engaging the Southern colonies irrevocably in the war and securing the one man who could make it a success. In 1776 he was a chief agent in carrying the Declaration of Independence. He remained in Congress till November 1777, serving on the Committee on Foreign Relations and as chairman of the Board of War and Ordnance, very useful and laborious, but making one dreadful mistake: he was largely responsible for the policy of ignoring the just rights and decent dignity of the military commanders, which lost the country some of its best officers and led ultimate-

JOHN ADAMS,

SECOND PRESIDENT OF THE UNITED STATES.

ly to Arnold's treason. His reasons, exactly contrary to his wont, were sound abstract logic, but thorough practical nonsense.

In December 1777 he was appointed commissioner to France to succeed Silas Deane. Dr. Franklin and Arthur Lee were there before him; and though he reformed a very bad state of affairs, he thought it absurd to keep three envoys at one court and induced Congress to abolish his office, returning in 1779. Chosen a delegate to the Massachusetts Constitutional Convention, he was called away from it to be sent again to France. There he remained as Franklin's colleague, detesting and distrusting him and the foreign minister Vergennes, embroiling himself with both, and earning a cordial return of his warmest dislike from both, till July 1780. He then went to Holland as volunteer minister, and in 1782 was formally recognized as from an independent nation. Meantime Vergennes intrigued energetically to have him recalled, and did succeed in tying his hands so that but for his contumacious stubbornness half the advantages of independence would have been lost, as Vergennes was employed to gain points for France and not for the United States. In the final negotiations for peace he persisted (against his instructions) in making the New England fisheries an ultimatum, and saved them. The wretched state of American affairs under the Confederation made it impossible to do his country any good abroad, and the vindictive feeling of the English made his life a purgatory, so that he was glad to come home in 1788.

In the first Presidential election of that year, he was elected Vice-President on the ticket with Washington; and began a feud with Alexander Hamilton, the mighty leader of the Federalist party and chief organizer of our governmental machine, which ended in the overthrow of that party years before its time, and had momentous personal and literary results as well. As official head of the party he thought himself entitled to its real leadership as well; Hamilton would not and indeed could not surrender his position, for the lesser men looked to him for counsel and policy, and the rivalry never ended till Hamilton's death. In 1796 he was elected President against Jefferson, and his term is recognized as one of the ablest and most useful of our administrations; but its personal memoirs are most painful and scandalous. The members of the Cabinet— nearly all Hamiltonians — laid official secrets before Hamilton and took advice from him to thwart the President. They disliked Mr. Adams' overbearing ways and obtrusive vanity,— for modesty or a low sense of personal dignity were no parts of his character,— considered his policy destructive to the party and injurious to the country, and felt that loyalty to them involved and justified a disloyalty to him. Finally his best act brought on an explosion. The French Directory had provoked a war with this country, which the Hamiltonian section of the Federalist leaders and much of the rank and file hailed with delight, thinking it a service to the world to cripple France as then ruled; but when it showed signs of a better spirit, Mr. Adams, without consulting his Cabinet (who he knew would oppose it nearly or quite unanimously), nominated a commission to frame a treaty with France. He had the constitutional right to do so; but the storm of fury that broke on him from the party has rarely been surpassed in the case of traitors outright, and he was charged with being little better. He was renominated for President in 1800, but beaten by Jefferson, owing to the defections in his own party, largely of Hamilton's producing. The Federalist party never won another election; the Hamiltonians laid its death to Mr. Adams, and American history is hot with the fires of this battle even yet.

His later years were spent at home, where he was always interested in public affairs and sometimes much too free in his comments on them; where he read immensely and wrote somewhat. He heartily approved his son's break with the Federalists (see ADAMS, JOHN QUINCY) on the Embargo (q.v.). He died on the same day as Jefferson, both on the 50th anniversary of the Declaration of Independence.

Mr. Adams' greatest usefulness and popularity sprang from the same cause that produced some of his worst blunders and misfortunes: a generous impulsiveness which which made it impossible for him to hold his tongue at the wrong time and place for talking, his vehemence, self-confidence, and impatience of obstruction. He was fervid, combative, opinionated, and masterful, and naturally won more hate than love; but he had trust, admiration, and respect from the majority of his party at the worst of times, and history justifies it. ('Works,' by his grandson Charles Francis Adams.)

Adams, John, American educator: b. Connecticut, 1772; d. 1863. Graduated at Yale in 1795, he was a school-teacher till 1810, and thence till 1833 principal of Phillips Academy, Andover, Mass., which he developed into repute throughout the country. He was teacher of Oliver Wendell Holmes, who, in the lines beginning «Grave is the Master's look,» commemorates him in his poem 'The School-Boy,' read at the Phillips Academy centennial in 1878.

Adams, John, Confederate soldier: b. Tennessee, 1825; d. 30 Nov. 1864. He was graduated at West Point in 1846; was brevetted first lieutenant for bravery at Santa Cruz de Rosales, 1848; promoted captain of dragoons, 1856; and resigned 1861 to join the Confederate army, in which he rose to the rank of brigadier-general. He was killed at the battle of Franklin, Tenn.

Adams, John, the name assumed by Alexander Smith, one of the mutineers of the Bounty. After intoxication and massacre had killed off all the mutineers but himself, he was shocked into a complete change of heart, and became sincerely pious and of upright life; he was the patriarch of the little native and half-caste group on Pitcairn's Island, taught a school and held worship there. It was nearly twenty years after the mutiny before his existence was known; and though technically liable to execution for the mutiny the English officials felt that his hardships, exile, and repentance had atoned for the crime, and that it would be wrong to remove the head from the little settlement. He was left unmolested and died in 1829. See BLIGH, WILLIAM; PITCAIRN'S ISLAND.

Adams, John Couch, English astronomer: b. in Cornwall, 5 June 1819; d. 21 Jan. 1892. A precocious mathematician, he became senior wrangler at St. John's College, Cambridge, and

mathematical tutor there. He discovered in 1845, by calculation of the perturbations of Uranus, that another planet must exist beyond it, and fixed its position within two degrees; but search for it not being made, Leverrier of Paris independently made the same discovery next year, and Galle of Berlin at once found the planet (see NEPTUNE). In 1851 he became president of the Royal Astronomical Society; 1858–9 professor of mathematics at Aberdeen University; 1859–92 Lowndean professor of astronomy and geometry at Camridge, and in 1861 director of Cambridge Observatory. He was a delegate to the International Prime Meridian Conference at Washington 1884.

Adams, John Quincy, 6th President of the United States, son of John Adams: b. in Braintree, Mass., 11 July 1767; d. Washington, D. C., 23 Feb. 1848. At 10 he accompanied his father on his first embassy to France, and was placed at school near Paris. He returned with his father in about 18 months; but soon went back with him to Europe, and attended school in Holland and at the University of Leyden. At 15 Francis Dana, his father's secretary of legation, who had been appointed minister to Russia, took him with him as his private secretary. After 14 months' stay in Russia, where Catherine refused to recognize Mr. Dana, he traveled back alone through Sweden and Denmark to The Hague. Soon after his father's appointment as ambassador at London in 1785, he returned home to complete his studies, as he believed « an American education to be the best for an American career,» a coolly judicious choice for a lad of 18. He graduated at Harvard in 1788, entered the office of Theophilus Parsons (q.v.), and in 1791 was admitted to the bar. He now began to take an active interest in politics. He wrote a series of letters to the Boston *Sentinel* under the signature of « Publicola,» in reply to Paine's « Rights of Man,» and in 1793 defended Washington's policy of neutrality under the signature of « Marcellus.» These letters attracted attention, and in 1794 Washington appointed him minister to The Hague. In 1798 he received a commission to negotiate a treaty of commerce with Sweden; and traveling through Silesia wrote an account of it which was published in London, and later translated into German and French. On Jefferson's accession to the presidency he was recalled and resumed law practice.

In 1802 he was sent to the State Senate; the next year to the United States Senate in place of Timothy Pickering, leading Hamiltonian. But the Hamilton-Adams feud (see ADAMS, JOHN) had split the party into rancorously hostile halves, and Mr. Adams was practically « boycotted » by the dominant section of his own party, as being an Adams, with an ingenuity of indecent insult curious to read of; still worse was it when Pickering was made his colleague by the other faction at the next vacancy. It was good training for the great career of his later life; he was not the man to conciliate his foes, and soon made the breach irreparable by breaking away from the party policy. Through life any action which strengthened the United States, or increased its dignity in the eyes of the world, or simply « showed fight » for any purpose, met with his heartiest approval and warmest support, even though fathered by his worst enemies; and he first supported (with some reservations) Jefferson's Louisiana purchase,— precisely in the line of the former Federalist policy and the nature of the party, but now fought by them as Jefferson's,— and in 1807 took a far more radical step. The action of France and Great Britain in plundering American commerce for evading their mutual blockade laws, and of the latter for impressing American citizens under pretense of their being English runaways, had enraged the country, but it was helpless against both and felt not strong enough at the time to fight either; finally the outrage of the Leopard on the Chesapeake (see the latter name) roused the Republicans to fury, and even many of the Federalists. But the leaders of the latter sympathized with England's difficulties in the war with Napoleon, would do nothing to embarrass her, and even defended the Leopard's action. Mr. Adams was as hot as any Republican; he tried to have the Boston Federalists hold a meeting and pledge the government their support in any measures to curb British insolence, and on their refusal attended a Republican meeting and was put on a committee to draft such resolutions. The Federalists were soon compelled by popular feeling to do likewise, and Mr. Adams also drafted resolutions there. At the extra session of Congress in October the Embargo on all American shipping was passed, to see if England could not be starved into better behavior; half ruining New England, most of whose capital was invested in commerce, and injuring Americans much more than the enemy. Mr. Adams was a member of the committee which reported the bill, and earnestly advocated it,— not because it went as far as he liked, but as preferable to showing no resentment whatever, and all the Federalists would permit. The execrations leveled at his father for the French mission, and the charges of sectional and party treachery, were repeated on the son; political literature for half a century was glowing with the acrid polemics on the subject, and the prime object of his grandson Henry Adams's ‹History› is to exculpate him. His term in the Senate was to expire 3 March 1809; in the preceding June the Massachusetts legislature elected James Lloyd to succeed him, as an insult, which he accepted and at once resigned. Meantime he had been made professor of rhetoric at Harvard and delivered lectures there. The next month he declined a Republican nomination to the House.

On Madison's accession in 1809 he at once appointed Mr. Adams minister to Russia; the Senate for some months refused to confirm the nomination, but at length yielded, and he pass 4½ years there. In the peace negotiations with England over the War of 1812, he was a commissioner with Gallatin and Bayard, and again defeated assaults on the American fishing rights like his father. The treaty is usually considered a humiliating fiasco for America; but it is significant that the British press considered it a surrender on their side, and especially reviled Mr. Adams for his share in it. Visiting Paris, he was made commissioner to negotiate the American-English commercial treaty signed 13 July 1815. Meantime he had arrived in England, 26 May, and received the news of

JOHN QUINCY ADAMS,

SIXTH PRESIDENT OF THE UNITED STATES.

his appointment as minister to that country. The synchronisms of wars, treaties, and ministerships between father and son is so curious that in ancient history it would be treated as indubitable confusion of persons.

Eight years later, after leaving America, Mr. Adams was recalled to it as Secretary of State under Monroe, inaugurated March 1817. His greatest achievement was the treaty with Spain ceding Florida to the United States for $5,000,000, to be used in paying American claims against Spain; and rectifying the boundaries of Louisiana and Mexico. His utter independence of personal against national considerations is singularly shown in his support of Jackson for invading Spanish Florida and hanging Arbuthnot and Ambrister; he hated and despised Jackson, and the latter had violated all international law; but he had roughly vindicated United States rights and put down dangerous intrigues with savages, and Mr. Adams vigorously defended him. He was the author of the « Monroe Doctrine,» and though he never dreamed of its later interpretations would not improbably have sympathized with them. He also drew up a report on weights and measures which is still a classic, and shows an almost incredible amount of investigation. An ultimately far more important question came up over the admission of Missouri as a slave State. The Missouri Compromise (q.v.) had been passed and put before Monroe for signature, but he submitted to his Cabinet the questions whether Congress had a constitutional right to prohibit slavery in a Territory, and whether the prohibition of slavery « forever » in the territory north of Mason and Dixon's Line meant while it remained a Territory or thereafter. The Cabinet was unanimous in the affirmative on the first question; Mr. Adams was alone in declaring that « forever » included statehood also.

In the presidential election of 1824 there was no electoral majority: Andrew Jackson had 99, Mr. Adams 84 (a remarkable vote considering his ungracious manner, gift for making enemies, and refusal to do anything to promote his election), William H. Crawford 41, and Henry Clay 34. Crawford was put out of the field by a paralytic stroke. As Clay could not be elected, his supporters cast their votes for Adams as preferable to Jackson: the former represented the same public policy as theirs, he was the ablest public official in the country and not personally hostile to Clay, while Jackson was regarded as an ignorant and violent demagogue. Mr. Adams was elected, and made Clay secretary of state, a place to which Clay's talents and position gave him almost a prescriptive claim. The Jacksonians denounced this as a corrupt bargain to defeat the people's will, and absurdly gave it the name of the unsavory English «Coalition,» a catchword which was an efficient party weapon for many years. Mr. Adams' administration had no dramatic events. Its policy was based on a new division of parties. The Federalists were dead, consequently their opponents were dead also, and the new division was into National Republicans, afterward Whigs, and Democratic-Republicans, or Democrats: the former favoring internal improvements, a national bank, and high tariffs, the latter opposing them. In reality, the division was between the preferences of the capitalist class and the masses. The Adams administration was Whig, and had the hostility of the Northern commercial classes whose trade the tariff was intended to cut down, and of the Southern planters who would lose as consumers while having nothing to protect as producers. Still more effectively the Jacksonian party, steadily and rapidly growing, used the promise of « spoils » to gain support; and in 1828 Mr. Adams was defeated for re-election by 178 to 83.

Mr. Adams retired, as he supposed, from public life. But in 1831 the constituency of his district around Braintree elected him a member of Congress on the Anti-Masonic ticket (see ANTI-MASONRY; MORGAN, WILLIAM); and though that party soon died, his immense ability and unique power in Congress kept him there till his death. By a singular fortune, he owes by far his greatest fame to this relatively small position after his crowning office was laid down. Belonging to no party, a political Ishmaelite, of the loftiest patriotism and the highest integrity, but scornful of nature and irritable in temper, rousing every demon of hatred in his fellow-members, in constant and envenomed battle with them and more than a match for them all, the « old man eloquent » was for many years a storm centre of wonderful picturesqueness. But his repute is not a mere political curio: he had the fortune to take his place at the very outset of the struggle of the slave oligarchy to suppress free speech and writing on the slavery question, and crush political liberty to uphold slavery. He fought the attempt unflinchingly year after year by purely legal methods, upholding the right of petition as indefeasible under any government or for any purpose,— he did not hesitate to submit a petition from Virginians praying for his own expulsion as a nuisance,— and consequently a right of slaves or of others in their interest; and with little sympathy for the anti-slavery cause as such, became by force of circumstances its mightiest champion. He died of a stroke of apoplexy on the floor of the House.

Adams, John Quincy (2d), American politician, son of Charles Francis; b. in Boston, 22 Sept. 1833; d. 14 Aug. 1894. He was graduated at Harvard in 1853, and became a lawyer. A Democrat after the war, he took hopeless candidacies for the governorship to keep the organization together, in 1867 and 1871, and for the vice-presidency in 1872. He also served in the legislature in 1866, 1869, and 1870. In 1877 he was made a member of the corporation of Harvard.

Adams, Julius Walker, American civil engineer: b. in Boston, Mass., 18 Oct. 1812; d. 13 Dec. 1899. Took part of the course at the United States Military Academy; was engaged for many years on railroad and waterworks construction, and planned the sewerage system of Brooklyn, N. Y.; was colonel of the 67th N. Y. Vols. in the Civil War; and was the pioneer engineer of the East River bridge.

Adams, Maude Kiskadden, American actress: b. in Salt Lake City, 11 Nov. 1872; daughter of an actress who was leading woman of a stock company in that city, under the stage name of Adams. At 16 Miss Adams joined

E. H. Sothern's company in the ‹Midnight Bell›; afterward she was in Charles Frohman's stock company, and later supported John Drew. She made a great success in J. M. Barrie's ‹Little Minister› in 1898, as Lady Babbie, and in 1900 as the Duc de Reichstadt in Edmond Rostand's ‹L'Aiglon.› She played Juliet in 1899, and Miss Phœbe in Barrie's ‹Quality Street› in 1901.

Adams, Nehemiah, American Congregational clergyman: b. in Salem, Mass., 19 Feb. 1806; d. 6 Oct. 1878. He graduated at Harvard in 1826, and at Andover Theological Seminary in 1829. The same year he settled at Cambridge, but 1834–70 was pastor of the Essex Street Church in Boston, and was widely reputed for his eloquence and learning. He published several polemic works; the most sensation was created by ‹A South Side View of Slavery,› published in 1854 after a winter in Georgia, in which he lauded slavery as beneficial to the negroes' religious character.

Adams, Parson (Abraham), one of the heroes of Fielding's ‹Joseph Andrews,› and the only creditable character in it except the heroine. He is a huge-framed, simple-souled, great-hearted, utterly disinterested innocent, a brother of Don Quixote, Colonel Newcome, and Uncle Toby.

Adams, Samuel, American patriot: b. Boston, 27 Sept. 1722; d. 2 Oct. 1803. He was son of a rich merchant, ship-owner, and magistrate, a leader in provincial contests with royal governors, and inventor of the caucus in fact and perhaps unintentionally in name. Educated at the Boston Latin School, he graduated at Harvard in 1740. In 1743 he wrote for his master's degree a thesis upholding the lawfulness of resisting supreme magistrates. He became a lawyer; but the profession was under ban with the upper classes, and at his family's wish he entered a leading merchant's counting-house. Shortly afterward his father set him up in business, in which he lost half his capital, losing the other half by a loan never repaid. Then he became partner with his father in a rather unsuccessful brewery. Soon the father lost nearly all his property in a land-bank scheme crushed by an act of Parliament, which extended an English banking enactment to the colonies. The hundreds of ruined shareholders denounced this act as an invasion of chartered colonial rights, and it turned the cream of the business leaders of Massachusetts, and their sons and daughters, into potential rebels at a blow. On his father's death in 1748 he carried on the brewery alone, and was nicknamed by his opponents «Sammy the maltster,» changed to «Sammy the publican» when he was made tax-collector of Boston 1763–5. Meanwhile he had become a great power in town meetings, having strong and sincere democratic feeling and a marvelous genius for political management and «caucusing.» As collector he was a bad business manager and was sharply assailed; but his political headship is shown by his being selected in 1764 to draft the town's instructions to its representatives relative to the Stamp Act,— the first public American protest against the parliamentary right of taxation,— and the like instructions the next year. He was himself in the legislature 1765–74, being clerk of the House and on the leading committees, drawing up the most important state papers of that stormy time, and spokesman as well as prompter of the incessant wrangles with Govs. Bernard and Hutchinson. When the Townshend Acts were passed in 1767, he drafted the legislature's petition to the king, the instructions to the Massachusetts agent in England, and the circular letter of February 1768 to the other colonies asking their aid. The latter led directly to the Revolution, George III. ordering Bernard to command the legislature to rescind it or be instantly dissolved. The latter refusing by 92 to 17, the king thereon resolved to send troops to overawe the colony. The same year Adams wrote ‹The True Sentiments of America,› and in 1769 a famous ‹Appeal to the World.› The morning after the «Boston Massacre» he was made chairman of a committee to communicate to Gov. Hutchinson and his council the town-meeting vote that the two regiments of British soldiers should be removed to the castle in the harbor. When the governor wished to compromise on one, Adams had the people insist on «both or none,» and both were removed, thereafter being known in Parliament as the «Sam Adams regiments.» In 1772 the order was issued that the judges should thereafter be paid by the Crown, not by the colony, and be removable at the king's pleasure: the Boston town-meeting requested Gov. Hutchinson to convene the legislature on the question, and on his refusal Mr. Adams revived a proposal of Jonathan Mayhew's in 1765, to have the towns of Massachusetts appoint committees of correspondence to consult about the common weal. Eighty towns soon adopted the suggestion, forming an omnipotent revolutionary legislature beyond the reach of government veto or dissolution, yet quite within the law. The next spring intercolonial committees of the same sort were formed,— an unorganized government of the united colonies. Meanwhile Mr. Adams had kept the public spirit inflamed and alive to the nature of the crisis by articles under various pseudonyms in the Boston *Gazette,* arguing the colonists' legal rights and the practical impossibility of any compromise; thus not only preparing the public for the crisis and bringing over the waverers, but making the crisis itself more inevitable. The management of the tea-ship matter was in the hands of the committees of correspondence of Boston and five adjoining towns, of which Mr. Adams was the active head; and the throwing of the tea into the harbor, 17 Dec. 1773, was unquestionably supervised or arranged by him. When as a punishment the port of Boston was closed and the charter of Massachusetts annulled in April 1774, and the legislature met at Salem under parliamentary order to abase itself and undo its bad work, Mr. Adams locked the door, pocketed the key, and carried through the measures for calling a congress at Philadelphia in September; the legislature adjourned *sine die* while the governor's clerk was hammering at the door with the writ of dissolution, and British authority was at an end. Mr. Adams' lifework — of assuring the breakdown of a system difficult to work at best, the government of a country by scornful aliens plus the aristocratic native families — was over. Though a useful and upright public servant, he was of secondary importance in presence of large problems of constructive statesmanship: his abilities were parochial, and

he does not figure on a national scale. He could manage caucuses and organize jealousies, but hardly frame constitutions. At the Philadelphia Congress he was of course a delegate, and greatly smoothed over sectional distrusts by his shrewdness, tact, and geniality. In 1775 he and Hancock were the only patriots excepted from amnesty; and it was Gage's attempt to seize them — under government orders, and with London forecasts that their heads would soon adorn Temple Bar — that brought on the battle of Lexington and opened the Revolutionary War. They escaped by Paul Revere's warning. He led in pushing forward the Declaration of Independence, of which he was one of the signers; and was active in Congressional work till the close of the Revolution. With much creditable service, his sympathies were always with division of authority; he believed in committees instead of executive heads, and national policy was often affected disastrously by the delays and irresponsibility involved. He was largely instrumental in framing the State Constitution of 1780. Nationally, he was of course an Anti-Federalist, opposing a strong national government in fear of tyranny: after long hesitancy over supporting the Constitution of 1787, he did so only on the understanding that amendments constituting a bill of rights should be submitted; but his voice in favor of ratification by Massachusetts secured it by 187 to 168, and saved it to the nation. He was long on the Executive Council of Massachusetts, lieutenant-governor 1789–94, and governor 1794–7 (three terms).

Adams, Suzanne, American lyric soprano: b. Cambridge, Mass., 28 Nov. 1873; studied with Marchesi at Paris: made her début 1894 at the Opera, as Juliet in Gounod's «Romeo and Juliet.» After three years there she went to Nice, then to Covent Garden in London, then (1898–9) to the Metropolitan Opera House, New York. She married Leo Stern the violoncellist in 1899. She has sung in many operatic soprano parts.

Adams, William, the first Englishman in Japan: b. Kent, c. 1575. In 1598 he sailed as pilot of five Dutch vessels from the Texel to the East; landing at Kiushiu, the great Shogun Iyéyasu, who had shortly before crushed his rivals and ended Japan's feudal anarchy, first imprisoned and then took him into service, employing him in shipbuilding, as informant, etc. In 1613 other Englishmen came on the Clove, and with Adams started a factory at Firando, of which Richard Cocks was chief. Iyéyasu dying in 1616, a reaction against foreigners set in, and Adams wished to return to England, where he had left a wife and children; but was forbidden, and married a Japanese wife, their descendants still living in Japan. He died 16 May 1620. "Pilot Street" in Yedo (Tokio) was named after him.

Adams, William Henry Davenport, English journalist and critic: b. 1851; d. London 27 July 1904. He published 'A Dictionary of English Literature' (1878); 'The Witty and Humorous Side of the English Poets' (1880); 'By-Ways in Bookland' (1888); 'A Book of Burlesque' (1891); 'With Poet and Player' (1891).

Adams, William Taylor, American author and editor, best known by the pseudonym "Oliver Optic": b. Medway, Mass., 30 July 1822; d. 27 March 1897. He taught for many years in the Boston schools. He was a voluminous and highly popular writer of fiction for young readers, his works including over 100 volumes, mainly travel and adventure: 'Young America Abroad,' 'Starry Flag Series,' and others.

Adams, Mass., town in Berkshire County, containing villages of Adams (formerly South Adams), Maple Grove, Zylonite, and Renfrew; the first and chief 16 m. N. of Pittsfield, 6 m. S. of North Adams, which was set off in 1878; on Pittsfield & N. A. branch of the Boston & A. division of the New York Cent. R.R. It is on Hoosac River, and contains Greylock Mountain, the highest point in Massachusetts. Founded in 1749 as East Hoosuck, it was renamed for Samuel Adams 1778. Manufactures, paper, foundry work, fabrics, etc. It has a public library and a town board of three selectmen. Pop. (1900) 11,134.

Adams Family, of Massachusetts. In the varied abilities and conspicuous public importance of its members, this family confessedly outranks every other in the United States. It has furnished in a single line two Presidents, both of great weight and permanent importance, and even more interesting as virile and individual characters, provoking admiration or hate, but never indifference; a statesman and a diplomat of high order; the author of one of the two first-rate histories yet written in America, matter and style both considered; a noted financier and business magnate, and prominent author as well; another keen and vigorous writer; and an able lawyer and local politician who might have attained larger importance but for belonging to a party in a hopeless minority in his State. The founder in America was Henry Adams, an Englishman with eight sons, who removed to Braintree, Mass., in 1636; but the fortunes of the family began when to this tough stock — in the person of John Adams, who died in 1760, a selectman of Braintree and a deacon, and a farmer almost a rich man for the times — was added the energetic, passionate Boylston blood, a strain commemorated in Boylston Street, Boston, and the town of Boylston, Mass. The son of John Adams and Susanna Boylston was President John Adams (q.v.), the real founder of the family greatness and its striking individuality. All its members since have been distinguished by the same general qualities in varying mixture. They have mostly been vehement, proud, pugnacious, and independent, with hot tempers and strong wills; but with high ideals, dramatic devotion to duty, and the intense democratic sentiment so often found united with personal aristocracy of feeling. They have been men of affairs first, with large practical ability, but with a deep strain of the man of letters which in this generation has outshone the other faculties; strong-headed and hard-working students, with powerful memories and fluent gifts of expression. But no curio of heredity in all time is stranger than the contrast between the President father and his President son, John Quincy Adams (q.v.), when it is remembered that to the fiery, combative, bristling Adams-Boylston blood was added an equal strain from the gay, genial, affectionate Abigail Smith (see ADAMS, ABIGAIL). The son, though of deep inner affections, and even hungering for good will if it would

come without his aid, was on the surface incomparably colder, harsher, and thornier than his father, with all the socially repellent traits of the race and none of the softer ones. The father could never control his tongue or his temper, and not always his head: the son never lost the bridle of either, and much of his terrible power in debate came from his ability to make others lose theirs while perfectly keeping his own. The father had plenty of warm friends and allies — at the worst he worked with half a party: the son in the most superb part of his career had no friends, no allies, no party except the group of constituents who kept him in Congress. The father's self-confidence deepened in the son to a solitary and almost contemptuous gladiatorship against the entire government of the country through long years of hate and peril. The father's irritable though generous vanity changed in the son to an icy contempt or white-hot scorn of nearly all about him. The father's spasms of acrimonious judgment steadied in the son to a constant rancor always finding new objects. The country has reason to be thankful for his unamiable traits, for each one strengthened his fibre to do the work awaiting him, and only John Quincy Adams could have accomplished the work of John Quincy Adams. His son, Charles Francis Adams, Sr., had the useful and forcible qualities of both without their besetting defects. He was in youth as hotly pugnacious as his grandfather; he was always as self-centred as his father, and as willing to stand alone amid hate and incessant conflict: but he had far more self-control than the former, and far less bristling repellence and contempt of co-operation than the latter. His diplomacy was cast in a spot where he was too much «boycotted» to make the softer side of much avail: but he roused no useless and costly hatreds, and ranked the peer in effectiveness of any European diplomat. Of his living sons (see CHARLES FRANCIS, 2D; HENRY; BROOKS) it would be invidious to analyze the personal traits. The former, soldier, railroad commissioner, president of the Union Pacific Railroad, and present historical scholar and publicist, has shown the family traits of courage, independence of thought and action, and intellectual energy, to the full, and is still an active public force. The historian was distinguished during his historical professorship as the most original, independent, and stimulating of instructors; and his history displays not only massive research, enormous power of acquisition in the most widely separated fields, and entire freedom from beaten roads and traditional views, but tempered self-control, the moderation of judgment bred by thorough knowledge, and a pervasive atmosphere of gentlemanly irony. The essayist, assailant of the Massachusetts «theocracy,» and student of economic history to saturation, is as eager and passionate as his great-grandfather, and in striking contrast with his brothers in literary style, but none the less a man to reckon with. The late John Quincy 2d would perhaps have filled a larger public field in a less strongly Republican community. It is not likely that this virile stock has lost its energy with the present generation.

This by no means, however, ends the contributions of the Adams stock to our public life. The patriot, Samuel Adams, the father of American liberty, was own cousin to John Adams the President: a more dexterous and politic man, and much abler political manager, but not otherwise cast in as large mold. From different sons or grandsons of the pioneer have descended William Taylor Adams («Oliver Optic»), the well-known juvenile writer; Charles Baker Adams, the naturalist, and Edwin Adams, the actor, the grandfather of the first being the great grandfather of the second; Herbert Baxter Adams, the eminent American historical scholar and educator, and promoter of the higher historical methods in America; Alvin Adams, the founder of the Adams Express Company; William Claflin, the distinguished Massachusetts merchant and governor, whose mother was an Adams; and many other strong but lesser figures in public and private life.

A'damsite, a variety of the mineral muscovite (q.v.).

Adamson, Patrick, Scotch prelate (real name was spelled Constyne, Constean, Conston, Constant, and Constans; later changed to Constantine, then to Adamson): b. Perth, 15 March 1536; d. 19 Feb. 1592. He took his degree at St. Andrews, and in 1566 went to Paris as tutor. Here he wrote a Latin ode on the birth in June of James VI., and called him «king of France and England,» for which the French court gave him six months' imprisonment. Released, he went to Padua, Geneva, and Paris, and finally to Bourges, where he lay in hiding for seven months in fear of the rage against Protestants let loose by the massacre of St. Bartholomew (1572), and which cost his host's life. Recalled to Scotland (in 1573), he became a prominent minister, one of the commissioners to settle Church matters, and chaplain to the regent Morton, who in October 1576 made him archbishop of St. Andrews. The tragedy of his life lay in his attempting to be an old-fashioned prelate in the new Scotland which hated prelacy, and to air High-Church preferences before men who considered them popery. He began the warfare himself by declaring that he would oppose all attempts to deprive the archbishopric of any of its former power; the presbytery took up the glove, and never ceased till they had pulled him down. He was assailed first for not having been consecrated to his post; making his peace somehow for this, they again attacked him for insolence to the presbytery, for opposing its interests in Parliament, for popery, and heresy. The conflict grew so hot that he retired to the castle of St. Andrew's, where he was cured by a «wise woman» of a disease the doctors could not handle, and the presbytery afterward seized and burnt her for it. In 1583 he went to England as James' ambassador, exciting attention by his eloquence, and being savagely libeled by the Presbyterians for alleged looseness of behavior. Returning next May, he was high in favor with James, and his chief agent or prompter in severe measures against the Puritans. In December 1585 he published a paper on the «King's Majesty's Intent in the Late Acts of Parliament,» which was a chief article in his derelictions then, but in 1646, in the heart of the Civil War, was reprinted by the Puritans as on their own side. In 1585 Andrew Melville and other Presbyterian leaders returned after the Raid of Ruthven (q.v.), and that party was gaining the upper

hand: Morton had been executed in 1581. In April 1586 Adamson was impeached and excommunicated; the next year the excommunication was removed, but in 1588 he was freshly accused,— among other things, of mutilating and abstracting registries,— and the king, tired of the quarrel or convinced that it was Adamson's fault, transferred the revenues of his see to another party and left him in actual want for himself and family. A small pension was afterward granted him, but he died poor and wretched.

Adamson, Robert, Scottish philosophical writer: b. 1852; d. 1902. He was professor of philosophy at Owens College, Victoria University, Manchester, England. He wrote 'The Philosophy of Science in the Middle Ages' (1876); 'On the Philosophy of Kant' (1879); 'Fichte' (1881).

Adana, an ancient town in the S.E. of Asia Minor, capital of Adana vilayet, on the Sihun, about 25 m. from its embouchure in the Mediterranean, and about 30 m. from its port Mersina, with which, and with Tarsus about half way between, it is connected by railway. Pop. 45,000.

Adanson, å-dän-sōṅ, **Michel,** French naturalist and traveler (of Scottish extraction): b. 7 April 1727; d. 3 Aug. 1806. Although he gave much time and attention to the study of the sciences, particularly electricity, his chief work was in the realm of botany. From 1784 he spent five years in Senegal and collected a large number of plants and animals which he classified and described. His more important works are: 'Histoire Naturelle du Sénégal' and 'Familles des Plantes,' in which he opposed the system of Linnæus.

Adansonia. See Baobab.

Adaptation, the power and process of gradual change in an organism to fit it to changing conditions of environment. See Biology; Evolution.

The initial causes of life and evolution are motion and change of condition or environment. Whether there is a principle of life or a special impelling life-giving force or not, or whether what we call life is only a mode of being, we can easily perceive and realize that life is a relation, a process, and a process of adaptation or adjustment to the environment both physical and biological. Adaptation is a fundamental fact in the material universe; the different cosmical realms are interrelated in their action, and the harmony existing in the movements of the heavenly bodies have excited the wonder and admiration of mankind from the time when man walking erect could look toward the heavens and perceive the stars and guide his course by them. So also in the beings endowed with life. The adaptation of the living world to the environment is a universal fact. The individual members of each species of plant and animal are perfectly adapted to their surroundings. Though the individual may suffer or perish, in the long run the death of individuals does not disturb the harmony existing throughout nature, which has attracted the attention of observers and naturalists from the earliest times. It should be observed that plants and animals often have structures or habits which are not adaptive, but this is an exception to the rule, and does not interfere with the general course of nature.

By the terms environment, surroundings, conditions of life, medium or *milieu*, or *monde ambiant,* we mean the nature of any region or area on the earth's surface stocked with plants and animals. The nature of the earth's surface, of the soil, of well-watered regions, of deserts, plains, or barrens, the physics of the air and sea, are taught in our text-books of physical geography. Each such area is inhabited by assemblages of living beings adapted to such or such conditions or to such a climate, whether dry or humid, hot or cold. We speak of alpine or arctic life, of the flora and fauna of deserts, of mountains, of lowlands, of the great plains, of forests, of the coasts and abysses of the sea. The word « fauna » means the assemblage of animals inhabiting any area, as the word « flora » is used for the plants. Now each of these areas, with its peculiar surface features, climate, soil, etc., is characterized by a set of plants and animals perfectly adapted to it, and which flourish better there than in adjoining regions.

The most successful groups of animals, considered numerically, are the insects and the birds, which have become adapted for a life in the air, for flying, where they are more or less out of reach of their creeping enemies. Adaptation to this or that mode of life has been the cause of variability. Every species is adapted to its special niche or habitat.

The most remarkable cases of adaptation to extreme conditions of life are seen in animals living in the darkness of caves, or in the dark abysses of the sea, or parasitic animals, as the fluke and tapeworm, the root-barnacles (*Sacculina*), the fish-louse (*Lernæa*), and many insects. In all these forms the body has, as the result of a parasitic life, undergone profound modification, becoming so atrophied in certain respects as to present the utmost contrast to their free-living allies. Adaptation is continually correlated with certain given conditions. If the conditions be changed, in time the organisms, unless they are modified and changed to what we call new species, become inadapted, unfit for the new environment, and unsuccessful in the struggle for existence.

Extinct species are such unfit, inadapted forms. However well adapted they were at the period in which they lived, when the conditions of existence changed: when the climate changed from warm to cold, or the reverse; when the soil changed its elevation above the sea, or degree of dryness or humidity; when one area subsided, and another became elevated,— certain species or groups of species, unless they migrated, or were plastic enough to undergo modification and become what we call « new » species or « new » genera, unable to resist the change, died out,— became extinct. It is the harder parts of these extinct species which we find in the rocks and call « fossils.» They are the relics of former worlds, witnesses of the profound changes in physical geography through which our planet has passed. If we examine these fossil shells, and the remains of the hard parts of insects, the bones of reptiles, birds, mammals, or whatever they are, we perceive no imperfection, no half-formed organs, no signs of decay. We see no reason why they were not in their lifetime as species perfectly adapted to their environment. But living in a changing world, they became

useless, cumbered the ground, and had to succumb in the struggle for existence, and make way for those forms better adapted to the new conditions environing them.

But extinction has not been thoroughgoing and complete. A few ancient primitive forms have persisted and are still flourishing. Such are many of the *Protozoa* (*Saccamina* and others), the *Lingulella* and *Lingula, the* king-crab (*Limulus*), the *Peripatus* and *Scolopendrella*, which are probably the ancestral forms of insects; among the fishes the Australian lung-fish (*Ceratodus*), and among lizards the *Hatteria* of New Zealand. These forms, by reason of their astonishing vitality, have withstood the most widespread and the profoundest geological changes, but they are exceptional forms. On the other hand there were a vast number of species which were plastic enough to yield to the changes in their surroundings and became modified into new species adapted to the new conditions of existence. It is undoubtedly the case, then, that certain forms became inadapted and suffered extinction, though all through the ages the plant and animal census by no means became at any time lessened, but rather gradually increased in extent. Another fact clearly established is that the earlier forms were generalized and the later were specialized, and the former, the ancestors of the present species, had to make way for their more specialized descendants. Thus the trilobites were succeeded by the king-crabs, the creeping dinosaurs were succeeded by the flying reptiles or pterodactyls, and the highly generalized tailed *Amphibia* yielded the right of way to the tailless frogs and toads of the present day. Adaptation, then, is the process of modification of organisms caused by changes in the conditions of life. See also EVOLUTION; SPECIES.

Adar, Jewish month, 12th of the ecclesiastical and 6th of the civil year; representing parts of February and March of ours. The 7th was a fast for the death of Moses, the 9th for the falling-out of Hillel and Shammai. But the important days were the 13th, a fast in commemoration of that of the Jews for their threatened destruction by Haman (see ESTHER), followed by a feast on the next two days for their escape.

Adar'ce, a-där'sē, a salty deposit found on the grasses and sedges growing in wet places in ancient Galatia. It is used somewhat for cleansing the skin in cases of leprosy.

Adda (ancient Addua), a river of north Italy, descending from the Rhætian Alps, falls into Lake Como, and leaving this joins the Po after a course of about 170 miles.

Addams, Jane, American philanthropist: b. Cedarville, Ill., 6 Sept. 1860. Graduated at Rockford College in 1881, after post-graduate studies in Europe and the United States she became an active social reformer. She inaugurated in 1889 at Chicago the establishment known as Hull House, an adaptation of the « social settlement » plan to Chicago conditions. She has acted as street-cleaning inspector in Chicago, and has lectured on the improvement of the condition of the poor in great cities; and for executive power, practical rationality, and unselfishness is one of the leaders of American social reform. See SOCIAL SETTLEMENTS.

Addax, or **Addas** (Lat., of African origin), a North African antelope (*Addax nasomaculatus*), related to the oryx and similar to it in habits. Its large broad hoofs fit it for traveling over loose shifting sand; it has a long tail, long ears, and spirally-twisted horns three to four feet high. The animal measures about three feet in height at the shoulder; in color it is nearly white, with shading of reddish brown on the head and front of the body. The hoofs are black and there is a black, shaggy marking on the forehead above a white blaze on the nose. It is now becoming very rare in all parts of the Sahara. The Arabs hunt the adax with greyhounds.

Adder (Anglo-Saxon *nædder*, Goth. *nadro*, Ger. *natter*, a snake), a colloquial name for several poisonous snakes, mostly belonging to the family *Viperidæ*, such as the copperhead, moccasin, asp, etc.; and also for certain harmless snakes of the family *Colubridæ*, particularly the spreading adder (*Heterodon platyrhinus*), which when angry resembles the poisonous snakes. (See HOGNOSE.) In England the name denotes the only venomous snake of Great Britain,— the European viper (*Pelias berus*). See COPPERHEAD; DEATH-ADDER; PUFF-ADDER; VIPER; etc.

Addicks, John Edward, American capitalist: b. Philadelphia, 21 Nov. 1841; became wealthy and prominent first as a flour merchant, then as a gas manufacturer, organizing and becoming president of the Bay State Gas Co. of Boston in 1884, and buying control of the Brooklyn (N. Y.) Gas Co. in 1892. For eight years (1895–1903) he has been of national prominence as candidate for the United States senatorship from Delaware, which he has not succeeded in obtaining, but till recently he has been able to prevent the election of any rival, leaving first one and since 1901 both of Delaware's two seats vacant. The details are: In 1895 his rival was H. A. Du Pont; among the members of the legislature voting was the former speaker of the Senate, now governor through the death of Gov. Marvel: the Democrats and Populists declared his vote illegal, and refused to seat Du Pont. In 1896 the Republican State Convention to elect delegates to the St. Louis National Convention split and elected two sets, Du Pont and Addicks: the former were recognized as « regular » by the St. Louis Committee on Credentials, and the other section called themselves Union Republicans. In 1899 a successor to Senator Gray was balloted for, but there was no election. In 1900 as in 1896 two sets of delegates went to Philadelphia, and this time the committee seated the Addicks party; though he was thus recognized as State party chief, the 1901 election for senator was again a stalemate, and as there were two to elect, the State was left entirely unrepresented in the Senate. In the session of 1903 Addicks nominally withdrew, and a coalition of the Regular and the Union Republicans elected two Senators, a Regular for the short term and a Union for the long term.

Adding-Machine. See CALCULATING-MACHINE.

Addington, Henry, VISCOUNT SIDMOUTH, English statesman: b. 30 May 1757; d. 15 Feb. 1844; educated at Winchester and Brasenose

College, Oxford; he then studied law, and, through the influence of Pitt, entered Parliament (1784); was speaker of the House of Commons (1789–1801); chancellor of the exchequer and first lord of the treasury; he put through a bill disqualifying clergymen from sitting in the House of Commons, and later, with Pitt's advice, negotiated (1802) the Peace of Amiens, a cessation of war much needed by England. In 1805 he was raised to the peerage. As home secretary (1812–22), he was strict in his administration of justice and in conservative oversight of the press and public meetings. Partly due to his too great zeal was the "Manchester massacre." He resigned in 1824, owing to his disapproving of the recognition of the independence of Buenos Ayres.

Addison, Joseph, English essayist, son of Rev. Lancelot Addison, subsequently dean of Lichfield: b. at his father's rectory, Milston, Wiltshire, 1 May 1672; d. 17 June 1719. At 11 he was sent to the Charterhouse, where he made the acquaintance of his friend and future collaborator Steele. At 15 he proceeded to Oxford, entering first at Queen's College, but two years later being elected to Magdalen College for skill in Latin versification. He took M.A. in 1693, and held a fellowship in his college from 1699 to 1711. He had contemplated entering the clerical profession, but was diverted from his purpose by his literary tastes and by the early patronage he received from some of the greatest statesmen of the Whig party. Addison had the good fortune to secure as his earliest patron the poet Dryden. With sympathetic appreciation of Dryden's skill as a translator of classical poetry, the young scholar addressed to him some complimentary verses, which the poet approved of and inserted in his ‹Miscellanies› in 1693. A translation of the fourth «Georgic,» with the exception of the story of Aristæus, by Addison, appeared in the same collection in 1694, and he subsequently translated for it two and a half books of «Ovid.» A still higher honor was conferred on Addison by Dryden in prefixing his prose essay on Vergil's «Georgics» to his own translation of that poem, which appeared in 1697. Addison published in 1694 «An Account of the Greatest English Poets,» a running criticism in verse, which he dedicated to his fellow-student, the afterward celebrated Dr. Sacheverell. It is said to be chiefly notably for the ignorance, common to the day, which it displays of early English poetry.

Through the introduction, it appears, of Congreve, Addison early secured an able and powerful patron in Charles Montague, afterward Earl of Halifax, and in 1695 his own pen secured a greater in Lord Somers. He dedicated to this nobleman, then lord-keeper, a poem on one of King William's campaigns, and received as his reward a pension of £300 to enable him to travel in order to fit himself for the service of the king. In 1699, in which year appeared a collection of his Latin poems in the second volume of the ‹Musarum Anglicanarum Analecta,› he left England, and after spending more than two years in France and Italy was returning home through Switzerland when he was instructed to repair as envoy to the quarters of Prince Eugene, then engaged in an Italian campaign. The death of King William in March 1702 cancelled this appointment with the overthrow of his friends. He says, indeed, that he never received more than a single year's payment of his pension, and had to defray the expenses of his travels himself. Nevertheless he was able to extend his tour to Germany and Holland, and returned to England at the close of 1703, having attempted without success to procure an appointment as a traveling tutor.

During his residence abroad his pen had not been idle. His tragedy of ‹Cato› is supposed to have been written, subject to after revision, during his stay in France. During his journey across Mount Cenis he wrote his «Letter from Italy,» esteemed the best of his poems, and in Germany his «Dialogues on Medals,» which was not published till after his death. His ‹Remarks on Several Parts of Italy in the Years 1701–03› was published in 1705. It is an impersonal record of impressions in which current events have hardly any place, the absorbing topic being the correspondences traced between passages in the Latin poets and the scenes it illustrates. It was dedicated to Lord Somers. The first ministry of Queen Anne was a coalition one, in which the Whigs had still considerable power, chiefly due to the victories of Marlborough. Godolphin mentioned to Halifax his desire to have the achievements of the great commanders celebrated in appropriate verse. Halifax strongly recommended Addison, and the commission was at once assigned to him, and he produced the «Campaign,» which was about as good as a poem made to order by a man of taste and scholarly accomplishments, who was not quite a poet, could be expected to be. Before it was half finished Godolphin's approval was expressed in the form of an appointment to succeed Locke as a commissioner of appeal on excise. One official appointment succeeded another till the fall of the ministry, whose favor he had now made, in 1710. In 1706 he became under-secretary of state to Sir Charles Hodges, next year he accompanied Lord Halifax as his secretary on a mission to the Elector of Hanover. In 1708 he was elected member of Parliament for Lostwithiel, a seat he exchanged in 1710 for Malmesbury, which place he continued to represent till his death. In 1709 he became secretary to Lord Wharton as lord-lieutenant of Ireland.

It may here be noticed that Addison's temperament, which greatly facilitated his elevation, determined its limit in a political direction. Extremely shy and even awkward in company, especially among persons of any superiority of pretension, he joined with this diffidence extreme caution of offending and solicitous anxiety to oblige. These qualities, which recommended him to men in office, wholly disqualified him for parliamentary life. He is said to have once attempted to speak in the House: but, if ever he had a higher ambition, he sank at once and irretrievably into the position of an absolutely silent member.

The fall of the ministry in August 1710, followed by the accession to power of an uncompromising Tory ministry, happened fortunately for Addison's fame. While he was absent in Ireland his old school companion Steele had started a paper partly devoted to news; but chiefly to essays of a social, moral, and literary character, the *Tatler*. Addison discovered the author

of the enterprise by a literary criticism which he had communicated to his friend, and was readily admitted to share in it. The *Tatler* was begun 12 April 1709, and terminated 2 Jan. 1711. It was followed on 1 March by the *Spectator*, which dropped the news section and consisted entirely of essays. It continued till 8 Dec. 1712. The *Guardian* succeeded, from 2 March to 1 Oct. 1713, and the *Spectator* was resumed from 18 June to 20 Dec. 1714. The *Tatler* was published thrice weekly, on Tuesdays, Thursdays, and Saturdays; the *Spectator* and *Guardian* every week day. The bulk of the papers were contributed in nearly equal proportion by Steele and Addison.

Addison's contributions to the *Spectator* are distinguished by one of the initials C., L., I., O. In humorous and satirical character sketches he hardly excelled, perhaps equalled Steele. If more refined he was less direct and pointed. But he was far ahead of his fellow contributor in scholarship and literary taste, and in the breadth and height of his ambition. He poured forth the stores of his knowledge on a greater variety of subjects, and indulged his imagination in more elaborate and artistic creations. But besides these independent efforts of his own, he aspired to be a judge and censor of the literary productions of others, and he was, perhaps, beyond any man of his day, well qualified for the task. Certainly his judgments had less force and perhaps less depth than Johnson's, but they had much more of breadth, harmony, and completeness, were woven with more art into a system depending on theoretical principles, and were delivered with a grace and eloquence of which the oracular moralist was no master. If his system was somewhat shallow, it had probably the merit of directing attention more to criticism, and preparing the way for better and more philosophic standards of appreciation. Among the most remarkable of his contributions to the *Spectator* are his criticism on Milton's ‹Paradise Lost,› his essays on the ‹Pleasures of the Imagination,› ‹Vision of Mirza,› his Saturday essays on moral and religious themes, and his ‹Reflections on the Divine Perfections.› Pre-eminent among his character sketches is Sir Roger de Coverley. Steele originated the idea of a «Spectator» Club and sketched the characters of its members. That of Sir Roger was immediately appropriated by Addison, to whom the delicate humor of its subsequent development is exclusively due. The remaining works of Addison not yet mentioned are of comparatively little interest or importance. In opposition to the *Examiner*, conducted by Swift, he wrote, in the latter part of 1710, five numbers of a *Whig Examiner*. In 1713 he published, anonymously, «The Trial and Conviction of Count Tariff,» a libel on the financial policy of the ministry. He had assisted Steele at an early period with his comedy of the ‹Tender Husband,› and the drama of ‹The Drummer or the Haunted House› was published by Sir Richard Steele after his death and attributed to him. The *Freeholder*, a political paper in support of the government, published twice weekly from 23 Dec. 1715 to 29 June 1716, was written entirely by him. He also wrote a work on the ‹Evidences of the Christian Religion,› and a ‹Discourse on Ancient and Modern Learning.› ‹Cato› was brought on the stage in April 1713, reluctantly, as is said, and though destitute of dramatic qualities and even deficient in poetry had a great run of success, which was largely owing to political causes.

In August 1716 he married the Countess Dowager of Warwick. This connection brought him little accession of fortune, as the widow forfeited her jointure by her remarriage. Her haughty demeanor, nevertheless, is said to have made his home unbearable to a man of his nicety of feeling. Whether from this cause, or from the long habit of frequenting taverns, to which he appears at first to have had rather an aversion, he acquired, according to prevalent reports, a habit of excessive wine-bibbing which shortened his days. These latter days were distinguished by a return to political life, and darkened by some painful literary quarrels. On the death of Queen Anne the lords justices who assumed the government appointed Addison their secretary. For a brief period he resumed his former office of secretary to the lord-lieutenant, and in 1715 he was named one of the lords of trade. In 1717 the leading Whigs retired from office, leaving an attenuated party called the German ministry. From this ministry, on 16 April, Addison accepted office as one of the principal secretaries of state. He was probably equally unqualified in point of business capacity and of parliamentary efficiency for this responsible post, and he was probably also sensible of his own incapacity, for it is said that in accepting it he yielded to the ambition of his wife.

He retired after 11 months with a salary of £1,500. Of his literary quarrels one of the bitterest was with Pope. The cause of it was the publication by Tickell, Addison's secretary, of a part of a rival translation of the ‹Iliad,› which Pope suspected was Addison's own, and a remark of Addison's that Tickell's translation was more faithful than Pope's. Pope in revenge wrote the savage satire contained in his lines on «Atticus,» which he published after Addison's death in his «Epistle to Dr. Arbuthnot,» and which at the time he printed and distributed among his friends. Addison does not appear to have replied publicly, but in the *Freeholder* he liberally praised Pope's ‹Iliad.› Addison had also a quarrel with Gay, and on this occasion he appears to have been in the wrong, as he sent for Gay some time before his death, apologized for having injured him, and promised amends. But the saddest, as it appears to have been the paltriest, quarrel, was with his ancient comrade Steele. The cause of it was political. Steele attacked a bill for the limitation of the peerage in the *Plebeian*. Addison replied in a pamphlet called the «Old Whig.» Steele answered that Addison was so old a Whig that he had forgotten his principles, and Addison made a contemptuous reply. Addison died of asthma and dropsy at Holland House.

Of his style as a writer so much has been said that nothing remains to say but to quote the dictum of Johnson, «Whoever wishes to attain an English style, familiar but not coarse, and elegant but not ostentatious, must give his days and nights to the volumes of Addison.» Addison had great conversational powers, and his intimates speak in the strongest terms of the enjoyment derived from his society, but it is acknowledged that he was extremely reserved before strangers. There is a story told of his

having sent for his stepson, Lord Warwick, on his deathbed, and addressed him in these terms, "See in what peace a Christian can die." It is alluded to by Tickell, Addison's executor, and is first told circumstantially by Dr. Young, but the truth of the story has been questioned. Addison was buried in Westminster Abbey. He left a daughter born in the year of his death. His works were published by Tickell in four quarto volumes in 1721. An edition, with notes by Bishop Hurd, in six vols. 8vo, was published in 1811. A more complete edition with Bishop Hurd's notes was published and edited by H. G. Bohn (in the well-known series, six vols.). A recent edition (in six vols.) is that of Prof. Greene. There have been two recent editions of the *Spectator* (both in eight vols.) edited respectively by G. A. Aitkin and G. G. Smith. Among 'Lives' may be mentioned that by Lucy Aikin (1843), which drew from Macaulay an admirable essay, and that by Prof. Courthope.

Addison's Disease, a disease associated with disturbance of the functions of the suprarenal glands and characterized by general depression of the functions, anæmia, lowered tone of the circulatory apparatus, irritability of the stomach, and pigmentation of the skin. This last symptom is the most pronounced and was fully described by Addison in 1855. The disease is more common in men and between the twentieth and fortieth years. It is rare in America.

The chief symptoms are (1) pigmentation of the skin; this is a peculiar brownish, yellow to black, almost bronze-like discoloration; (2) gastro-intestinal symptoms, nausea, vomiting, at times marked pain in the abdomen, frequent attacks of diarrhœa; (3) asthenia, the patient is always very tired, and is incapable of carrying on his regular occupation; the heart muscle also suffers very markedly, there being frequent attacks of rapid and feeble pulse with vertigo, and fainting, sometimes fatal. Headache is frequent and anæmia may be present. The disease is usually fatal, but recovery has taken place.

The treatment is symptomatic, with the prolonged use of the suprarenal gland.

Addled Parliament, The, a nickname given to James I.'s second Parliament, of 1614, because it passed no statute and finished no business. It did, however, settle a far more important question than any point of administration: namely, that the Commons were to have the power of the purse thereafter — that is, the rule of the kingdom — unless the Crown crushed them by force. In a word, it proclaimed the revolution, though not consciously. The previous Parliament had been dissolved for not granting supplies until the king had abolished the illegal imposts and regulated the Court of High Commission by statute — that is, given church as well as state into their hands. The elections for 1614 were contested with a passion unknown for generations: the court candidates were overwhelmingly defeated, and 300 of the victorious ones were new men sent up for the first time, among them John Pym, Thomas Wentworth (afterward Earl of Strafford), and John Eliot. After a two months' session they became involved in a quarrel of privilege with the Lords, and the king dissolved the House on that pretext,— really on the point of their refusal of supplies,— and imprisoned four of them.

Add-Ran Christian University, a Waco, Tex., coeducational institution; organized in 1873 under the auspices of the Church of the Disciples. Reported in 1899: Professors and instructors, 20; students, 200; volumes in the library, 5,000; grounds and buildings valued at $150,000; income, $20,000; number of graduates, 200; president, Albert Buxton, Ph.D.

Ade, George, American journalist and author: b. Kentland, Ind., 9 Feb. 1866. He made his first mark as a writer for years of "Stories of the Streets and the Town" in the Chicago *News*, with remarkable variety of motive and local-reporter's knowledge; published 'Artie,' made up from these, and in 1897 the dialect story 'Pink Marsh'; in 1901-2 two sets of 'Fables in Slang,' full of pungent wit and knowledge of the less agreeable phases of human character; and in 1903 the satirical comic opera, 'The Sultan of Sulu,' a musical comedy, 'Peggy from Paris,' a political comedy, 'The County Chairman,' a comedy of college life, 'The College Widow,' and others.

Adee, Alvey A., American diplomat: b. Astoria, N. Y., 27 Nov. 1842, son of a fleet surgeon; was secretary of legation at Madrid 1870-7, *chargé d'affaires* at different times; in 1878 became chief of the United States diplomatic bureau, 1882 third assistant secretary of state, 1886 second assistant, which he still remains. He was secretary of state *ad interim* 17-29 Sept. 1898; and acting secretary during some of the most acute Chinese troubles of 1900.

Adelaide, capital of S. Australia, 7 m. by rail S.E. of Port Adelaide, on St. Vincent Gulf. It stands on a large plain, and is walled in on the eastern and southern sides by the Mount Lofty range; the town proper is enclosed by a wide belt of garden shrubbery. The first settlement was made in 1836, and named after the queen of William IV. The Torrens divides the town into North and South Adelaide, the former being occupied chiefly with residences, and the latter forming the business portion of the town. Four substantial iron bridges span the Torrens, which has been formed by a dam into a lake one and a half miles long. The streets are broad and regularly laid out, especially in Adelaide proper, to the south of the river, where they cross each other at right angles, and are planted with trees. Among the public buildings are the new Parliament Houses, erected at a cost of about $500,000; government offices, post-office, and town-hall; South Australian Institute, with museum, library, and art galleries; and hospital. The botanical garden, with the botanical garden park, covers more than 120 acres of ground. The chief manufactures are woolen, leather, iron, and earthenware goods; but the chief importance of Adelaide depends on its being the great emporium for South Australia. Wool, wine, wheat, flour, and copper ore are the staple articles of export. Among educational institutions the most important are the Adelaide University; St. Peter's (Episcopal) College; St. Barnabas Theological College, opened in 1881, and Prince Alfred (Wesleyan) College. It is the seat of an Anglican and of a Roman Catholic bishop. Glenelg, on the sea, 5 miles away, is a favorite watering-place. Pop. with suburbs (1901) 160,691.

PORT ADELAIDE, its haven, dates from 1840. It is a principal port of call for vessels arriving

from Europe; has railway communication with Melbourne, Sydney, and Brisbane. Tramways were introduced in 1878. Pop. with Semaphore about 15,000.

Adelard, or **Æthelhard,** of BATH, English philosopher and mathematician of the 12th century. Little is known of the facts of his life, except that he traveled widely, visiting Greece, Asia Minor, and Africa. He wrote 'Perdifficilis Quæstiones Naturales' and 'De Eodem et Diverso,' a philosophical allegory in which he sought to reconcile the theories of Plato and Aristotle. He also made a Latin translation of Euclid and of several Arabian mathematical treatises. See ARITHMETIC, HISTORY OF.

Adelbert College. See WESTERN RESERVE UNIVERSITY.

Ad'elieland', an Antarctic continent discovered 20 Jan. 1840 by Du Mont d'Urville. It consists of a chain of mountains without prominent peaks, with a few shallow bays filled with icebergs, and a number of islands with rounded summits.

Adelochorda, a group standing at the base of the branch of phylum *Chordata,* and including certain animals, formerly supposed to be worms, but now placed in the same group as the vertebrates. The class *Adelochorda* is represented by *Balanoglossus,* while with it are provisionally associated two forms of doubtful position, the worm-like *Rhabdopleura* and *Cephalodiscus.* The *Adelocephala* are worm-like, but from the fact that the body is in part supported by a structure supposed to be homologous with the notochord of true vertebrates, and that the animal breathes through gill-slits, like those of the lowest vertebrates, it is supposed to be related to some extinct form which gave rise to the vertebrates. It is also itself probably an ancestral persistent form. If we throw out the doubtful forms *Rhabdopleura* and *Cephalodiscus,* leaving only *Balanoglossus,* we have the old group *Enteropneusta.* A typical example of the *Adelochorda* is *Balanoglossus* (q.v.).

Adelphi College, Brooklyn, N. Y., a coeducational, non-sectarian institution, was incorporated by the regents of the University of the State of New York, 24 June 1896. It is intended to be a school of arts, a college of liberal culture. The requirements for admission and graduation are the same as those of the leading Eastern colleges. It is the only institution in Brooklyn in which a woman may obtain the usual baccalaureate degrees. The curriculum is arranged semestrally, and eight semesters are required for graduation. The courses in pedagogy are arranged so that the studies preparatory to the profession of teaching may all be taken as a part of the work offered for the degrees of bachelor of arts and bachelor of science. From the beginning the college has always offered special facilities to students who wish to enter the profession of teaching. It also makes provision in afternoon, evening, and Saturday morning classes for teachers in public schools who desire to study for a degree without giving up their positions. Connected with the college are the Normal School for Kindergartners, with a two years' course, organized in 1893, and School of Fine Arts. The college reported in 1905: professors and instructors, 26; students, 500; volumes in the library, 9,000. Adelphi College maintains a preparatory department, known as Adelphi Academy, which has 50 instructors and 760 students. The total value of the property and endowments of the college is $600,000. The total annual income is $118,000.

Aden, Arabia: peninsula and town belonging to Great Britain, on the S.W. coast, 105 m. E. of the strait of Bab-el-Mandeb, the entrance to the Red Sea. The peninsula is a mass of volcanic rocks, 5 miles long from E. to W., and rising to 1,776 feet. It is joined to the mainland by a narrow, level, and sandy isthmus. The town is on the eastern shore of the peninsula, stands in the crater of an extinct volcano, and is surrounded by barren, cinder-like rocks. The main crater is known as the Devil's Punch-bowl. Frequently the heat is intense; but the climate is unusually healthy for the tropics.

The Romans occupied it in the 1st century A.D. Till the discovery of the Cape route to India (1498) it was the chief mart of Asiatic produce for the Western nations; but in 1838 it had sunk to be a village of 600 inhabitants. The increasing importance of the Red Sea route gave Aden great value as a station for the British to hold; and in 1839 after a few hours' contest it fell into their hands. It is of high importance both in a mercantile and naval point of view, especially as a great coaling station; it has a garrison and strong fortifications.

The population and resources of the place have rapidly increased since 1838, and the opening of the Suez Canal in 1869 gave it a great impetus. The value of its imports (1892–3) was over $20,000,000, while that of its exports (coffee, gums, spices) amounted to over $15,000,000. It is a telegraphic station on the cable between Suez and Bombay, and on the line to Zanzibar and the Cape. To provide for its growing population, a considerable territory on the mainland has been acquired and added to the peninsula, the total area (including the island of Perim) being 75 square miles; and the settlement, which is politically connected with Bombay (7 days' sailing, or 1,819 nautical miles, distant), has a population of over 41,000.

Adhesion, in physics, the force which holds together two surfaces brought in contact; distinguished from cohesion, the mutual attraction exerted by particles of the same body, and from affinity, since the particles adhering remain unchanged. It is a force exerted on each other by the molecules of the adhering bodies, and not to be confounded with mere mechanical contact due to pressure. The wetting of solid bodies is an instance.

It usually happens that when a solid and a liquid come in contact, a film of the liquid adheres to the solid too firmly to be detached, showing its adhesion to the solid to be stronger than the cohesion of its particles or the force of gravitation, as it can be removed only by forcible rubbing or evaporation. On the other hand, solutions are supposably cases where the adhesive force of solid and liquid overbalances the cohesive force of the solid, so that it loses its form and adheres particle by particle; but see SOLUTIONS, the true theory of which is keenly debated. The force of adhesion is measured by poising a metal plate on a balance, and then finding what additional

force is required to detach it from the surface of a liquid which does not wet it (otherwise it would be measuring the cohesive force of the liquid) nor act on it chemically. The phenomena of capillary attraction (q.v.) depend on adhesion. Solid bodies also adhere to solids: most smooth surfaces will adhere; the smoother the tighter; and two plates of polished glass laid together can hardly be parted without breaking them. If the solids are pressed together, it usually increases the adhesive force; but it depends but little on atmospheric pressure. Friction is a looser kind of adhesion, which prevents surfaces moving freely on each other, and may result from gravitation or mechanical appliances. Plating, gilding, etc., also depend on adhesion. Soldering, the use of mortar, cementing, gluing, etc., are familiar applications of the principle, intermediary substances being employed, whose particles have at once great cohesion among themselves and great adhesion to each of the bodies to be joined. A familiar example is the splitting a thin sheet of paper by pasting it between two sheets of cloth and pulling them apart after it has dried: the adhesion of paste to paper and cloth is so great that the paper fibres yield to it. Furthermore, air and other gases adhere to solids: a favorite children's experiment is to float a dry needle in a basin of water, it resting on a cushion of air; and when thermometers are filled with mercury it has to be boiled in them to expel the air that adheres to the glass. Every material body, and every particle of such body in however fine division, is surrounded by its own atmosphere of condensed gases, which are an efficient factor in many physical and chemical phenomena; this property in comminuted bodies is called adsorption, and in metallic substances is sometimes so avid that they grow red-hot.

Adiaba'tic Transformation. In thermodynamics (q.v.) a body is said to undergo an adiabatic transformation when its state or condition is modified in such a way that the following two conditions are fulfilled: (1) There is no exchange of heat between the body and its surroundings; (2) the transformation is reversible at every stage. It is usual to define the adiabatic transformation by stating the first of these conditions only; but the second is equally essential, because if it is omitted the definition will also include the transformation known as "free expansion." (See GASES, GENERAL PROPERTIES OF.) When the body under consideration is a «perfect gas,» and all possible states are excluded from consideration except such as are uniquely determined when the pressure and volume of the body are given, the adiabatic transformation requires that the product pv^k shall remain constant throughout the transformation, k being the ratio that the specific heat of the gas at constant pressure bears to its specific heat at constant volume. For air, k is about 1.41. When the changes that the body can undergo are represented graphically, as for example on a diagram in which the volume is taken as abscissa and the pressure as ordinate, the lines along which the foregoing algebraic expression is constant are called adiabatic lines or curves. Adiabatic transformations are often called isentropic transformations, from the fact that the entropy (q.v.) of the body remains constant along every such line. (For further information concerning lines used in thermodynamics, see LINE.)

Adiaphorists, ä-di-af'or-ists, or **Adiaphorites,** a party or wing of the Lutheran reformers of Germany, who held that certain things practised by the Roman Catholic Church were indifferent and might be received. In 1548 an ecclesiastical controversy broke out among the reformers. The Emperor Charles V. having issued a paper popularly called the «Interim,» in which he prescribed what faith and practice the Protestants were to adopt till the Council of Trent should dictate a permanent form of belief and worship, Maurice, Elector of Saxony, urged Melanchthon and his friends to decide what portions of the document they would accept and follow. Melanchthon considered that to a very large extent the «Interim» might be accepted and obeyed. A controversy in consequence arose between the followers of Luther and those of Melanchthon. It was called the adiaphoristic controversy, and embraced two questions: (1) What things were indifferent; and (2) whether, with regard to things indifferent, the emperor could or could not in conscience be obeyed.

Adi-Buddha, ȧ-de-bud-hȧ, from the Sanskrit, the Primord Buddha, a conception of Buddha due probably to the influence of Christianity. It came into vogue among the Northern Buddhists about the middle of the 10th century. In this conception he is represented as self-existent and omniscient.

Adige, ä'dē-je, a considerable river of N. Italy, which has its source in the Alps of Tyrol, above Brixen; it enters Italy by Bolzano and the valley of Trento, flows in a southern direction by Roveredo, parallel to and for the most part about 6 miles from the lake of Garda, then, turning abruptly toward the east, passes through Verona and Legnano; it afterward enters the great delta between the Brenta and the Po, and, forming several branches, empties its waters into the Adriatic Sea. It is a deep and rapid stream, dividing by its course the old Venetian territories from Lombardy proper. The valley of the Adige has been rendered forever memorable by the wars of Bonaparte.

Adi-Granth, the Bible of the Sikhs (q.v.), mainly compiled by the *guru* (spiritual guide) Arjun (1584–1606), fifth successor of the founder Nanak (q.v.). He gathered up the poetical pieces of his four predecessors, and fragments from other great teachers like Ramananda, Kabir, Namdev, etc., and added compositions of his own. The tenth and last Sikh guru, Govind (1675–1708), made additions to it, and composed an entirely new Granth, the «Granth of the Tenth Reign.» The language of these is an archaic Punjabi called Gurmukhi («from the guru's mouth»). These Granths, with the biographies of gurus and saints, and instructions for ritual and discipline, comprise the Sikh sacred books.

Ad'inole, a variety of the mineral albite.

Ad'ipate, any salt of adipic acid (q.v). Thus the compound of adipic acid with sodium is called sodium adipate.

Adip'ic Acid, an organic acid having the formula $C_6H_{10}O_4$, and crystallizing in monoclinic liminæ which are sparingly soluble in cold

water, but freely so in alcohol and ether. It melts at 300° F. and is formed by the action of nitric acid on natural fats.

Ad'ipite, a gelatinous mineral substance of the same composition as chabazite (q.v.).

Adipocere, ad'i-pō-sēr' Lat. *adeps*, fat, + *cera*, wax), a fatty substance consisting largely of palmitic, stearic, and margaric acids, combined to some extent with ammonia. It is sometimes formed by the decomposition of animal matter from which air has been excluded. It was first observed by Fourcroy. The most notable example of its occurrence was in the Cimetière des Innocens at Paris. A large number of coffins had been piled together in this cemetery for many years, and in 1786–87, when the coffins were removed, it was found that in many cases the corpses had been changed into shapeless masses of a dingy white color and waxy consistency, only the bones remaining unaltered. Adipocere is not a result of the decomposition of albuminous tissue, but is formed from the fats that are present in the body at the time of death, the fatty matter collecting together, undergoing further decomposition, and finally losing its glycerine and oleic acid. A similar substance, called bog-butter, is occasionally found in peat bogs in Ireland and Wales. Sometimes spelled *adipocire*.

Adipo'cerite, a mineral better known as hatchettite (q.v.).

Adipose Tissue, a fatty membrane or tissue. See FAT TISSUE.

Adiposis Dolorosa, a disease described by Dr. F. X. Dercum of Philadelphia in 1892, and characterized by enormous collections of fat in different parts of the body, not in the hands or feet, and associated with neuralgic-like pains and prickling sensations.

Its cause is unknown. The internal use of the thyroid gland has been of benefit in some cases.

Adirondack Mountains, a group in the N.E. part of New York State, lying between the depressions occupied by Lake Champlain on the E., the St. Lawrence on the N.W., and the Mohawk River on the S. The group is sometimes included in the Appalachian system, but physically and geologically the two uplifts are quite independent. The Adirondacks cover an area of more than 12,000 square miles and include within their limits most of the counties of Clinton, Franklin, Essex, and Hamilton, and portions of St. Lawrence, Lewis, Herkimer, and Warren. They are formed by several folds arranged parallel or *en echelon*, with a northeast-southwest trend, sloping on either side toward the narrow longitudinal valleys that separate the individual ridges. Most of the peaks have a rounded outline due to long-continued erosion, although in the northern part, where the highest elevations are found, the peaks are bold and picturesque and have bare rock walls rising several hundred feet in vertical escarpments. The summit of the group is Mt. Marcy, 5,344 feet above the sea, and there are many prominences exceeding 4,500 feet, including Mt. McIntyre, 5,112; Skylight, 4,920; Whiteface, 4,872; Santanoni, 4,644; and Nipple Top, 4,684 feet. Toward the south and west the elevations become less pronounced and rise but a few hundred feet above the level of the plateau, which stands 1,500 feet or more above the sea. The parallel ranges are interrupted frequently by gaps or passes; some of them, like the Avalanche Pass and Indian Pass, possessing beautiful scenic features. Gorges and waterfalls occur along many of the stream valleys, the Ausable Chasm being especially noteworthy.

Rivers and Lakes.— The Adirondacks form the water parting between the Hudson and St. Lawrence, both of which streams receive many important tributaries from this region. Most of the western region drains directly into the St. Lawrence through the Oswegatchie, Grass, Raquette, and St. Regis rivers, but a small portion is drained by the Black River, which flows into Lake Ontario. On the eastern side there are the Saranac and Ausable rivers and many short streams flowing into Lake Champlain. The Hudson River receives the waters of the Sacondaga, Indian, and Boreas, and has its source in the interior of the mountains in the northeastern part of Hamilton county.

The lakes are perhaps the most attractive feature of the Adirondacks; they are distributed over the entire area to the number of many hundreds. The greater proportion lie in the larger valleys, to which they conform more or less closely in outline, being elongated along a northeast-southwest axis. Many, however, are nestled on the higher slopes at an elevation of 2,500 feet or more above the sea. Lake Tear of the Clouds on the crest of Mt. Marcy has an altitude of 4,320 feet. Lakes Champlain and George, the largest of the Adirondack lakes, are among the most attractive sheets of water in the United States. Among the smaller lakes much frequented by tourists are Long, Raquette, and Blue Mountain in Hamilton County, the Fulton Chain in Hamilton and Herkimer counties, St. Regis and the Saranacs in Franklin County, and Lake Placid in Essex County. Most of the lakes are of glacial formation, the outlets of the old rivers having been obstructed by deposits of glacial material.

Geology and Mineral Resources.—The strata of which the mountains are formed belong to the most ancient geological period, consisting for the most part of crystalline formations which were uplifted long before the Appalachian ranges had been defined. Gneisses, granites, and basic igneous rocks predominate, although there are small areas underlaid by limestones and quartzites. One of the most prominent types is a basic feldspar rock called anorthosite, composed almost entirely of the mineral labradorite. It constitutes the highest peaks in Essex County. On the borders these ancient formations are overlaid by early Palæozoic strata of Cambrian and Silurian age, which have been little disturbed from their original horizontal position. The whole region was invaded by the great northern ice-sheet, which eroded and polished the rock surfaces and upon its retreat left a heavy mantle of drift covering all but the highest elevations. Valuable ores and minerals occur at numerous localities. The deposits of iron ores have been of great economic importance, although in recent years the industry has suffered from competition with the Lake Superior and Pennsylvania ores, which can be extracted at much less expense. The mines of

magnetite ore near Port Henry yield a large annual output, which is shipped to distant points for smelting. There are also deposits at Lyon Mountain, Lake Sanford, and Benson Mines, and other localities, which are not exploited at present. One of the richest graphite mines in the United States is located at Hague on Lake George. Garnet for abrasive purposes is mined in large quantities at North River, while extensive deposits of foliated talc occur near Gouverneur. Marble, granite, and other stones suitable for building and other purposes, are the basis of a large quarry industry.

Forests.— Pine, spruce, and hard woods are found over extensive areas. The mountains have been denuded of much of the larger timber, and the principal lumbering industry is based upon the cutting of pulp-wood for paper manufacture. Spruce and poplar are most valuable for this purpose. The wholesale destruction of the forests has induced the State government to purchase extensive tracts with a view to forest-cultivation and to preserve the sources of the principal rivers. (See ADIRONDACK PARK.)

Game.— The Adirondacks are one of the favorite hunting-grounds of America. Owing to the stringent legal restrictions limiting the season for killing game, there is an abundance of deer, rabbits, partridge (grouse), and waterfowl. Deer are hunted chiefly by stalking, the use of dogs being prohibited. Black bear and wildcats may be found in many parts of the mountains, but moose and caribou, which formerly were plentiful, have entirely disappeared. Several moose were introduced from other States in 1902 with the hope that they might again roam through the woods in numbers. Brook and lake trout and black bass are found in most of the streams and lakes and furnish excellent sport for the angler.

Resorts.— The climate of the mountains is bracing and healthful; in the summer season the heat is tempered by cool mountain breezes and by the elevation, and the severe cold of winter is made more endurable by the dry atmosphere. There are many sanitariums for invalids, especially for those afflicted with pulmonary diseases. The pleasure-seekers, who visit the mountains in great numbers, find ample accommodations in the many hotels and camps. The railway lines afford easy access to most parts of the Adirondacks, while by taking advantage of the network of rivers and lakes the most remote regions can be reached without much difficulty. During the summer months steamboats make regular trips for the convenience of travelers on many of the larger lakes. See NEW YORK (STATE).

Adirondack Park, a large district, principally forest land, set apart by the State of New York in 1892 for the protection of the watershed of the Hudson and other rivers of the State, for public recreation, and for the practical study of forestry. (See CORNELL UNIVERSITY.) It covers Hamilton County, and parts of Essex, Franklin, Herkimer, and St. Lawrence counties, and contains many mountains and lakes. From time to time additions are made to the reservations, as the appropriations are available, and it is hoped that in time the whole region not under cultivation for crops, will be under State control, and while saved for the use of the people, will become a source of revenue to the State from the forestry industries.

Adit («approach»), an underground passage with but one opening; distinguished from the tunnel proper, which has two. In military use, the burrow by which miners approach a place they wish to sap. In industrial mining, a gently sloping drift, used to drain a mine of the water coming into the workings from the top or sides, or pumped up from below; usually but improperly called a tunnel. When there are two adits at different levels, the lower one is termed the «deep adit.» The greatest in the United States is the Sutro Tunnel, 2,000 feet deep and 20,000 feet long, made in the palmy days of the Comstock Lode near Virginia City, Nev., to drain the mines along it.

Aditi, ad'ē-tī, in the mythology of the Hindu Rig-Vedas, Infinity endued with life and form, from which are born the Adityas — the source and substratum of the universe; in later Vedic literature, the mother of the gods of storms (which are represented as life-producing), and of the sun. Aditi is the daughter of Daksha and wife of Kasyapa, and besides being the mother of the 33 gods and of the sun, was also the mother of the Tushitas, or the 12 Adityas. The latter in the Vedic literature numbered seven and are the gods of the heavenly light, with Varuna at their head. In the Brahmanas and later they numbered 12, with supposed reference to the months of the year.

Adive, a local Asiatic name of the corsac (q.v.).

Adjective. See GRAMMAR.

Adjustment, in insurance, is the determining the amount of a loss. No specific form is necessary to an adjustment. It must be intended and understood by the parties to a policy to be absolute and final, in order to render it binding. It may be made by indorsement on the policy, by payment of the loss, or by the acceptance of an abandonment. (4 Burr. 1966; 1 Camp. 134; 22 Pick. (Mass.) 191.) If an adjustment is brought about by the fraudulent conduct of one of the parties, it will not bind the other person. (2 Johns. Cas. 233; 3 Camp. 319.) If one party is led into a material mistake of fact by fault of the other, the adjustment will not bind him. (2 Johns. (N. Y.) 157; 2 Johns. Cas. 233.)

Adjutant («assistant»), in the armies of most civilized powers, a staff officer, the chief assistant to the commander of a regiment, battalion, or squadron, in the drill and discipline of the troops, and their general management off the battlefield, and in such other duties as fall to the commander's charge. In the United States army he is appointed by the colonel for four years, has the rank of captain, and is not eligible to reappointment; he is the colonel's secretary, and is generally so indispensable that in time of war ambitious men often dreaded the appointment, as death to further promotion. The squadron and battalion adjutants rank as lieutenants, are similarly appointed for two years, and have the same relation to their chiefs; there are also post, garrison, and brigade adjutants. For further details see the ‹U. S. Army Register.›

Adjutant, a large stork (*Leptoptilus argala*) found in India and southeastern Asia, and so called by the English on account of its erect, officer-like appearance. Its Hindu name is «argala.» Its height is about 5 feet, its spread of wings about 14 feet. The back and wings are slate-colored, the bare, flesh-colored head and neck are marked with black, and elsewhere it is white. The beautiful «maribou» feathers of commerce are taken from the under side of the wings. A pouch, which probably serves some purpose in connection with the organs of breathing, hangs from the under part of the neck and is capable of great distension. The bill is of great size, and the appetite of the bird is correspondingly large. It is a scavenger, its food being carrion, offal, and small live animals, and it runs freely about Indian villages, protected for its useful works. The marabou (q.v.) of Africa is a closely related species.

Adjutant-General, an officer on the staff of the commander-in-chief, his secretary and principal assistant in issuing orders and supervising their execution, making reports and keeping registers, etc.; and having general charge of the drill and discipline of an army. In the United States he ranks as major-general and is a leading officer in the War Department; he has charge of the recruiting service, collection of military information, and preparing annual militia returns. Most of the States have an adjutant-general, similarly related to their militia.

Adler, Cyrus, äd'ler, librarian and archæologist: b. Van Buren, Ark., 13 Sept. 1863. He was graduated at the University of Pennsylvania in 1883, and took the degree of Ph.D. in 1887 at Johns Hopkins, where for several years he was instructor in Semitic languages. Since 1892 he has been librarian of the Smithsonian Institution; special commissioner of World's Fair to Turkey, Egypt, Tunis, Algiers, and Morocco; President of the American Jewish Historical Society, and member of numerous learned societies. He is the author of numerous articles on Oriental archæology, Assyriology, Semitic philology, comparative religion, and bibliography; and one of the editors of the ‹Jewish Encyclopædia.›

Adler, Felix, American lecturer and scholar: b. Alzey, Germany, 13 Aug. 1851, son of an eminent Jewish rabbi. In 1857 he emigrated to the United States, in which country and at Berlin and Heidelberg he was educated. After being for some time professor of Hebrew and Oriental literature at Cornell he founded in New York (1876) the Society for Ethical Culture, of which he is lecturer. Similar societies have been established elsewhere in the United States and in other countries. He is an effective writer and speaker. He has published 'Creed and Deed' (1878); 'The Moral Instruction of Children' (1892). In June 1902 he was called to the newly created professorship of social and political ethics in the department of philosophy in Columbia University.

Adler, George J., German-American philologist: b. Germany, 1821; d. 1868. He came to New York 1833; graduated at the University of the City of New York 1844, and from 1846–54 was professor of German there. He published a valuable 'German-English Dictionary' (1848, many editions since), still very useful for its careful discrimination of synonyms; ‹German Grammar› (N. Y. 1868); ‹Wilhelm von Humboldt's Linguistic Studies› (N. Y. 1868), and translated Fauriel's ‹History of Provençal Poetry.›

Adler, Hermann, Anglo-Jewish leader: b. in Hanover, 29 May 1839. He has lived most of his life in England, where he has held many positions of high trust connected with his race, having been since 1891 chief rabbi of the British Empire, and has been active in general benevolence. He was principal of the Jews' College, London, 1863–91, and as chief rabbi became its president. Besides sermons, lectures, etc., he has written ‹The Jews in England›; ‹The Chief Rabbis of England›; ‹Ibn Gabirol, the Poet Philosopher,› etc.

Adler, Nathan Marcus, German-Jewish leader: b. Hanover, 1803; d. 1890. Educated at Göttingen, Erlangen, and Würzburg, he became chief rabbi of Oldenburg 1830, of Hanover and the provinces 1831; and of the British Empire 1845. He was a chief organizer of schools for Jews in England, assisted Sir Moses Montefiore in raising the £20,000 fund for Palestine, was co-founder of the United Synagogue (association of the leading synagogues), and founder and first president of the Jews' College. He published several volumes of sermons and a commentary on the Targum.

Administration, in law, the management of the personal estate of anyone dying intestate or without an executor. If the deceased leaves real estate, the estate devolves upon heirs related by blood; if personal property is left and no executors named, administrators are appointed by some court.

In the United States a surrogate or judge of probate appoints the administrator, and grants letters of administration. The administrator is a trustee within the jurisdiction of a court of equity as well as of a court of probate. His duties are to inventory the estate, collect accounts due, pay all debts, and distribute the remainder among those entitled to it. In England the power of such appointment was vested in the ecclesiastical courts until 1857, when it was transferred to a court of probate. The personal property of a decedent is appropriated to the payment of his debts so far as required, and until exhausted must first be resorted to by creditors; but by certain statutes, courts may grant an administrator power to sell, lease, or mortgage real estate when the personal estate of the deceased is not sufficient to pay his debts. At common law the real estate of an intestate goes to his heirs; the personal to his administrator. The fundamental rule is that all just debts shall be paid before any further disposition of the property.

Ancillary Administration.— That which is subordinate to the principal administration, for collecting the assets of foreigners. It is taken out in the country where the assets are locally situate.

Of Estates.— The term is applied broadly to denote the management of an estate by an executor, and also the management of the estates of minors, lunatics, etc., in those cases where trustees have been appointed by authority of law to take charge of such estates in place of the legal owners.

Foreign Administration.— That which is exercised by virtue of authority properly conferred by a foreign power. In England and in the United States the general rule is that letters granted abroad give no authority to sue or to be sued in another jurisdiction, though they may be ground for new probate authority. Consequently, when persons are domiciled and die in one country, as A, and have personal property in another, as B, the authority must be had in B, but exercised according to the laws of A. (Story Confl. Laws, 23, 447.) There is no legal priority between administrators in different States. The principal administrator is to act in the intestate's domicile, and the ancillary is to collect claims and pay debts in the foreign jurisdiction and pay over the surplus to his principal. (2 Metc. (Mass.) 114; 3 Day, 74.) But some courts hold that the probate of a will in a foreign State, if duly authenticated, dispenses with the necessity of taking out new letters in their State. So it has been held that possession of property may be taken in a foreign State, but a suit cannot be brought without taking out letters in that State.

Public Administration.— That which the public administrator performs. This happens in many of the States by statute in those cases where persons die intestate, without leaving anyone who is entitled to apply for letters of administration.

Jurisdiction over administrations is in England lodged in the ecclesiastical courts, and these courts delegate the power of administering by letters of administration. In the United States administration is a subject charged upon courts of civil jurisdiction. A perplexing multiplicity of statutes defines the powers of such courts in the various States of the Union. The public officer authorized to delegate the trust is called surrogate, judge of probate, registrar of wills, etc. As to surrogate courts and proceedings therein in the State of New York, see the Code of Civil Procedure (Chase's ed. 1902, ch. 18). The death of the intestate must have taken place or the court will have no jurisdiction. A decree of the court is *prima facie* evidence of his death and puts the burden of disproof upon the party pleading in abatement. 26 Barb. 383. The formalities and requisites in regard to valid appointments, and rules as to notice, defective proceedings, etc., are different in the various States.

In Politics, the word is applied to the collective body of governmental officers exercising authority as an executive power; in this sense being the equivalent of the term government; as, the bill was an Administration (or government) measure. It is also applied to a political term of office; as, during the Roosevelt administration.

Admirable Crichton, crē'ton, (N. Irish Crī'ton). See CRICHTON, JAMES.

Admiral (Arabic *amīr-al* or *emir-al*, « commander of the »— whatever follows it), the highest rank of naval officer. The first English admiral was William de Leybourne (1286). His duties corresponded to those afterward vested in the lord high admiral; viz., the administrative powers now delegated to the lords commissioners of the admiralty. In Great Britain there were formerly three grades of admirals, commanding subdivisions known as the red, the white, and the blue, from the colors of their flags; but this distinction is now abolished. The last lord high admiral was the Duke of Clarence, afterward William IV. In the British navy admirals are classified as admirals, vice-admirals, and rear-admirals, ranking respectively with generals, lieutenant-generals, and major-generals. These distinctions were adopted in the United States navy during the Civil War; the rank of rear-admiral being established in 1862, vice-admiral in 1864, and admiral in 1866, all created for Farragut. David D. Porter succeeded in the titles of vice-admiral and admiral, both of which grades were abolished at his death (1891). In 1899 the title was recreated in the United States navy, and conferred upon George Dewey. In 1882 Congress reduced the number of rear-admirals from 10 to 6, and in 1899 increased it to 18, comprising two classes of 9 each: the first corresponding in rank to major-generals in the army, and the second to brigadier-generals. See NAVY OF THE UNITED STATES.

Admiral. (1) In entomology, a nymphalid butterfly,— any one of several species, as the red admiral (*Pyrameis atalanta*), and the white admirals of the genus *Basilarchia*. (2) In conchology, one of the cones (*Conus ammiralis*). See CONE-SHELL.

Admiralty Inlet, a narrow body of water connecting Puget Sound with the Strait of Juan de Fuca.

Admiralty Island, a mountainous island, 90 m. long, off the W. coast of Alaska, to the N.E. of Sitka; belongs to the United States.

Admiralty Islands, a group of 40 islands, to the N.E. of New Guinea; Basco, the largest of them, being 60 m. in length, mountainous, but fruitful. The total area of the islands is 878 square miles. They were discovered by Schouten in 1616. Carteret named them in 1767. Some are volcanic; others are coral islands. They abound in cocoanut-trees and are inhabited by a race of tawny, frizzle-headed savages of the Papuan stock, about 800 in number. Together with New Britain and some adjoining groups they were annexed by Germany in 1885, and now form part of the Bismarck Archipelago.

Admiralty Law, the system of jurisprudence administered by admiralty courts.

In American law, a tribunal exercising jurisdiction over all maritime torts, contracts, injuries, or offenses. Its civil jurisdiction extends to cases of salvage, bonds of bottomry or hypothecation of ship and cargo, seamen's wages, seizures under the laws of impost, navigation, or trade, cases of prize or ransom, charter-parties, contracts of affreightment between different States or foreign ports, contracts for conveyance of passengers, contracts with material-men, jettisons, maritime contributions, and averages, and generally to all assaults and batteries, damages, and trespasses, taking place on the high seas. Its criminal jurisdiction extends to all crimes and offenses committed on the high seas or beyond the jurisdiction of any country. A suit is commenced in admiralty by filing a libel, upon which a warrant is issued for the arrest of the person, or attachment of his property if he cannot be found, or a simple monition to appear; or, in a proceeding *in rem*, a warrant is issued for the arrest of the thing in question.

Admission. *In practice,* the act by which attorneys and counsellors become recognized as officers of the court and are allowed to practise.

In corporations or companies, the act of a corporation or company by which an individual acquires the right of a member of such corporation or company. In trading and joint-stock companies no vote of admission is requisite, for any person who owns stock therein, either by original subscription or conveyance, is in general entitled to, and cannot be refused, the rights and privileges of a member. Nothing more can be required of a person demanding a transfer on the books than that he prove to the corporation his right to the stock.

In evidence, a concession or voluntary acknowledgment made by a party of the existence of certain things or conditions, or of the truth of certain statements. The admissions or declarations of a party in respect to the subject-matter of an action at law or suit in equity, may always be given in evidence against him. As distinguished from confessions, the term is applied to civil transactions, and to matters of fact in criminal cases where there is no criminal intent. Express or direct admissions are those which are made in direct terms. Incidental admissions are those made in some other connection, or involved in the admission of some other fact. Implied admissions are those which result from some act or failure to act of the party. To be considered as evidence, admissions may be made by a party to the record or one identified in interest with him, but not where the party of record is only a nominal party and has no active interest in the action.

Adobe, ä-dō'ba (Sp., from *adobar,* to daub or plaster), colloquially «dobie»: sun-dried bricks, from any native clays; especially those made in the arid western and southwestern regions of the United States, as in the Great Basin, Arizona, New Mexico, etc., by molding the bricks and then turning the sides alternately to the sun day by day for a week or two, stacking up for use when sufficiently baked. These, however, are the resource only of people in an inferior state of civilization, as the rain soon dissolves them into streams of mud; hence also they are impossible at all save where rain is very infrequent. The sizes are usually two, 18 x 9 x 4 and 16 x 12 x 4, the larger ones in the best building used as headers (the greatest length crosswise to the wall) and the others as stretchers (lengthwise). The earliest building material in Assyria and Egypt was adobe, usually strengthened with straw, and it is still much used in Japan and China. Adobe soils are clay soils very plastic when wet, but too hard for cultivation when dry; they are lightened by plowing in sand or sandy loam, and are often very fertile.

Adolescence, the period of human development which extends from puberty to mental and physical maturity. Clouston restricts puberty to the «initial development of the function of reproduction»; while, by adolescence, he denotes «the whole period of 12 years [about 13–25] from the first appearance up to the full perfection of the reproductive energy.» The period of adolescence is characterized by important anatomical, physiological, and mental changes which attend the development and the ripening of the adult individual. The first appearance of the reproductive functions, at puberty, is followed by a long process of gradual change during which the secondary sexual characteristics are matured and during which, also, general nervous functions are profoundly modified. The progress of adolescence depends somewhat upon sex — the female maturing slightly faster than the male — and upon racial and social conditions.

The mind of the youth, especially in the latter half of adolescence, discovers new instincts, new impulses, new powers of imagination and of sensibility. Along with the dawning consciousness of sex, come strong emotions and desires and a sense of novel relations and untried responsibilities. «The adolescent feels instinctively that he has now entered a new country, the face of which he does not know, but yet that is full of possibilities of good and happiness for him.» Ideals are formed, romantic situations imagined, and adventures planned. The feelings are unstable and are apt to fluctuate between excitement and depression. The boy is likely to develop a pronounced egotism, a longing for action, and a desire to impress persons of the opposite sex. The girl displays equally characteristic traits; such as sentimentality, coyness, self-sacrifice, and a craving for admiration. It should be remarked, however, that the adolescent consciousness is subject to wide individual variations. It is during this stage that individuality comes into prominence; for it is then that those hereditary tendencies which underlie temperament and character are fully realized. As a result, the youth attains not only a general sexual maturity but a definite personality as well.

But «bad» as well as «good» inheritance comes to light during adolescence; and, since it finds the developing organism in an exceedingly unstable equilibrium, the result is not infrequently physical and mental derangement. Various mental diseases — particularly mania and hysteria, which are marked by wide emotional disturbances — frequently appear during the latter half of the adolescent years (20–25). Some alienists recognize a distinct type of «adolescent insanity.»

Adolf of Nassau. See ADOLPHUS OF NASSAU.

Adolphus, or **Adolf, of Nassau,** Emperor of Germany: b. about 1250; d. 2 July 1298. He was elected emperor 1 May 1292, and was crowned at Aix-la-Chapelle 25 June in the same year. He owed his election in part to intrigues with the electors of Cologne and Mainz, who imposed on him the hardest conditions; but, refusing to fulfil them, he soon saw himself hated and deserted. Urged by want of money, he took £100,000 sterling from Edward I. of England to assist him against Philip the Fair of France; but obeyed the Pope's prohibition with alacrity. He thus made himself contemptible to the German princes, and became still more odious by taking advantage of the hatred of Albert, landgrave of Thuringia, against his sons, and purchasing this territory from him. This involved him in a fruitless five-years war to subjugate his purchase. Disgusted, and urged on by Albert of Austria, the majority of the

college of electors cited Adolphus before it; he failing to appear, the throne was declared vacant 23 June 1298, and Albert of Austria was elected. A war already existed between the rivals, in which Adolphus seemed superior until he was outmanœuvred and surrounded at Gallheim, and fell by Albert's own hand.

Adonai, a-dō'nAI, a Hebrew name for the Supreme Being; a plural form of Adon, «lord,» combined with the pronoun of the first person. In reading the Scriptures aloud, the Jews pronounce «Adonai» wherever the old name «Jhvh» is found in the text; and the name «Jehovah» has arisen out of the consonants of «Jhvh» with the vowel points of Adonai.

Adonijah, the fourth son of King David, by Haggith. His claim to the throne was best after Absalom's death, and the chief commander Joab and the high-priest Abiathar supported him; but the captain of the body-guard Benaiah, the priest Zadok, the prophet Nathan, and Solomon's mother Bathsheba, induced the old king David to make Solomon associate at once. Adonijah fled to the tabernacle for protection; but after the death of David he was slain by order of Solomon on the pretext that his request for a concubine of David's was a claim to the throne.

Adonis, a-dō'nis, in Greek legend, son of Myrrha, daughter of Cinyras king of Cyprus; born in Arabia. Before the birth of her son she was transformed into the tree which produces the fragrant gum called by her name; this, however, did not hinder his being brought into the world in due season. He grew up a model of manly beauty and was passionately beloved by Aphrodite (Venus), who quitted Olympus to dwell with him. Hunting was his favorite pursuit, until, having gone to the chase against the entreaties of his mistress, he was mortally wounded in the thigh by a wild boar. Venus, coming too late to his rescue, changed his blood into flowers. After death he was said to stand as high in the favor of Persephone (Proserpine) as before in that of Aphrodite; but, the latter being inconsolable, her rival generously consented that Adonis should spend half the year with his celestial, half with his infernal mistress. This is a highly decorated form: the simpler and older myth seems to have been that Aphrodite and Persephone contested the beautiful child's possession, and Zeus ordered that he should spend four months with each and four as he chose. The fable has been variously interpreted. The alternate abode of Adonis above and under the earth is typical of the burial of seed, which in due season rises above ground for the propagation of its species. How much of the myth was cause and how much result of the famous Greek woman's festival, the Adonia, cannot be said. This represented the union of Adonis and Aphrodite on one day and the sorrow over his death the other, and the women performed the funeral rites over small images of him; also planting quick-growing herbs like fennel and lettuce in shards filled with earth, and throwing them into springs after the burial. It was a worship of the reproductive principle of plants, which after a short life die and are buried and again spring up; naturally, it was involved with the grossnesses of phallic worship, for which all growth-cults tended to be an excuse. The name is Semitic, *adon,* «lord,» — though of course all the local gods were «adons» of the place,— and the cult was widespread in the East; in Phœnicia the Adon was termed Thammuz, «the hidden.» The Greek celebration was often performed by the priestesses of Aphrodite, courtesans; but Theocritus' charming Idyl XV. shows that in his time at least it was perfectly respectable for decent women to attend.

Adonis, a genus of plants of the natural order *Ranunculaceæ,* or crowfoot family. The genus is a native of Europe, and only a single species, *A. autumnalis,* the «pheasant's eye» of the flower-garden, is shown in the United States. It is a low leafy annual with scarlet or crimson flowers, darker in the centre. It is said to have been stained with the blood of Adonis.

Adoptian Controversy, The, one which arose in Spain toward the end of the 8th century. Its leaders were Felix, bishop of Urgel, and Elipand, archbishop of Toledo; they modified the doctrine of Nestorius (see NESTORIANISM) to the opinion that Christ was the Son of God only in his divine nature, and in his human nature only so by adoption. It was hoped that this doctrine would be more acceptable to the Mohammedans than the orthodox view, and a means toward their conversion; and Elipand was a zealous missionary among them. Felix introduced it into Frankish Spain, and Charlemagne called a synod at Regensburg (Ratisbon) in 792 to have him explain and justify it. Instead he renounced it, confirming the renunciation by a solemn oath to Adrian I., to whom the synod sent him; yet on returning to his diocese he taught it as before. Another synod was held at Frankfort in 794, and the doctrine was formally condemned, neither Felix nor any of his followers attending. After some controversy a commission of clergy was sent to Spain to put down the heresy. Leidrad, archbishop of Lyons, one of the commission, persuaded Felix to go before a synod at Aix-la-Chapelle in 799 and recant; which after a week's dispute with the great Alcuin he did, and was prevented from further relapse by being kept under surveillance at Lyons for the rest of his life, to 816. Elipand, at Toledo, maintained his Adoptian views despite their ban by the Church; but after his death they were abandoned by practically all. Occasional advocates afterward arose during the Middle Ages, however, and the question has been discussed even in modern times.

Adoption, the act of taking a stranger into one's family, as a son or daughter; or the taking of a person, a society, etc., into more intimate relations than formerly existed with another person or society; or the taking as one's own, with or without acknowledgment, an opinion, plan, etc., originating with another; also the selecting one from several courses open to a person's choice.

In law, both ancient and modern, the act of taking a stranger into one's family constituted the person so adopted one's heir to all intents and purposes. The practice was common among the Greeks and Romans, and is still in use among some modern nations.

A proceeding which so materially affects the succession of property and the rights of natural heirs is a very important one. It is not recognized by the common law of England, and exists only in the United States by special statute. Comparatively few of the States have engrafted it upon their systems of jurisprudence. But among many of the Continental nations it has been practised from the remotest antiquity. The effect of adoption was to cast the succession on the adopted in case the adopting father died intestate.

The statute in force in the State of Michigan is substantially similar to other statutes in the various States upon the subject. The Michigan statute provides, among other things, that the person or persons so adopting such child shall thereafter stand in the place of a parent or parents to such «child-in-law,» and be liable to all the duties, and entitled to all of the rights, of parents; and such child shall thereupon become an heir-at-law of such persons, the same as if he or she were in fact the child of such person or persons.

Adoption by matrimony is the placing the children of a former marriage on the same footing, with regard to inheritance, etc., as those of the present one.

Adoption by testament is the appointing of a person one's heir on condition of his assuming the name, arms, etc., of his benefactor.

Adoption by hair was performed by cutting off the hair of the person adopted and giving it to the adoptive father.

Adoption by arms was the presentation of arms by a prince to a brave man. These the recipient was expected to use for the protection of his benefactor.

In heraldry, arms of adoption are the heraldic arms received when the last representative of an expiring aristocratic family adopts a stranger to assume his armorial bearings and inherit his estates. The recipient may obtain permission from parliament to take the name of his benefactor, either appended to, or substituted for, his own.

In Scripture and theology, the act of admitting one into the family of God, or the state of being so admitted. The previous position of the person adopted in this manner was that of a «servant,» now he is a «son,» an «heir of God,» and a «joint heir with Christ.»

In ecclesiastical language, adoption by baptism is the act of becoming godfather or godmother to a child about to be baptized. Unlike real adoption, however, this does not constitute the child heir to its spiritual father or mother.

Adoration, in unspecialized modern usage, a spiritual homage to God; but originally an act to express obedience and reverence performed before the images of the gods. Among the Romans it was performed by raising the hand to the mouth, kissing it, and then waving it in the direction of the image; the devotee had his head covered except before Saturn and Hercules, and after the act turned himself around from left to right. Sometimes he kissed the feet or knees of the images. This homage was afterward transferred to the emperors, by bowing or kneeling, laying hold of the imperial robe, and then pressing the hand to the lips. The Oriental methods were of course still more abject,— bending the knee, falling on the face, striking the earth with the forehead, and kissing the ground or floor. Alexander borrowed this from the Persians and made it a feature of his court: the rough Macedonian Cassander burst into a roar of laughter when he saw the Persian grandees performing this *kotow* (the Chinese term for the same act) before Alexander, who was so enraged that he seized him by his long hair and dashed his head against the wall. But the Greeks considered it impious and degrading, and the best of them would not bend to it: Conon refused it to Artaxerxes, and Callisthenes to Alexander. The abject degradations which the mediæval far-Eastern rulers exacted from foreign traders, by submitting to which the Dutch purchased trade privileges, though the English would not,— crawling on the face from the door to the monarch's seat, licking up the dust as they went, till the victim was often unable to speak when he reached it, and could only gasp with his mouth full of dirt,— are well known. Milder forms in modern times, hardly thought degrading even by the sturdiest democrat, are kneeling and kissing the monarch's hand; and the similar homages of lovers have never been considered so. The ceremony of kissing the cross embroidered on the Pope's slipper is a like form, said to have been borrowed from a similar ceremony introduced by the emperor Diocletian, who greatly extended court ceremonial. The original signification of the word as an act and not an emotion is preserved in the marriage service of the English and Protestant Episcopal Churches, «with my body I thee worship.» In the Roman Catholic Church, also, a distinction is made between *latria*, the worship due to God alone, and *dulia* the veneration paid to the Saints, and *hyperdulia*, that accorded to the Virgin.

Adour, a river of southern France, having its source in the mountain ridge of the Tourmalet, in the department of Hautes-Pyrénées. Its course is first N., then W., S.W., and S.S.W., passing St. Sever and Dax, to the former of which it is navigable, and falling into the sea a little below Bayonne, flowing through many exceedingly fertile valleys. Its whole length is estimated at about 200 miles. The current is rapid, and sometimes serious inundations are caused by the melting of the snows on the slopes of the Pyrenees. At the mouth of the river there is a shifting bar.

Adowa, or **Adua**, Abyssinia, capital of Tigré; on the left bank of the Hassam, a tributary of the Tacazzé, 6,000 ft. above the sea, about 10 m. E. of Axum. It is the chief commercial depot on the great caravan route from Massowah to Gondar, about 110 m. from the former. Though it still carries on some trade and has manufactures of cotton cloths, iron, and brass ware, owing to the Abyssinian civil wars it has greatly declined from its former prosperity and presents a rather miserable appearance. The inhabitants, numbering about 4,000 in 1902, are considered the most civilized of the Abyssinians. It was here that the Italian Gen. Baratieri was defeated by the Negus Menelek, 1 March 1896, when 7,000 men, 250 officers, and the whole artillery were lost.

Adra (the ancient Abdera), a seaport of southern Spain, in the province of Almeria; 29 m. W.S.W. from the town of that name, near the mouth of the Adra, on an eminence facing the Mediterranean. The inhabitants are employed in agriculture, fishing, distilling brandy, and manufacturing lead from the ore produced from the extensive mines in the neighborhood. Pop. (1901) about 12,000.

Adragan'thin (from *adragant*, a corrupt form of *tragacanthe*), a gum, better known as bassorin (q.v.).

Adrar', Sahara, a district peopled by Berbers, possessing camels, sheep, and oxen, and cultivating dates, wheat, barley, and melons. Chief towns, Wadan, pop. 4,000, and Shingit, which has inexhaustible beds of rock-salt. The region embraces about 30,000 square miles and since 1892 is a part of the French possessions.

Adrastus, in Greek legend, king of Argos, son of Talaus and Lysimache. Polynices, being banished from Thebes by his brother Eteocles, fled to Argos, where he married Argia, daughter of Adrastus. The king assisted his son-in-law, and marched against Thebes with an army led by seven of his most famous generals. All perished in the war except Adrastus, who, with a few men saved from slaughter, fled to Athens and implored the aid of Theseus against the Thebans, who opposed the burying of the Argives fallen in battle. Theseus went to his assistance and was victorious. In a later story Adrastus after a long reign died from grief occasioned by the death of his son Ægialeus. He was worshipped at Sicyon, Megara, and Athens, perhaps also at Argos and the Troad. See Argos; Thebes.

Adrets, Baron des, Francis de Beaumont: b. Dauphiné, 1513; d. 1587; a violent French Huguenot, who distinguished himself by many daring exploits as well as cruelties. From 1562 on he made himself noted for a ferocity matching his opponents, but seemingly from no religious motive. He subsequently became a Catholic, but died as he had lived, in general detestation. At some places he obliged his prisoners to throw themselves from the battlements upon the pikes of his soldiers. Reproaching one for retreating twice from the fatal leap, « Sir,» replied the man. « I defy you, with all your bravery, to take it in three.» This keen rejoinder saved his life.

Adria, N. Italy, in the province of Rovigo, between the Po and Adige, is one of the oldest cities in Europe, having been founded by the Etruscans. So late as the 12th century A.D. it was a flourishing harbor on the Adriatic Sea, to which it gave name; but by the continual deposition of alluvium on the east coast of Italy it has been gradually separated from the sea, from which it is now 15 miles distant. It still retains several interesting remains of Etruscan and Roman antiquity, with a fine cathedral. It has a considerable trade in cattle, grain, and wine, silk, linen, leather, and pottery. Pop. (1900) 15,649.

Adrian, Emperor. See Hadrian.

Adrian I., Pope, b. Rome; succeeded Stephen III. in 772; d. 795. Like his predecessor, he had to struggle against the power of the Longobards, who had invaded the Exarchate and other provinces bestowed by Pepin, king of the Franks, on the Roman see. Adrian applied to Charlemagne for assistance against Desiderius, king of the Longobards. Charlemagne crossed the Alps, defeated Desiderius, and overthrew the Longobard kingdom in 774; he then went to Rome, where Adrian acknowledged him as king of Italy, and the latter renewed Pepin's grant. Charlemagne paid another visit to Adrian at Rome in 787, when his son Pepin was christened by the Pope. In 787 the seventh General Council of the Church was held at Nicæa. Adrian died after a pontificate of nearly 24 years. He was a man of talent and dexterity; he succeeded in gaining and preserving the friendship of the greatest sovereign of his time, and saved Rome from the last barbarian invaders of the Western Empire. He was the first Pope to change his name on election.

Adrian II., b. Rome; succeeded Nicholas I. 867; d. 872. He had been married and had a daughter by his wife Stephania, from whom he afterward separated in order to live in celibacy. During his pontificate Photius, Patriarch of Constantinople, withdrew from the Church of Rome; from which time dates the schism between the Greek and Latin Churches. He was succeeded by John VIII.

Adrian III., b. Rome; succeeded Marinus 884, and died the following year.

Adrian IV., the only Englishman ever raised to the papacy; succeeded Anastasius IV. 1154; d. 1 Sept. 1159. He was Nicholas Brakespeare, and for some time filled a mean situation in the monastery of St. Albans. Being refused the habit in that house, he went to France and became a clerk in the monastery of St. Rufus, of which he was afterward chosen abbot. Eugenius III. created him cardinal in 1146, and, in 1148 made him legate to Denmark and Norway, which he converted to Christianity. As Pope he granted to Henry II. a bull for the conquest of Ireland. In 1155 he excommunicated the king of Sicily; and about the same time the Emperor Frederick II., meeting him on a journey, held his stirrup while he mounted his horse. Adrian took the emperor with him and consecrated him king of the Romans in St. Peter's church. The next year the king of Sicily submitted and was absolved. His term was stormy: the Romans, influenced by Arnold of Brescia (whom he put to death), opposed him; his high claims for the papacy opened the long struggle with the Hohenstaufen house; and he was about to excommunicate Frederick II. when he died. He was succeeded by Alexander III.

Adrian V., a Genoese, succeeded Innocent in 1276, and died five weeks after his election. He was succeeded by John XX.

Adrian VI., succeeded Leo X. 1522; d. 1525. He was born at Utrecht, of an obscure family, advanced himself by his talents to the post of vice-chancellor of the University of Louvain. Ferdinand of Spain gave him the bishopric of Tortosa. After Ferdinand's death he was co-regent of Spain with Cardinal Ximenes. He was elected Pope chiefly through the influence of Charles V., whose authority was then spreading over Italy. He was succeeded by Clement VII.

Adrian, Mich., city and county-seat of Lenawee County. (Adrian's first name was Logan.) It was founded in 1825 by Addison J. Comstock, incorporated as a village in 1828, and as a city in 1833. Situated on the Raisin River, 30 miles from Toledo, and 59 miles from Detroit, at intersection of Lake Shore, Wabash and Detroit Southern R.R.'s. The branch lines of Lake Shore, to Jackson, to Detroit, and to Fayette, Ohio, terminate here.

Commerce and Manufactures.— Apart from its large business in agricultural products, Adrian has become an important manufacturing centre. It has extensive foundry and machine shops, and a large flouring mill. The Adrian Manufacturing Company, the American Electric Fuse Company, the Bond Steel Post Company, the Clough & Warren Company, and the Spring Brook Brewing Company are all large and flourishing concerns. Adrian saw the beginning of the woven wire fence industry, which was established here by J. Wallace Page in 1886. The Page Wire Fence Company was the pioneer in wire fence industry, and has become a great institution with its main factory here, and its wire mills at Monesson, Pa. Its output in 1904 was 17,543 miles of fence, with thousands of iron gates, employing in factories and mills 1,627 men. Another large fence company is the Lamb Wire Fence. Its output was $1,000,000 for 1904, with 150 employees, and running 25 fence looms. The Adrian, the Lion, and several other new companies are also manufacturers of wire fence. The factories of the Anthony and Globe Fence Companies are not far from Adrian. Capital used in the wire fence industry at Adrian is about $3,500,000, and the number of men employed is about 1,000.

Banks.— There are four State banks, with combined capital and surplus of $456,000, and deposits of $2,750,000.

Education and Religion.— City has fine system of public schools, with 2,700 pupils, and a public library of 20,000 volumes. Adrian College and a business college furnish higher education and business training. Adrian College is controlled by Methodist Protestants, has 300 students and six departments,— literature, theology, music, arts, manual training, and preparatory school. Saint Joseph's Academy, a school for girls, with 150 pupils, is conducted by the Sisters of the Order of Saint Dominic. The Industrial Home for Girls, a State institution for education and reformation of juvenile female offenders, is located here, with 353 inmates. There are many fine church edifices and a fine Y. M. C. A. building is under construction. Two daily and one weekly newspaper are published in Adrian.

Government, Population, etc.— The city government is by mayor and board of 12 aldermen. Adrian has system of sewerage, waterworks, and electric lights, paving, public steam heating, electric street car line, and a fine new post-office building. From its beautifully shaded streets, Adrian is called the Maple City. Pop. (1904) 10,680.

Charles R. Miller.

Adrian de Castel'lo (Adriano di Castelo, ä-drē-ä'nō dē käs-tel'ō). Italian cardinal and scholar: b. Corneto, Tuscany, c. 1460; d. 1521. He was educated at Rome; sent by Innocent VIII. to England, and to Scotland and reconciled James III. to his subjects; after that monarch's death at Sauchieburn he remained in England, and obtained a prebend and rectory from Henry VII. After Innocent's death in 1492 he returned to Rome and became prothonotary or secretary to Alexander VI. (Borgia), and finally cardinal just before Alexander's death in 1503. The story that Alexander fell a victim to his own attempt to poison Adrian in order to inherit his great fortune is scouted by recent historians. In 1502, in his absence Henry VII. made him bishop of Hereford, and in 1505 bishop of Bath and Wells. In 1517 he was involved in the plot of Cardinals Petrucci, De Sauli, and Riario to poison Leo X., confessed, and was absolved on condition of paying 25,000 ducats, though deprived of his cardinalate and English dignities. He fled from Rome, however, lived in retirement till Leo's death in 1521 (probably in Venice), and died suddenly on his way back to Rome, there being a suspicion that he was murdered by a servant. He is honorably remembered as one of the first who sought to rescue Latin from its mediæval corruptions and restore it to purity. He wrote a religious treatise 'De Vera Philosophia' (The True Philosophy, 1507, printed Cologne 1548); 'De Sermone Latino et Modo Latine Loquendi' (The Latin Speech and Mode of Speaking Latin, a scholarly work published at Rome in 1515, and repeatedly since).

A'driano'ple («Hadrian's city»), Turkey: its third city in size, next after Constantinople and Salonica; 137 m. W.N.W. of Constantinople, connected by rail; near the W. end of the great Thracian coast-plain where it rises to the Rhodope Mts.; at the confluence of the large Maritza (ancient Hebrus) which drains the centre of S. Bulgaria, the Tunja from the N., and the Arda from the W., all navigable. This position and the convergence of several trade routes have made it from very old times a place of great importance: it was an antique Thracian city, rebuilt by the emperor Hadrian, seized by the Turks under Amurath (Murad) I. in 1361, and the residence of the Sultans thence till the capture of Constantinople in 1453. Since the Russo-Turkish war of 1877–8 and the separation of Bulgaria, it has lost nearly half its population and a large part of its trade. The old wall that once surrounded it, now existent only in a few fragments, has been replaced by a circle of earthworks. It has a palace and two fine bazaars, besides schools and mosques. Pop. about 80,000, half Turks and the remainder Bulgarians, Greeks, Armenians, and Jews.

It has immense historic interest as the scene of three events of the first importance. (1) The battle of Adrianople, 9 Aug. 378, A.D., the most tremendous disaster to the Roman arms since Cannæ, and incomparably greater in permanent effects. The Goths, whose head chief was Fritigern,— a man of superior genius and honorable character,— were being crowded southward by the great movement of the Huns which culminated in Attila's occupancy of all central Europe three generations later, and asked leave to settle in the lands south of the Danube they had ravaged into semi-desolation. This was granted on condition that they came unarmed and left the children of the leading families in Roman hands as hostages; but when the Goths complied, the imperial officers, who were to supply them with food, forced them to pay famine prices for it, and sold or kept many of the girls for concubines. The enraged Goths, in return, carried

fire, sword, and plunder far down into Thrace; driven back for a time, they returned in the spring of 378, reinforced by Huns and Alans, and their vanguard came near Constantinople. The emperor Valens was an incompetent but ambitious man. Jealous of his brilliant nephew. Gratian, who had just won a great victory over the Western barbarians, and eager to fight before Gratian could join him and have the credit of a fresh victory, he made a long march on a sultry dog-day and attacked the Goths with his fatigued troops. The Alan and Sarmatian cavalry surrounded and hemmed in the Roman infantry, like Hannibal at Cannæ, till they could not use their weapons; thousands were driven into a marsh; the Roman army was practically exterminated; Valens was never again seen alive, and the Goths obtained permanent possession of the broad plains south of the Danube. (2) The Treaty of Adrianople, 1829. In the Russo-Turkish war of 1828-9, Diebitsch passed the Balkans, advanced on Constantinople, and halting at Adrianople made the demands of a conqueror, and the panic-stricken Turks acceded to everything. Russia received the N.E. coast of the Black Sea, and all rights over the Caucasus tribes, the district of Akhaltsikh, and the protectorate over Moldavia and Wallachia (now Rumania); and Turkey recognized the independence of Greece. (3) The Treaty of San Stefano (q.v.), after the capture of Osman's army defending Shipka Pass in the war of 1877-8.

Adriatic Sea, or **Gulf of Venice** (ancient Mare Adriaticum), an arm of the Mediterranean, stretching in a N.W. direction from the Straits of Otranto, between the E. coast of the Italian Peninsula, and the W. coasts of Turkey, Dalmatia, and Illyria; length, about 480 m.; average breadth, about 100 m.; area, estimated at about 60,000 sq. m.. Its depth in the north, between Istria and Venice, is only from 12 to 20 fathoms, but increases in proceeding south to 100 fathoms near its centre, and to 500 fathoms between its centre and its entrance. At the straits between Otranto and Valona its depth does not exceed 350 fathoms, but increases very rapidly toward the Ionian Sea. Its opposite shores present a striking contrast, the east being generally bold and rocky, lined with islands and furnished with good harbors, but thinly peopled and comparatively sterile; while the west are low, shallow, marshy, and ill provided with harbors, though generally populous and fertile. The Adriatic is evidently a continuation of the longitudinal valley of the Po, forming a long and narrow trough between the parallel ranges of the Apennines and the mountains of Illyria. The rivers which it receives, particularly the Po, its principal feeder, have produced, and are still producing, great geological changes in its basin by their alluvial deposits. Hence Adria, between the Po and the Adige, which gives the sea its name, though once a flourishing seaport, is now 15 miles inland. The principal trading ports on the Italian side are Brindisi, Bari, Ancona, and Venice; on the opposite side, Ragusa, Fiume, Pirano, Pola, and Trieste, particularly the last, which is the principal seaport of Austria and possesses a large trade.

Adsorption (a variation of the word "absorption.") The condensation of a gas or vapor upon the surface of a solid. The fact that solid bodies are capable of condensing upon their surfaces air films or gas films of considerable density was probably first forced upon the attention of the physicist by the difficulty of obtaining a permanently good vacuum. Thus it was found that a glass globe (for example) might be highly exhausted, and yet after a time the vacuum would be found to be materially reduced, even when it was apparently impossible that any air should have leaked in from without. It is now known that unless special pains are taken to prevent it, a film of air remains condensed against the surface of the glass, even when the vacuum through the general bulk of the globe is very high; and air molecules from this film are gradually given off until the vacuum becomes much less perfect than it was at first. To prevent this action it is customary to heat the vessel that is being exhausted, as the gas film is largely driven off from the walls of the vessel when they are heated. See VACUUM.

The condensation of gaseous films upon the surfaces of solids is undoubtedly due to the molecular attraction exerted by the solid upon the gas. This molecular attraction is insensible at distances that are easily measurable, but it may be very great at points sufficiently near to the surface of the solid. The expression "sensible molecular attraction," which is in use among physicists, is indefinite, and no very precise statement can be made with regard to the limiting distance beyond which the attraction is not sensible; but from the investigations of Quincke, Plateau, Maxwell, Kelvin, and others, we may infer, in a general way, that molecular attraction is not sensible at a greater distance than about 1-200,000th of an inch. Hence it is safe to say that this is the maximum thickness that the gas film condensed on a solid surface can have.

Concerning the condition of the gas in the film we can only say that where it is in immediate contact with the solid it probably has a very great density, this density rapidly falling off as we pass away from the solid. Under ordinary conditions of temperature the air film condensed against a solid cannot actually be in the liquid state, because it is not possible for air to exist in this state at any temperature higher than 220° below zero F. (See CRITICAL POINT.)

It is well known that a solid body appears to weigh less when it has been recently heated, or is still hot, than it does when it has been allowed to stand for some time in contact with the air at ordinary temperatures. This phenomenon is apparently due, to a considerable extent, to variations in the thickness of the film of air and moisture that the body condenses upon its surface. In accurate thermometry (see THERMOMETER), where the gas thermometer, is used as a standard, great pains are taken, in filling the thermometer bulb with gas, to avoid the contamination of the thermometric gas by moisture condensed upon the surface of the bulb; the bulb being repeatedly exhausted, heated, and refilled, until there is no longer the smallest chance of any appreciable part of the original surface film remaining. The phenomena of adsorption have not yet been fully studied.

Adullam, Palestine, a town in the Shephelah, or southwestern Judean coast-land; the centre of a Canaanitish clan later fused with Judahite Hebrews, but not till after David's time, when it was still "outside Judah," for which reason he and his 400 freebooters took refuge in

its « stronghold » (not « cave,» a misreading which has led to many fruitless identifications of site and a familiar English nickname — see below) when outlawed by Saul (1 Sam. xxii.). He also dwelt there when at war with the Philistines. Rehoboam fortified it. In Judas Maccabæus' time it was in « Idumæa,» as he stopped there when he raided that territory.

Adullamites, in English history, the Liberals who left their party in 1866 and joined the Conservatives, to oppose extension of the franchise by Mr. Gladstone and Earl Russell. John Bright in a speech compared them to the outlaws in the Cave of Adullam; to which Lord Elcho retorted that the band was hourly increasing, and would deliver the Parliament from the tyranny of Saul (Gladstone) and his armor-bearer (Bright). The group was also known as « The Cave.»

Adult Education. The provision for education of adults that is widely extending at the beginning of the 20th century is the logical consequence of the belief that universal education is a necessity in a democracy, and that it is essentially an organic part of the true political and social structure. The 19th century witnessed the spread of educational opportunities open to all. These opportunities are evidenced by the increase of the length of the school term; the lengthening of the period of school life of children; the establishment of compulsory education; the increase in number of public high schools, and the establishment of colleges and universities, maintained either by municipalities or States. These facts indicate that in a true democracy no limit is recognized in the field of education, and that educational opportunity should be open to all, regardless of age or sex. Philosophically speaking, the provision for education of adults can be justified on the ground that the mind reaches its maturity long after the school days end, and that much of the best and most effective work has been done by those who have passed beyond middle age. Provision for adult education, therefore, may be considered as having two distinct lines of development: First, to provide means for overcoming illiteracy, due to immigration or to insufficient education during the proper age; and second, a provision for a continuance of education as a means of culture, on the theory that education is life.

The first form of provision for adult education established by municipalities has been by evening schools, and such schools are found in the United States and the leading countries of western Europe. These schools are either elementary schools, in which the rudiments of an ordinary education are imparted, or high schools, in which systematic instruction is given in specialties. The term of these schools, taking New York city as an example, is from 90 to 120 nights, the session being two hours a night. There were, during the year 1902–3, in New York, 11 evening high schools, and 68 elementary schools, with an average attendance of about 25,000. The total enrollment of pupils in all the evening schools of the United States, from the latest report of the commissioner of education, was 190,000. A new law has just gone into effect in New York which compels boys between 14 and 16 years of age, who have not completed the regular day school course, but who are engaged in any useful employment or service, to attend the public evening schools for not less than six hours per week for a period not less than 16 weeks in each school year or calendar year. One of the most valuable features of evening school work, especially in great cities, is teaching the foreigners who come to these cities our language and our customs, and informing them of the nature of our government. More than 10,000 foreigners attended the evening schools of New York during the winter of 1902 for the purpose of studying the English language.

Courses of instruction are also provided for the supplementing of the education of workingmen. Types of these schools are the Mechanics' Institute in England, after the model established by Dr. Birkbeck; the continuation schools that are established in Prussia and other German cities, and in the United States by such institutions as the Cooper Union (q.v.) classes for science and art; the evening classes at the Pratt Institute (q.v.); the New York Trade Schools (q.v.), and the Hebrew Technical Institute. Instruction in these institutions is given on special lines and for the purpose of increasing the skill and general intelligence of the mechanic. In Germany this instruction is given either in the evening hours of week-days or on Sundays.

Education for adults for the larger purpose of adding to the general culture of the mass of the people has taken other forms during the past 20 years. In the United States the chief agents in adult education have been the Lowell Institute (q.v.); the Chautauquan Movement (q.v.); the University Extension Movement (q.v.); the Public Lecture Movement; and the work of such institutions as the Brooklyn Institute of Arts and Sciences; The People's Institute of New York; the League for Political Education; and the People's University Extension Society. The Lowell Institute was established in Boston in 1839, through the generosity of Mr. John Lowell, a merchant of Boston, who bequeathed half of his property to the support of public lectures for the benefit of his fellow citizens. The Lowell Institute has been the means of presenting the leading lecturers of the world to the citizens of Boston, and has provided courses, not alone for the general public, but lectures for more advanced students, including instruction in science to the school teachers of Boston, and has furnished instruction by lectures to workingmen in co-operation with the Wells Memorial Working Men's Institute.

The Chautauqua Literary and Scientific Circle was established in 1878, and had for its purpose the organization of adult education. In one of its earliest announcements it says: «It is for high school and college graduates; for people who never entered either high school or college. Several of the members are over 80 years of age, very few are under 18.» The features of the Chautauqua system of education are the general survey or college outlook; the four-years cycle and the unity of each year; that is, all readers in a given year read the same course. The course of studies includes history, natural science, and art. The seat of the Chautauqua Movement is Chautauqua, N. Y., where a great summer educational city annually assembles, and where religion and education go hand in hand. The number of local reading circles in the past

25 years has been about 10,000, and there are about 300 educational gatherings that are known as Chautauquas.

The movement known as University Extension is a general provision for the education of adults. Originating in England, the attention of the University Convocation in Albany, N. Y., July 1888, was called to the matter, and on 1 May 1891 a bill was signed by the governor, appropriating $10,000 for the New York State organization of University Extension. This grant is the first case on record of a State appropriation for University Extension. Under this appropriation courses of lectures controlled by university authority were arranged, and Library Extension by means of well-selected classified libraries, suiting local needs. The University Extension work now forms a part of the Home Education department of the University of the State of New York. According to the latest report, 394 courses of three or more lectures were given during the year 1900. The American Society for the Extension of University Teaching, which has its chief office at Philadelphia, has been in operation since 1890. In the 10 years from 1890 to 1900 over 5,000 lectures were given, with a total attendance of more than 1,000,000. The University of Chicago, immediately after its opening, took part in the University Extension movement, and now the extension division of the University of Chicago forms an important department of its work. All the non-resident work connected with the University of Chicago is conducted through the extension division by means of lecture study courses, correspondence courses, study clubs, and evening and Saturday classes, and in the year 1900 it gave 17 courses of lectures in 13 different public school buildings.

The Free Lecture Movement of New York, which is being followed in other cities, is the pioneer in an adaptation of University Extension in its best sense, to the purpose of educating all the people in a great city. The provision for the free lectures was made by an act of the legislature in New York in 1889, authorizing the board of education of New York to provide for lectures to working men and working women, and an appropriation of $15,000 was made for the first year. Lectures were at first given in six schoolhouses, and the attendance during the first winter was a little over 20,000. In the year 1902–3 lectures were given in 128 different places, including not alone the assembly halls of schools, but halls of museums and in many cases church halls, with an attendance of 1,207,000. The sum expended during the year 1902 was about $125,000, and New York therefore spends a greater sum than any other city for the education of adults.

This recognition by the board of education of a great city of adult education as an integral part of its educational system, and its support from the general school fund, marks a great educational advance. The lectures are divided into two classes. First, those intended to give general culture, under which are included lectures on travel and on music (abundantly illustrated either by stereopticon or vocal and instrumental music), and other lectures on history, science, art and literature, which are given in courses of from six to eighteen accompanied by a quiz, examination, syllabus and collateral reading. The lecturers include professors from the leading colleges and universities and other men who have become distinguished in their respective callings. Co-operation with the public library is established by means of lists of books posted in the various libraries which bear upon the lectures. A further extension of this work in New York has recently been made by the giving of lectures in Italian and other foreign languages to those ignorant of English, upon subjects relating to American life and institutions. As the population of our land is becoming more and more urban, the question of proper provision for adult education will gradually become more prominent in municipal administration, and the provision for such purpose can be defended on the ground of its necessity in a democracy and also as a means of furnishing rational joy to the people. The example of New York has been followed by many of the adjoining cities and also by Boston and Milwaukee. Some agencies of adult education in New York are:

(*a*) The People's Institute, which has its seat in Cooper Union and provides lectures of an economic, social, and ethical character and arranges for discussions on these subjects.

(*b*) The People's University Extension Society, which has been in existence since 1897 and works in co-operation with settlements, missions, mothers' clubs, and other institutions, and arranges lectures on hygiene and sanitation, the care of children, civics, and American history.

The Brooklyn Institute of Arts and Sciences received its charter in 1843, but began its greatest period of activity in 1887. This institute provides for courses of lectures in science and art, and maintains a library and art and science museum, and is supported by membership dues, and in the year 1901–2 the attendance at the lectures was 254,361. The city of New York in 1901 appropriated $300,000 toward the museum of this institution.

In the cause of adult education a very important factor now is the Young Men's Christian Association. Throughout the United States, courses of study for men are established in connection with all the main associations. Provision for instruction in mechanical subjects, literature, civil government, citizenship, form a feature of such courses of study. The league for Political Education in New York has for its special object the study of political and social science, and work for municipal and national progress, and maintains day lectures and classes for men and women, and evening lectures and classes primarily for men. The summer schools that have come into existence as a result of the Chautauqua movement form a valuable feature of adult education. Prominent among these schools in America is the Catholic Summer School which meets at Plattsburg, on Lake Champlain. The objects of the school are to increase the facilities for busy people, as well as for those of leisure, to pursue lines of study in various departments of knowledge, and opportunities for instruction are provided by lectures from eminent specialists. The Columbian Catholic Summer School assembles at Madison, Wis., and the summer assembly of the Jewish Chautauqua at Atlantic City. The University of Chicago recently adopted the summer school idea, and now academic work goes on during the entire year; and Harvard University and Columbia University both now maintain summer schools.

The recognition of the right of the adult to education will have its influence on the character of schoolhouses that hereafter are to be built, and already many of the newer school buildings in New York are equipped with auditoriums with ample provision for adults. Laboratories, too, will be provided in which further education in science may be given, so that technical instruction, such a great need in an industrial age, may be encouraged. The extension of the schoolhouse will make it, as Horace Mann said, not only a nursery for children but a place of intelligent resort for men. The public schoolhouse when used for the broad purpose of the instruction of youth and the education of the adult fulfills its real mission. See EDUCATION.

HENRY M. LEIPZIGER,
Supervisor of Lectures, New York Board of Education.

Adulteration («making otherwise»), deceiving buyers of goods as to their quality by secretly adding or taking away constituents. The element of deception must be present: openly selling any mixture, however poor, is not adulteration legally or morally. In usage the term is restricted to food products, drugs, and dyestuffs; the adulteration of coinage is termed «counterfeiting» (q.v.) that of unsound meat, fish, etc., «doctoring,» a term which, with «sophistication,» is also used for wines and liquors. Adulterated woolen fabrics are colloquially but not always properly known as «shoddy.» The object is to gain more profit: with costly wares, either by diluting them with cheaper ones, or by removing some valuable element for separate sale; with cheap ones, to make them look like or have the flavor of costlier ones; with spoiled or damaged ones, to make them appear sound. Most adulterations are not directly injurious to health, the public being cheated rather than poisoned, and it is to some extent a co-operator in the deception, as the cost of wholly pure articles would greatly curtail buying; on the other hand, it is often forced into such co-operation by inability to find or know the good when willing to pay for it, and wastes its money by paying for a pure article and receiving an adulterated one. And as the reduction of the nutritive value of food is itself a great evil; as the extent or harmfulness of adulterations cannot be known offhand, and tends always to grow worse as the maker grows greedier and his character deteriorates from losing his self-respect (itself a great social evil); as honest dealers are not only prejudiced by unfair competition, and suspected of fraud when qualities are poor, but often driven into the same course in self-defense; and as hasty additions of cheap materials are always liable to come from diseased sources and menace public safety,— modern legislation constantly broadens its scope in dealing with this offense alike from a pecuniary, a sanitary, and a moral standpoint. Ignorance is no excuse to a dealer who sells adulterated wares under the ordinary trade title: it is a fraud at common law, and he may be compelled to take back the goods or pay damages.

The history of adulteration would probably be coexistent with that of trade. We know that it was practised by the Greeks and Romans, and the comic dramatists have diverting references to the «doctoring» of stale fish. English statutes exist from 1266 with penalties for debasing beer or wine and selling inferior bread or meat, while tea (see below) had later a special statute; and the law-makers have never ceased struggling with the problem. But the first great general agitation was in 1851, when the London *Lancet* produced a great effect by a special investigation and publishing analyses and names of dealers, and the first parliamentary commission was appointed. The first general adulteration act was passed in 1860.

The chief articles subject to adulteration have been, first of course the great staples of life, flour and bread, milk, butter, and cheese, with beer, wines, liquors, and tobacco, staple in use if not need; relishes and seasonings, as sugar, honey, preserves, vinegar, pickles, condiments, and spices; oil and lard; tea, coffee, cocoa, and chocolate; confectionery; drugs and dyestuffs. The selection and extent of adulterations vary indefinitely with place and time: as cost or popular wealth differs in different countries and epochs, adulterations common in one place or generation are almost unknown in another.

Beer.— The objects of its adulteration are three: to give artificial strength to weak beer, to disguise the badness of poor or spoiled beer, and to keep it from spoiling. The mineral adulterants used have been among the worst possible, as arsenic (the cause of some known deaths and very likely others) and sulphate of copper. Picric and salicylic acids are used for disguise: the latter is prohibited in Germany and is certainly liable to injure the digestive system. Alum, potash, cream of tartar, and salt, used to make beer keep, are not regarded as deleterious adulterants proper. Wild cherries, flaxseed, various herbs and foliages, etc., are employed,— cheats but not injurious.

Butter.— A formidable list may be made of the butter adulterants at different times and places,— chalk, gypsum, alum, and borax, boracic and salicylic acids, glucose, flour, etc.; but for practical purposes they may be reduced to water, buttermilk, cheese, salt, and oleomargarine (q.v.) as increasers of bulk, with arnotto, aniline yellow, etc., to improve the color. The latter is hardly adulteration either in bad intent or bad effect: the public universally connects a yellow tint with richness in cream,— quite irrationally, as the milk of many cows gives butter as white as tallow, yet of perfect quality and taste,— and the harmless pigments merely remove incorrect prejudices. The first four others are equally innocuous (save that buttermilk makes it grow rancid more quickly: it is usually carelessness or incompetence rather than fraud), and are mere diluents. In normal butter, water should not exceed 12 per cent and salt 5 per cent. Oleomargarine is not even an inferior product in any respect: its nutritive value equals that of butter, and it keeps better; and the severity of the laws regulating its manufacture and inspection guarantee its quality beyond that of any other manufactured article. Only a small percentage is directly bought for table use, the vast majority being sold to dairymen to churn with their cream into ostensible butter. Its use as an adulterant concerns business interests, not public health.

Cheese.— American and English cheeses are practically not adulterated. Fancy foreign cheeses, as the Swiss, etc., often contain coloring matter and potato meal.

Cocoa and Chocolate.— The chief adulterants are starch and sugar; but they have also contained wheat and potato flour, sawdust, oils and fats, and other things. The tests are for theobromine (the characteristic principle of the cacao bean), fat, starch, inorganic matter, etc.

Coffee.— Its usual adulterations are seeds (roasted peas, beans, etc.), or roots (chicory, dandelion, carrots, turnips, parsnips, etc.), with caramel to color their gray tint. All these are mere diluents; though there are some who actually prefer an admixture of chicory for its flavor, though it gives black, bitter, and muddy grounds. It and the roots may be easily detected by putting a little of the sample into a glass of water: each bit of chicory or other root will be soon the centre of a yellowish-brown cloud, which will rapidly spread till the water is all colored. There are also chemical tests for both tea and coffee, by determining the amount of theine or caffeine, the percentage of matter soluble in water, treatment with hot mineral acids which increase the sugar in coffee but not in chicory, etc.

Confectionery.— The extreme cheapness of sugar has practically put an end to the adulteration of all but the very poorest grades of candies; and those mainly with the harmless terra alba, or pipe-clay.

Distilled Liquors.— Whiskey, brandy, and rum are often purely factitious, being made from caramel and dilute alcohol, and given the characteristic flavors by ethers of various sorts and fusel oil (often left in genuine whiskeys, etc., from carelessness or grudging the cost of purification, and recognizable by its nauseous smell when a little of it is evaporated in the hand).

Drugs.— The adulteration in each case is special, with some article looking like the genuine but inert. This is of course potential manslaughter wholesale, as each prescription made from such materials might cost a life. Unfortunately, a large part of the drugs are imported, and the fraud is probably committed before they come to this country at all.

Dyestuffs.— These are very variously adulterated with cheaper dyes, determinable if at all by expert chemical examination.

Flour and Bread.— Flour is not much adulterated in the United States, though it is in Europe, where the masses are poorer. The chief admixture is ground gypsum or other minerals, which can be detected with the microscope; diluents but harmless. The chief illegitimate additions to bread are alum and sulphate of copper, to whiten it or correct sourness. Alum in baking-powder is not thought objectionable, the heat of baking converting the mixture into insoluble aluminum phosphate; and by itself its chief harm is in disguising the sourness of the bread. Copper sulphate is always dangerous. Both are tested by dissolving gelatine, laid for some hours on a sop of the bread, in a wood-alcohol tincture of logwood with ammonium carbonate, which turns blue for alum and green for the copper salt.

Honey.— Strained honey, a costly article when pure, is heavily adulterated with glucose syrup and sugar, cane sugar, corn-starch, etc. The taste is a better guide to these than any analysis, as that of native flower-fed honey is beyond counterfeiting; but chemical analysis can detect most of them. Still better is the buying of comb honey. The charge has been made by English chemists that American combs are often made of paraffine and filled with glucose; this is most improbable, but a very simple test will decide it. The microscope will show pollen grains in the real, and warm sulphuric acid will blacken beeswax but not paraffine.

Lard.— Hogs' lard is adulterated with stearine, tallow, and cottonseed oil; other vegetable oils, and the lard from animals dying a natural death, are sometimes added, but have no commercial importance if true.

Milk.— The adulterations of this are reducible to five: diluting, skimming, replacing the skimmed cream with cheaper animal fats, coloring to give it the look of that cream, and adding preservatives or correctives to keep it from souring or to sweeten its taste when beginning to turn. Its use as the staff of life for millions of children and invalids makes its purity one of the most exigent demands, and its bad quality or innutritiousness a cause of enormous amounts of disease and death. In some great cities pure milk is simply not attainable for the masses at any price within the means even of ordinary workmen: the dairy districts within reach of the city by train, during any time it will keep sweet and not churn, cannot supply enough for all, and it is inevitably diluted with water, and more or less of it treated with chemicals. To this is added what is not at all necessary, the skimming off of the cream to sell separately; both the first and the last heavily reducing its nutritive value. Still worse, the water used is always liable to contamination from discharges of diseased bodies (diphtheria, typhoid, and scarlet-fever outbreaks have been repeatedly traced to this cause, sometimes merely from cooling leaky cans in the tainted water), from decaying animal or vegetable matter, or from the germs with which street dirt is laden. (The contamination from sores on cows kept in unsanitary conditions belongs to another subject.) As to the effect of the adulterations: Skim-milk is a cheap and valuable food for blood-making protein, as evinced by the cheese made from it; but it should be sold as such, otherwise infants and invalids who need the cream may be injured. The fats simply do not replace the characteristic and valuable qualities of the cream. Of the chemicals, formaldehyde (also used for preserving other foods) is dangerous and should not be permitted. Borax, salt, and carbonate of soda are also used; neither they nor the arnotto used to give the milk a cream color are harmful in themselves, but only as disguising the real quality of the milk sold. Chalk and calves' brains are probably jocular figments.

The method of testing for dilution is by the lactometer, to determine specific gravity, which is lowered by admixture of water; in exact reverse, it detects skimming (which increases specific gravity by removing the lighter cream) by showing normal specific gravity when looks and taste are inferior. Skimming is also inferred from increase in transparency, as indicated by the lactoscope: opaque normal milk needs thinning with a certain percentage of water before a dark object, or black line drawn on a

white surface, will show through; the less water a given sample needs for this visibility, the less cream it contains. For more precise determination the chemist finds the amount of solids in a sample by evaporating a mixture of milk and heated sand and weighing the residue; the amount of fats, by dissolving them out with ether and evaporating. Watering may often be detected by testing for nitrates, which milk does not contain and most water does, and contaminated water almost always. The detection of animal fats used to replace cream is not easy, though the butyrates have some individual qualities.

Mustard.— This is perhaps the most heavily and universally adulterated article in the market: only a small percentage of it is pure, and even that has had its abundant essential oil, which makes it difficult to grind, expressed from it. For one harmless adulteration the public is responsible, as for butter-color and pickle-green: that of turmeric or ochre to give it the bright yellow demanded by customers, while real mustard is very dull. But it is regularly diluted with starch,— wheat, corn, or rice,— rape-seed, flaxseed, old turnip- or radish-seed unfit to plant. For starch, easy tests are iodine, which turns it blue, and its thickening in boiling water; for mineral matter, the chemist determines the amount of ash. For the others, though the microscope is useful, the best remedy is to pay for a known brand,— which indeed is best for all.

Oil.— A large part of the so-called olive oil of the market is cottonseed, peanut, or mustard oil, or greatly mixed with it: probably the equal in quality and taste of the genuine (as it is indistinguishable), but a fraud as exorbitant in price through deception. The use of lard oil is probably a figment, that of petroleum oils certainly so. Tests: Nitric acid colors the adulterant oils, but not olive, and sulphuric acid raises their temperature higher.

Pickles and Canned Goods.— The public demand for bright green pickles has been gratified by boiling them in copper kettles with vinegar and some alum, the vinegar forming the highly poisonous acetate of copper with the kettle, and coloring the pickles green: it is easily tested by dipping a piece of clean bright iron in the pickle, which will gain a coating of copper if it is present. The same process is said to be gone through with peas; and even the copper salts directly added, which would be a basis for a criminal prosecution. The presence of metallic salts from the can — which would result from careless canning and not deliberate addition — has been thoroughly demonstrated to be harmless: oxid of tin would make the canned food too nauseous to eat long before it reached even a medicinal proportion, and oxid of lead has not been found in any quantity. By far the greatest danger in canned foods is bad canning, causing putrefactive ptomaines to be created, which have caused many deaths.

Preserves, Jams, Jellies.— Gelatine and glue are often used to help the fruit to jelly (not always an easy thing to assure even by experts), and are often not restricted to the amount needed: the goods are also artificially colored, and flavored with so-called «fruit oils,» chemical analysis being needed to determine the constituents. Zinc oxid has been found in preserves, from its use to make covers of jars air-tight.

Spices: Nutmeg, Pepper, Cinnamon, Mace, Cloves, Allspice, etc.— Whole spices are generally thought safe from adulteration; but they are not, as inferior members of the same species may be substituted for them, with immense loss of quality, exactly as if crab-apples were sold for dessert apples. Thus, wild nutmegs are often sold for the cultivated ones, and cassia almost always for cinnamon. The method of detection is to know the genuine. For instance, the best nutmegs are about an inch long and shaped like a damson plum, weigh one-seventh to one-fifth of an ounce, and exude oil liberally when pricked with a pin; the wild ones are small and pointed and have less oil and fragrance. The genuine or Ceylon cinnamon is a thin small roll, of delicate fragrance which lasts long in the mouth, and tears rather than breaks; the cassia or Chinese cinnamon is much coarser and thicker, breaks but does not tear, is rather mucilaginous when chewed, and has a strong woody flavor. In 1875 the United States imported $4,073 worth of cinnamon and $279,250 worth of cassia, or nearly seventy times as much. Cloves are adulterated by making them absorb water, of which they will take up a great deal, to increase their weight.

The immense adulteration of ground spices makes their convenience a costly purchase. At the outset, sawdust and starch are added even to the best, to absorb the oil which makes them difficult to grind; and it rarely stops there. Of 12 specimens called « ground cinnamon » examined by the New York Board of Health in 1883, only three contained any cinnamon whatever, and even those were largely mixed with cassia and sawdust; the others were almost entirely composed of those ingredients, two were sawdust with a very little cassia, and one was pure sawdust. Seventy per cent of the allspice, 70 per cent of the pepper, 82 per cent of the cinnamon, 57 per cent of the cassia, 76 per cent of the cloves, and 66 per cent of the ginger, was adulterated. The most universal adulterations are starch for bulk, mustard for pungency, and turmeric for color. Black pepper demands a special note, as it is the exception rather than the rule to find it pure. A large percentage of the samples examined in the past have contained no pepper at all. « Pepper dust » (the sweepings of warehouses, in trade a regular article of sale as « P. D.»), mustard husks, ground wheat, corn, or rice, capsicum, and even gypsum and sand, have been found in it. Red or cayenne pepper is much purer than black pepper and is mainly adulterated with flour.

Sugar.— White cane sugar has become so cheap that it does not pay to adulterate it, and the old adulterants like marble dust, terra alba, etc., have practically disappeared except in cheap confectionery. Sand was never much used except in brown sugar (4 per cent has been said to be unavoidable in Manila sugars, but any percentage is indictable if the direct addition can be proved), and glucose from sawdust has taken its place: equally healthful with cane sugar, but of course a fraud as less sweet and a deception.

Tea.— Owing to its cost and the difficulty of judging its quality by the eye or taste (Adam Smith has some acute remarks on this), tea has always been a favorite article of adulteration

from its introduction into the West; fortunately, more than most products the price is an index of the quality, and it is easy to procure a good article by paying for it, the supply of good quality not being limited by nature as with foreign wines. It has the distinction of having had a special law passed to prevent its adulteration, and for the most curious reason imaginable: the Act of 17 Geo. III. alleges that the admixture of the leaves of sloe, ash, elder, and other trees and shrubs with it was working great injury to the timber and undergrowth. Being a luxury whose cost presses heavily on the very poor, its substitutes within the means of that class have usually none of the characteristic properties, good or bad, of the genuine, and are mere flavored warm drinks; curiously, the only poisonous adulteration ever alleged against it (groundlessly), that of obtaining its green color from copper pans, was against the very costliest brand of all. It has been said, however, that tea was « faced » with Prussian blue and indigo; if so, the time has gone by. But the stuff sold to the poor, besides spent tea-leaves, and those of various plants as above, has been found to contain masses of sheer dirt, sweepings, brick-dust, etc., unwholesome and liable to contain disease germs. See TEA.

Tobacco.— Color and flavor are often given to inferior grades by artificial means. No leaf is known which will counterfeit the tobacco leaf outright. Snuff, however, lends itself readily to debasement by colored powder, and lime and chromate of lead have been found in it.

Vinegar.— The most usual form of adulteration is thinning down with water, then restoring the lost strength with sulphuric, muriatic, nitric, or other cheap mineral acids. The first is easily detected by the considerable precipitate when barium chloride is added; the second by a white flocculent precipitate on adding a few drops of solution of silver nitrate. Nitric acid needs special chemical tests.

Wines.— Naturally their chief adulterants are water and alcohol, to increase bulk or strength; colors and flavors, astringents, etc.,— caramel, logwood, glycerine, syrups, etc.,— to give artificial qualities resembling reputed wines; salicylic acid to prevent souring; gypsum to precipitate organic matters that muddy the wine (the latter injurious as likely to turn into acid potassium sulphate); sugar in the must, to increase the alcohol, etc. Natural colors like fruit juices and cochineal are harmless; aniline colors not always. The chemical tests are too special to be detailed in a popular work. It should be said, however, that by far the leading adulteration consists in the wine not being real fermented grape-juice at all: this applies only to foreign wines, the American being generally pure, and practically the only pure wines at moderate price on the market. Real wine from foreign vineyards is a costly article, and the better grades are pledged years ahead to the great foreign courts, noble houses, and private European buyers. Cheap foreign wines should be understood from the outset to be made either from exhausted grape-skins or raisins treated with alcohol and water (it is not for dessert use that the great majority of the California raisin crop is exported to France), or from pear-juice (much the greater part of the so-called French « champagne » in America being perry).

(Ellen H. Richards, ‹Food Materials and Their Adulterations,› an admirable household manual of food selection and preparation, Boston 1886; ‹Health in Diet, Health Exhibition Literature,› Vol. V., London 1884; Battershall, ‹Food Adulteration and its Detection,› New York 1887; Wedderburn, popular treatise on ‹Food Adulterations,› Washington 1890; Wiley, Richardson, Crampton, and Spencer, ‹Foods and Food Adulterants,› 7 parts, Washington 1887–92; etc.)

Adultery, unlawful intercourse between two married persons not standing to each other in the relation of husband and wife, or between a married person and another unmarried. In the former case, it has been called double, and in the latter single adultery. Unlawful voluntary sexual intercourse between two persons, one of whom at least is married, is the essence of the crime in all cases. In general it is sufficient if either party is married, and the crime of the married party will be adultery, while that of the unmarried party will be fornication. In the United States there is a wide diversity in the laws relating to this offense. In some States it has been made a crime, while in others civil proceedings are allowed substantially similar to those of the English law. Varied punishments, mostly of a very severe character, have in nearly all countries and ages been inflicted on those who have committed this offense. In some cases it has been deemed lawful for a husband or the woman's father to kill the guilty person if taken in the act. By the law of England the slaughter of the offending parties in such cases is deemed manslaughter of a not very aggravated sort. In English law the act is punishable only by the censure of the ecclesiastical courts, but when committed by a wife it is regarded as a civil injury, and an action for criminal conversation may be brought by the husband against the paramour. Adultery is now considered in England a ground for total divorce.

Advance Guard. See TACTICS.

Advaita, ä-dwaī'tä, a philosophical school of India, founded by Sankarûjûrya (or Cankarâcârya), who flourished about the middle of the 8th century A.D., or earlier. Its principal doctrines are that the human soul is not essentially different from God, but that it is imprisoned in the body from which at death it is released to return to the impersonal God, and that the material world is not different from God. Its adherents are called Advaïtavâdin, or Confessors of Monism.

Ad Valor'em (« according to value »), a term denoting the method by which customs taxes are determined at a percentage of the value of the imported article at its place of export, on the seller's oath and the appraiser's estimate. Theoretically, this is much fairer than a specific duty (on a unit of measure, as pound, yard, bushel, bale, etc.), since the costlier pay their equal percentage with the cheaper; but in practice, it has serious drawbacks, annoys both sellers and government much, defrauds the latter somewhat and its people a great deal. Values are unstable, the exporter is interested to understate them, and the officials are eager to scent fraud, whence much friction and many lawsuits. As to the last item, general tariffs are apt to produce an appearance of moderate aver-

age by equating a low duty on grades of slight consumption with a high one on those chiefly used; a deception impossible on specific duties, which at least must declare themselves. The customs officers much prefer these also. The United States tariffs are of both kinds, some articles having a combination of the two.

Advancement, in law, is a gift by anticipation from a parent to a child of the whole or a part of what it is supposed such child would inherit on the death of the parent. An advancement can only be made by a parent to a child (2 Jones, 137), or in some States by statute to a grandchild. (4 Kent Comm. 419.) The effect of an advancement is to reduce the distributive share of the child by the amount so received, estimating its value at the time of receipt. In some States, however, the child has his option to retain the advancement and abandon his distributive share.

Advancement of Learning, The, by Francis Bacon, 1605, the original title being ‹Of the Proficience and Advancement of Learning, Divine and Human.› This book, received with great favor by the court and by scholars, was afterward enlarged and published in Latin with the title ‹De Augmentis Scientiarum,› as the first part of a monumental labor, ‹The Instauration of the Sciences,› of which the second part was the still famous ‹Novum Organum,› on which Bacon's fame as a philosopher rests.

Advent, the period of some weeks before the Nativity, observed in all the apostolic churches as a season of solemnity of emotion and action, marriages and public amusements being interdicted or reprobated; in the Roman Catholic Church also a season of fasting and penance. In the Western Churches — Roman, Lutheran, English, and Protestant Episcopal — it is of four weeks, beginning the Sunday next after 26 November, or that nearest St. Andrew's Day (30 November); in the Greek Church it is six weeks, beginning 11 November, St. Martin's Day. Our first notice of it is in the 6th century, at the Synod of Lerida (524); and two sermons on it in 542 show that it was then in general observance. In that century also the Eastern and Western Churches, following the Nestorians, made it the beginning of the ecclesiastical year instead of Easter. Its four Sundays were believed to have been introduced into the calendar by Gregory the Great; and to have reference to Christ's fourfold coming early spoken of — in the flesh, at the hour of death to his faithful followers, at the fall of Jerusalem, and at the day of judgment. On these grounds the gospels were chosen for the four Sundays. Its ordering was settled in the Western Church by Charlemagne's « Homilarium.»

Advent, Second. See MILLENNIUM.

Adventists (often spoken of as « Second-Adventists,» and formerly as « Millerites »), a sect founded by William Miller (q.v.), beginning with his preaching in 1831, on no doctrinal creed or theory of ritual or church government, but the belief in the speedy coming of Christ to reign on the earth: a persuasion shared by so many hundred thousands in many sects,— forming indeed an essential foundation-stone of one considerable body, the Catholic Apostolic,— that it hardly seems a basis for a separate church; and in fact it is not one, but six, each with a special creed and organization. Mr. Miller's study of the Biblical prophecies, especially the Book of Daniel, had convinced him that the coming was to be between 21 March 1843 and 21 March 1844; after this time had passed, he was led to believe that he had erred by a year through mistaking the Jewish year for the Roman, which would be 1844, the exact date (the prophecies having given it even to an hour if we understood them) being 24–5 October. Vast multitudes, many being first baptized by immersion, assembled in different places (one group on an island in the Connecticut River above Hartford) to welcome the occasion and the Saviour (not however in ascension robes, as usually stated, or not generally); one lady went to Palestine to meet her Saviour first; some in the fervor of their faith gave away their property; and the excitement scarcely flagged till far into November. There was a « Shut-Door » faction, who believed that on the tenth day Christ had shut the door, and the « tenth-day » debate and literature were considerable; one of « Feet-Washers"; and in the shock of disappointment, the Shakers received considerable accessions. On 20 April 1845 Mr. Miller called a convention at Albany, N. Y., of the still faithful (over 50,000 in all), which issued a declaration of belief and adopted the name of Adventists. The declaration was that Christ will come soon, but at an unknown time; that the dead both just and unjust will arise, and with the resurrection of the saints the Millennium will begin; but that there is no promise of the world's conversion, and the saints do not enter into their inheritance at death. Mr. Miller died in 1849, but the sect has maintained its vitality with remarkable persistence in the face of repeated disappointments, several other periods having aroused wide hopes among them. They now, however, in general fix no specific date, but like their fellows in other Churches await the hour in the Lord's good time. Their Church government is congregational, save that the Seventh Day Adventists and the Church of God (originally one) have a general conference which is supreme. Their baptism is by immersion.

Their branches are: (1) The Evangelical Adventists, formed 1845, who believe in the resurrection of the saints first to eternal bliss, and the wicked last to eternal torment, but that all are conscious after death while waiting. (2) The Advent Christians, organized 1861, who believe that the dead are unconscious, that the wicked are punished by annihilation, and that salvation is free to all who meet its conditions before death. They are chiefly located in New England, and their literature is published by the American Millennial Association, Boston. They maintain home and extensive foreign missions; the former aided by the "Helpers' Union," a woman's auxiliary. (3) The Seventh-Day Adventists (q.v.), formed in 1845, who believe as (2) concerning the dead; that the gift of prophecy still exists, and was accorded to Mrs. Ellen G. White; that the United States is the Two-Horned Beast; that 1843 was a real fulfillment of prophecy, namely, the « cleansing of the sanctuary » and the beginning of the « investigative judgment »; and that total abstinence, vegetarianism, and hygiene are part of religion. This is by far the strongest of all. Its headquarters are at Battle

Creek, Mich., and its members are spread throughout the United States, being especially strong in the West, and numerous in other countries as well as America, having a missionary society active in all parts of the globe. It has seven publishing houses, in America, Europe, and Australia, and sanitariums and seminaries in a number of States. Its members are spread throughout the Atlantic States. Four camp-meetings are held each year, in New England and Virginia. Home missions are supported by an adult and a juvenile society. The publishing house is at Springfield, Mass. (4) The Church of God, formed 1864–5 by a split from (3), on refusal to hold Mrs. White inspired or the United States the Beast; otherwise its beliefs are the same. It is located chiefly in the West and Southwest, and has a publishing house at White Cloud, Mich., and a sanitarium at Stanberry, Mo. (5) The Life and Advent Union, organized 1860, which believes that the wicked never wake from their sleep of death. (6) The Churches of God in Jesus Christ (« Age-to-Come Adventists »), who believe in the establishment of the kingdom of God on earth, with Christ as king and the saints partakers with him, the annihilation of the wicked, and the restoration of Israel. They are established in various parts of the United States and Canada.

The following is a summary of the size and activities of the various United States Adventist bodies in 1900: —

Denominations.	Churches.	Ministers.	Communicants.
1. Evangelicals	30	34	1,147
2. Advent Christians ...	610	912	26,500
3. Seventh Day	1,494	386	57,539
4. Church of God......	26	19	647
5. Life and Advent Union	28	60	3,800
6. Churches of God in Jesus Christ	95	94	2,872

Adverb. See GRAMMAR.

Adverse Possession, a possession against any other claimant. It is the enjoyment of land, or such estate as lies in grant, under such circumstances as indicate that such enjoyment has commenced and continued under an assertion or color of right on the part of the possessor.

In a majority of the States of the Union, when such possession has been actual and has been adverse for 20 years, of which the jury are to judge from the circumstances, the law raises a presumption of a grant. This presumption, however, arises only when the use or occupation would otherwise have been unlawful.

Such possession, however, must be open, notorious, visible, exclusive, and continuous. But possession is not adverse when both parties claim under the same title, as if a man seized of certain land in fee have issue two sons and die seised, and one of the sons enter by abatement into the land, the statute of limitations will not operate against the other son; for when the abator entered into the land of his father, before entry made by his brother, the law intends that he entered claiming as heir to his father, by which title the other son also claims.

Adversity Hume. See HUME, JOSEPH.

Advertisements of Elizabeth, orders issued by Matthew Parker, Archbishop of Canterbury, in 1566, to enforce dignity and uniformity in the conduct of Common Prayer and the administration of the sacraments; prescribing the wearing of the surplice and college cap by the clergy, and of the cope in cathedrals and collegiate churches. They were so entirely in accord with Elizabeth's known views that the Archbishop had no doubt of her sanction; but after a year's waiting and copious correspondence with her minister Cecil (Burghley), he could not extract an official guaranty and was obliged to assume personal responsibility. Their modern importance springs from the quarrel in the English Church over ritual and their varying interpretation by the High and Low parties. In the Ridsdale case of 1877, the latter, headed by Lord Selborne, held that they prescribed absolutely the vestments to be worn, and were infringed by additions; the former, through James Parker, held them merely a minimum for decency.

Advertising. From French *Avertir,* to notify. Originally, advertising implied mere publication, a notice for an individual, or class, such as legal advertisements. The word, however, is now generally applied to the advertisement of merchandise to the public at large, through periodicals, circulars, posters, painted signs, electrical display, etc. In its present sense advertising is a powerful and legitimate force in the commercial world and in the distribution of commodities, and it has been designated as the literature of persuasion. Its volume in the United States figured in dollars is greater than any other line of business except banking, insurance and transportation.

History of Advertising.— The rudiments of advertising as it is practised to-day for the promotion of commerce can be traced back as far as commerce itself. With the invention of the rudest forms of writing came advertisements such as the rewards for runaway slaves. These were written on papyri and well-preserved copies have been exhumed at Thebes. Before writing was developed advertising by means of criers and sign-boards existed. The latter have been used in all ages for the information of the illiterate. Shops in ancient Pompeii had terra-cotta signs, showing a goat to denote a milk-seller's stall, or two men at sword-play to indicate a fencing school. Old tavern signs like the « Star and Garter » are a mediæval form of the same species of advertisement. All shops in London and Paris had such picture-advertisements in the Middle Ages, so that servants unable to read might find them. Until the invention of printing advertising was necessarily of this primitive character. But since the 16th century it has steadily kept pace with the increase in periodicals and books. The oldest newspaper advertisement preserved appears in a German newsbook of 1591, and is a book notice. The first newspaper traceable in France (1612) was partly an advertising medium. The first English newspaper appeared in 1622, and the first advertisement 30 years later. But before that the puffing of books, shows, cure-alls and quacks by posters, processions, etc., was very common. The introduction of tea, coffee and chocolate into England is recorded in old newspaper advertisements (1652–58). Addison's «Tatler» No. 224 (1710) is devoted entirely to descriptions of advertisements of that day in the public press, and tells of methods of exploiting

pills, plasters, cosmetics, books, houses for rent and advertising for lost animals and runaway wives. Fifty years later (1759) Dr. Johnson thought that "the trade of advertising is now so near to perfection that it is not easy to propose any improvement." The first newspaper advertisement in America appears in the Boston 'News-Letter,' of 1704. Notices of shipping and rewards for slaves were numerous in the 'New England Weekly Journal' (Boston) of 1728, and shortly after this American newspapers began to carry miscellaneous trade advertisements.

In Great Britain advertisements were heavily taxed until 1833, an impost of 3s. 6d. being levied on each one appearing in a newspaper, though it might be but a laborer's advertisement for work. Upon the abolition of this tax advertising immediately began to grow. To-day Great Britain probably stands next to the United States in the extent of its advertising expenditure. The London and provincial newspapers are heavily patronized, while outdoor advertising is more extensive and less sightly than in this country. English magazines, though numerous, have never been developed as advertising mediums to the extent that the American have. In advertising practise British tradesmen and manufacturers respect and study American advertising methods, adapting many of our devices to their own needs. In Continental Europe advertising finds its chief outlet in the newspapers, which often have tremendous circulations, and by means of outdoor posters and bulletins. The latter forms of advertisement are generally controlled by governments on the Continent, and not only yield a revenue to the State, but are regulated as to size, location and display. While France, Germany, Italy and other countries have numerous weekly and monthly reviews, none of them have ever attained the importance of leading American magazines as advertising mediums. Great Britain and the continental countries have better facilities for the transportation of merchandise parcels through the posts, and it might be thought that on this account some system corresponding to our mail order advertising would have been developed. But mail order advertising is limited there, probably because most of the population is in close touch with distributing centers, and also because the mass of the people not so evenly prosperous as American farmers, have a smaller purchasing power.

The real development of advertising as a factor in the distribution of commodities may be said to have begun only with the appearance of the steamboat and railroad, the modern postal system and the telegraph. Its rapid growth since then, especially in the United States, where the great distances between producer and consumer lessen direct dealing, would seem to indicate that it is a legitimate wheel in distributive machinery rather than a form of aggrandized puffery. In this sense, advertising is but little more than 50 years old. Before then, it had chiefly a curious interest. A full and entertaining description of early advertising will be found in Sampson's 'History of Advertising from the Earliest Times' (London 1874).

Development of Advertising.—Advertising in the modern sense was first sparingly employed by retail merchants in large cities. About 1840 improved postal facilities in the United States broadened newspaper circulation and brought into being the earliest trade, denominational, agricultural and general periodicals of national circulation. These made it profitable to advertise over wide territory. Soon there were firms, chiefly patent nostrum makers, whose chief expenditure was for advertising, and the value of the new force was appreciated by charlatans, quacks and swindlers to such an extent that the public soon learned to distrust advertising. For more than a generation it was not considered reputable by the great majority of legitimate business houses. The power of advertising as a force in merchandising, however, eventually brought reputable interests into the field. The swindler began to retreat. Among the first classes of manufacturers to advertise widely were makers of novel commodities, such as sewing machines, typewriters, bicycles, baking powders, infant foods, etc., then quite new for the most part. In the period from 1880 to 1890 the charlatan was practically forced out of American advertising mediums as legitimate business increased in them, and in the period from 1890 to 1905, with public confidence gained, the growth of both advertising and publications in the United States has been so great that publishing and printing now rank seventh in the country's industries, being exceeded only by iron and steel, slaughtering, foundries and machinery, lumbering, milling and men's clothing. Where formerly the novelties of commerce were advertised, it is now the staples that predominate, such as shoes, flour, cereal foods, clothing, vehicles, etc. The advertising revenue of leading publications is to-day so important that most publishers censor advertising, and investigate a doubtful advertiser before his announcement is inserted. The practise of the publisher making good to readers any loss they may incur through a swindling advertisement is becoming common in this country, and few losses occur. Moreover, the Government has thrown safeguards around advertising, and through the Postoffice effectually prevents swindling operations by denying the use of the mails to an advertiser whose methods will not bear investigation. Advertising has had an immense influence upon the lives of the people, for it not only increases the standard of living and health by introduction of modern conveniences such as baths and sanitary appliances, heating and lighting apparatus, the spread of means of culture, the encouragement of travel, etc., but also tends to improve the quality of commodities without a corresponding increase in cost. Competition in advertising takes the form of price rivalry much more rarely than might be presumed. Advertisers seeking to create national demand for commodities sold under their trade-brands, compete rather in offering excellent staples, assuring purity and marketing in sanitary packages. Advertising has resulted in the invention and use of dust, germ and air-proof cartons, boxes and containers. Formerly it was a kind of puffery, but at present the widest advertising is characterized by the completeness with which it presents information, and the logical reasoning by which it seeks to persuade readers. In the decade from 1895 to 1905 advertising in the United States has outgrown that of every other nation in volume, and has also been conspicuous for its division into special channels, following

the lines of the various periodicals and conditions of demand for commodities.

Retail Advertising embraces the announcements of merchants, large and small, in their own communities, from the full page in each day's newspapers employed by great department stores to the small announcements once or twice a week of the minor shopkeeper. This form of advertising is really a species of news, prepared daily, and is of such interest to the public that many readers take newspapers for their store advertisements, and the journals which carry most of these have the largest circulations. Merchants also publish store news by means of circulars through the mails, minor local journals, programmes, bulletins, posters, etc.

General Advertising is the general term describing exploitation intended to reach the public nationally, or in a group of states. It is found chiefly in magazines and reviews, and in daily newspapers. Street cars, billboards and bulletins are employed as accessories. General advertisers include large manufacturers of food articles, soaps, musical instruments, clothing, beverages, tobacco, household and office supplies, furniture, plate, jewelry, sanitary appliances, etc., as well as the great insurance, steamship and railroad companies, cities and villages seeking population, banks and trust companies, and so forth. This is easily the largest branch of advertising, and the one most influential in distribution. It acts as a stimulus to the local merchant's efforts, and is so wide in scope as to touch every class and interest of the nation, however remote.

Mail Order Advertising is the term applied to a form of exploitation peculiarly American. When the newer communities of the West were insufficiently supplied by their local merchants, several intelligent merchants in Chicago, a city situated geographically for this form of trade, began to advertise commodities to be forwarded direct to consumers by freight and express, receiving orders and remittances through the mails. This was the beginning of "mail order" advertising. Several of these merchants have built up businesses with a gross annual income of $25,000,000 or more, selling practically everything in the way of supplies, machinery, food, clothing, etc., direct to the consumer. Thousands of small advertisers operate with a few commodities through the mails, and many local merchants conduct mail order departments. Mail order advertising is found in the magazines, the farm and religious press, the newspapers, and in a class of cheaply printed periodicals known as "mail order journals," having enormous circulations among people on farms and in villages who are not reached by more costly magazines or daily papers. A large volume of mail order advertising is also done through catalogues and printed matter sent through the mails.

Agricultural Advertising is a form of publicity similar to mail order advertising, but which appears chiefly in farm periodicals and exploits machinery, fertilizers, farm animals, stock food, building materials and farm supplies.

Trade Journal Advertising appears in the numerous special publications devoted to manufacturing, retail and wholesale, commerce, finance, medicine and the professions, mining, transportation, etc. Its object is to acquaint local merchants with commodities manufacturers wish to distribute, to inform engineers and superintendents of manufacturing plants about new machinery, and, generally, to maintain that great organization which produces and handles commodities up to the point where they pass into the consumer's hands.

Advertising Mediums.— In the United States advertising may be divided roughly into four groups, represented by the mediums used: Periodical advertising, outdoor advertising, street-car advertising and mail advertising.

Periodical Advertising includes newspapers, magazines, reviews, trade, denominational and farm publications, periodicals printed in foreign languages, theatre and concert programs and other publications, of which there are not less than 23,000 of all kinds. In 1900 the output of printing and publishing in this country was valued at $350,000,000, of which, it is estimated, fully $200,000,000 represented revenue from advertisements in periodicals and the printing of advertising matter. This item of expenditure is increasing so rapidly that it was estimated at $275,000,000 for 1905. Advertising in periodicals exceeds receipts from subscriptions by $30,000,000. During the 20 years from 1880 to 1900 the increase in advertising receipts of American periodicals was over 40 per cent. In the four States that publish the greatest number of periodicals — New York, Pennsylvania, Massachusetts and Illinois — the receipts from advertising in 1900 were over $52,000,000. The advertising revenue of some of our largest newspapers runs into millions of dollars yearly. Magazines have shown the greatest growth in numbers, circulation and advertising patronage the past decade. In November, 1904, 31 leading monthly magazines in the United States published a total of 3,128 pages of advertising, representing, at an average of $21 an inch, an income of more than $1,000,000 per month from this source. More than 7,500 separate advertisements were represented, and 2,000 separate business houses, with an average expenditure of $500 each for the month, or $6,000 per year. It is held to be a safe rule to spend 5 per cent of the selling price of a commodity in advertising, so that this advertising for a single month in 31 publications would have to return a gross amount exceeding $20,000,000 to be profitable, or nearly $250,000,000 yearly. While the largest newspaper circulations seldom exceed 300,000 copies, daily, the circulation of several monthly magazines is more than 1,000,000 copies per issue, and of one weekly more than 800,000 copies per issue.

Outdoor Advertising includes posters and placards pasted on billboards and barns, painted signs on barns, fences and walls, as well as specially constructed bulletin boards in large cities which are electrically illuminated at night, the erection of advertisements about buildings in process of construction, the use of advertising along railroad lines and at populous seaside resorts, etc. As much as $10 per square foot has been paid for the privilege of advertising on a wall in New York City. Electric signs, with advertisements outlined in incandescent lamps, are an important form of expenditure for outdoor advertising. The largest advertisement of this sort in the world is a single word on a New York building, with letters 60 feet high, visible to 50,000,000 passengers on ferries each year. Advertising of this character adds to the attractiveness of a city by its diffusion of light

through the main streets at no cost to the public. Billboards and other outdoor advertising are more often charged with abuses and unsightliness than any other form, and in some cities are prohibited in the vicinity of parks by municipal regulation. They have never come under control to the extent common on the Continent, and in comparison with the outdoor advertisements of London are perhaps pleasing. Outdoor advertising is thought to be effective in reaching persons not habitual readers of newspapers, as well as to lay emphasis upon newspaper and magazine advertising by repeating the names of commodities more fully described in the press. It necessarily affords no opportunities for description of articles, but is confined to repetition of brands and trademarks.

Street Car Advertising is a medium that has become prominent in the United States since the introduction of electric traction and the spread of trolley lines through cities and suburbs. An enormous population is carried in these vehicles — more than 5,000,000,000 cash fares are paid on trolleys yearly, and perhaps two-thirds of these represent an extra ride in the shape of a transfer. It is possible to maintain an advertising card in the 32,000 cars throughout the United States, covering about 400 towns and cities, for $150,000 a year, and in point of the number of persons who can be reached for a given sum the trolley, elevated and subway lines are said to offer the cheapest form of advertising. Car advertising in New York City, it is claimed, has a national circulation owing to the fact that 250,000 persons from all over the country are constantly in the metropolis. More matters may be printed on a car card than on an outdoor poster, and while there are few instances where large advertisers have attained success through the use of billboards alone, quite a number have confined their operations to street cars with profit. As a rule, though, advertising aims toward a balanced effect in magazines, newspapers, cars, billboards and printed matter.

Mail Advertising.— In 1679 a London haberdasher gave to each customer who purchased goods to the value of a guinea a printed list of his stock, and this was regarded as a dangerous innovation because, if followed generally, it would result in the investment of too much tradesmen's capital in printed bills. From this humble beginning the use of circulars and catalogues has grown to a point where, at present, in the United States, every second letter carried through the mails is an advertising letter, and for every periodical posted there is mailed a catalogue or brochure. Postage on advertising matter aggregated between $25,000,000 and $30,000,000 in 1904, and this perhaps represented only one-tenth the cost of compiling and printing such advertising. Mail advertising takes many forms, from the leather-bound catalogue of 500 or more pages to the humble postal card. Every general advertiser has descriptive matter in booklet form which is mailed freely to those who express interest in his magazine or newspaper advertising, and in many instances the periodicals are used only to excite such interest, printed matter being relied upon to tell the whole story of such complicated apparatus as an agricultural implement, heating furnace or piano-player. Many advertising letters are sent out to lists of persons who may be interested in certain commodities, either printed in imitation of typewriting or actually written on a typing machine. Mail advertising also embraces the distribution at regular postal rates of small periodicals devoted to the interests of a manufacturing or merchandising house. There are hundreds of these personal business organs, some of which have been of sufficient interest to enlarge into standard magazines. Mail advertising also includes the distribution of what are known as "advertising novelties," ingenious or useful trifles ranging from puzzles to match-boxes, and comic cards to desk calendars, all bearing the name of an advertiser. Blotters, calendars, almanacs, reproductions of paintings and many other forms of printed advertising, upon tin, cardboard, paper, wood, leather, cloth, bark, porcelain, glass and other substances travel through the mails. This is the most costly form of advertising known, in proportion to the number of persons that can be reached for a given expenditure, but as most of this matter is sent to persons thought to be directly interested, it often pays a larger return than advertising distributed promiscuously through periodicals, etc.

Advertising Agencies.— Soon after advertising began to be used nationally instead of locally it was found convenient to put details of corresponding with newspapers, arranging rates, writing the advertisements, seeing that they were properly inserted, etc., into the hands of a new functionary who then sprang up — the Advertising Agent. The first advertising agent to open an office for the reception of advertisements in this country was Volney B. Palmer. He began business in Philadelphia in 1840, and subsequently established offices in Boston and Baltimore as well. Before this, however, the advertising agent was known abroad, for Balzac mentions ("Le Deputé d'Arcis") as among the tenants of a Paris rookery in the thirties, "women of the town, still-born insurance companies, newspapers fated to die young, impossible railway companies, discount brokers and advertisement agents who lack the publicity they profess to sell — in short, all description of shy or doubtful enterprise." When national advertising was new there existed no newspaper directories. To advertise in a given territory it was necessary to go to an advertising agent who had lists of the newspapers and knew their rates. Agents often purchased several columns of space in a number of newspapers by the year, re-selling allotments to advertisers for a price less than the newspaper would charge direct. The advertising agent was thus a broker, and to encourage him in developing advertising the newspapers paid him a commission on what he sent in. Then, as demand grew, he became also an adviser to new advertisers, giving counsel as to the ways in which a given appropriation should be spent, preparing the text and illustrations and supplementary matter to be used, checking insertions in papers and bills, etc. This detail work is complex, and the advertising agent usually performs it more reasonably than an advertiser could do himself. From a broker in space, the advertising agent of the present day has become a specialist whose services are valued because he has a wide experience in directing the operations of many advertisers, as well as an equipment for writing and illustrating advertising matter. While the advertising agent is still

paid by commissions of 10 to 15 per cent allowed him by publishers of newspapers and magazines, he is in no sense the agent of the publishers, but receives rather a wholesale rate upon advertising space, which he sells to the advertiser at a retail or gross price. An advertising agent's interests are so wholly bound up with his advertising client's that in some instances he receives for his services a salary besides. Advertising agents have been of the utmost importance in the development of advertising, for by active work in leading conservative business houses to utilize this modern distributive force, they have built up the revenues of publishers, improved publications and driven advertising charlatans from the field. A few of the largest advertisers maintain departments in their business to prepare and supervise their own advertising, while publishers of magazines and newspapers also carry on independently the work of converting business houses to advertising. Despite this, the agent's function has remained an indispensable one, and with the development of advertising he has entrenched it by specializing. One of the leading New York advertising agencies, for example, has been instrumental in building up the large showing of steamship, railroad and travel advertising now carried in leading magazines, with supplementary advertising of hotels and resorts. Two other agencies are known for their work among advertisers of agricultural implements, another has found its field in the development of textile advertising through magazine and trade journal advertising, etc.

With the past decade the advertising agent has ceased to be what the name would imply and has really become a professional man whose advice is sought as such by the largest commercial and financial concerns. The leaders in this new profession have become experts on trade conditions, and in the introduction of new goods or the development of trade in well-established lines. The modern well-equipped advertising agency has attached to it not only competent writers of advertisments, artists and photographers, but experts in salesmanship who study economic questions and conditions with the greatest thoroughness. This branch of the work has been carried by some of the leading agencies to the point of becoming advisors and lecturers to the regularly employed traveling men of the concerns represented.

Special Advertising Agencies differ from the foregoing *general* advertising agencies in that they actually represent the publishers of certain newspapers or miscellaneous journals in a given territory, promoting advertising only for those journals and receiving commissions on all business that comes from such territory. These special agents are found chiefly in New York and Chicago, where a large percentage of advertising originates, and are simply branch offices of publishers outside such cities, who take such means for being represented. In several States associations have been formed among the smaller daily papers who unite in employing a representative who acts as their agent in procuring business.

As advertising has developed in this country it seeks ever new, varied channels, so that while it is possible by a proper selection of mediums to reach practically the whole public, it is also possible, on the other hand, to appeal to a small group of persons interested in some special commodity. No adequate outline of the many forms of advertising could be given in an article of this scope, and readers interested in a fuller presentation of methods, cost, the stories of famous advertisers, etc., are referred to 'History of Advertising' (London, 1874); 'Modern Advertising' (New York, 1905); 'The Theory of Advertising' (Boston, 1904); 'Forty Years an Advertising Agent' (New York, 1906); 'Principles of the Mail Order Business' (Chicago, 1903); 'The Business of Advertising' (London, 1905). In addition to the above there are numerous newspaper directories published annually.

American advertising has a large periodical literature of its own, comprising fully 25 weekly and monthly journals. Many of these are illustrated and assume the dignity in matter and typography of the standard magazine. Among the most notable of these publications are 'Printers' Ink' (weekly, New York); 'Profitable Advertising' (monthly, Boston); 'Fame' (monthly, New York); 'Agricultural Advertising' (monthly, Chicago); 'Mail Order Journal' (monthly, Chicago); 'Judicious Advertising' (monthly, Chicago); 'Ad Sense' (monthly, Chicago), and others. FRANK PRESBREY.

The Frank Presbrey Co., New York.

Advocate, (1) Originally one whose aid was called in or invoked; one who helped in any business matter; (2) in law, at first, one who gave his legal aid in a case, without, however, pleading, this being the function of the *patronus;* (3) the *advocatus fisci,* who attended to the interests of the *fiscus,* or the emperor's privy purse.

In the old German empire, a person appointed by the emperor to do justice. In Germany and elsewhere juridical advocates were made judges in consequence of their attending when causes were pleaded in the count's court.

In the mediæval church, one appointed to defend the rights and revenues of a church or monastery. The word advocate, in the sense of a defender of the Church, was ultimately superseded by that of patron, but it still lingers in the term advowson.

Constitutional advocates, in Rome, pleaded before the consistory in cases relating to the disposal of benefices which they opposed. Elective advocates were chosen by a bishop, an abbot, or a chapter. Feudal advocates were persons assigned lands on condition of their fighting for the Church, leading out their vassals for the purpose. Matricular advocates defended the cathedral churches. Military advocates were appointed to fight for the Church. The Devil's advocate is a Roman ecclesiastic whose office it is to urge whatever objections may exist to the canonization of any proposed saint.

In English law, originally one who pleaded a cause in a civil, but not in a criminal, court; alone entitled to plead as counsel in ecclesiastical and admiralty courts, which are now thrown open to the ordinary bar. Now, in English and American law, one who pleads a cause in any court. It is not properly speaking, a technical word, but is used only in a popular sense, while the attorney and barrister (q.v.) have defined special attributes.

Æe'tes. See ARGONAUTS.

Æga'dian Islands, a group lying off the W. extremity of Sicily, and consisting of Maritimo, Favignana, Levanso, and Le Formiche. Favignana, the largest, is about 14 m. in circuit, and has productive tunny and anchovy fisheries. The group has a population of 6,300. Near these islands the Romans won a great naval battle with the Carthaginians, 741 B.C., which ended the first Punic war.

Ægean Sea, ē-jē'an or ī'gā-an, the old name of the gulf between Asia Minor and Greece, now usually called the Grecian Archipelago (q.v.).

Ægeus, ē'jūs. See THESEUS.

Ægi'na, a Greek island about 15 m. S.W. of Athens, in the Gulf of Ægina (old Sinus Saronicus); area, 32 sq. m.; pop. about 7,000. It is the triangular top of a partly submerged rocky hill, with deep gorges and ravines, and the eastern half rocky and unproductive; but the western is a well-cultivated plain, which under the warm air and sea produce the best Greek almonds, with olives and other fruits, wine, and some grain. The non-agricultural inhabitants do a considerable commerce and navigation from the one port, the capital, Ægina (pop. about 5,000), at the northwest, on the site of the old Greek town, of which considerable remains are left, the ruins of solidly built walls and harbor moles still attesting its ancient size and importance. According to the legend, the island was named after the nymph Ægina, brought thither by Zeus. Historically, its first inhabitants were Achæans, and were expelled by a Dorian colony from Epidaurus, under whom it was one of the foremost commercial cities of Greece, full of hardy, energetic people, born seamen, who covered themselves with glory at Salamis. They were later forced to become a tributary part of the Athenian empire, and in 431 B.C. were expelled altogether. Lysander afterward restored them, but the city's old importance was gone. On a hill in the northeast are the remains of a splendid temple of Zeus Panhellenius (or, as others maintain, of Athena), many of the columns of which are still standing. Here were found in the early 19th century a number of marble statues which once adorned the east and west fronts of the temple; they were purchased by the king of Bavaria in 1812, the deficient parts restored by Thorwaldsen, and are now among the chief ornaments of the Glyptothek at Munich.

Æg'inhard. See EGINHARD.

Ægir, ā'jir, a Norse god of the sea-storms, who treats the other gods to foaming beer, and has a wife Ran caring for those lost at sea. Their nine daughters are sea-waves, with names representing the aspects of the ocean.

Ægirite, a mineral essentially identical with acmite (q.v.). Like it, ægirite is monoclinic, and is a silicate of sodium and both ferric and ferrous iron, the former largely predominating. It is a member of the pyroxene group and is regarded by Miers as an alkali diopside. It is distinguished from acmite by its simple, prismatic crystals, usually bluntly terminated, its dark green color, and its characteristic grass green, pale green and brown pleochroism. Its hardness is 6 to 6.5 and specific gravity about 3.53. It occurs in long prismatic crystals chiefly in the elæolite-syenites of Norway and Arkansas.

Ægis, e'jis ("storm"), the shield of Zeus, fashioned by Hephæstus (Vulcan). From a probably mistaken etymology it was often said to have been the skin of the goat Amalthea, who suckled Zeus, and to have had the Gorgon's head in the centre. When Zeus was angry he waved and shook the ægis, making a sound like a tempest, by which the nations were overawed. It was the symbol of divine protection, and became in course of time the exclusive attribute of Zeus and Athene.

Ægis'thus, ē-jis'thŭs, son of Thyestes, and cousin of Agamemnon; adopted son of Atreus (q.v.). He did not accompany the Greeks to Troy, and during Agamemnon's absence lived in adultery with his wife Clytemnestra. He assisted her in murdering her husband on his return, but was himself put to death seven years later by Orestes, son of Agamemnon. This is the account given by Homer; the tragic poets make Clytemnestra alone murder Agamemnon, her motive in Æschylus being her jealousy and wrath at the death of Iphigenia of Cassandra; in Sophocles and Euripides, the latter alone. Later writers also describe Ægisthus as the son of Thyestes by unwitting incest with his daughter Pelopia. See AGAMEMNON; ATREUS.

Ægium, ē'jĭ-um, Greece, modern VASTITZA, though officially restored to its ancient name. See ACHAIA.

Ægle, a genus of plants of the natural order *Aurantiaceæ*. The *Ægle marmelos* is the tree which produces the bhel fruit. This fruit is most delicious to the taste, being exquisitely fragrant and nutritious, but laxative. When a little unripe it has been long used in India with great effect as an astringent in cases of diarrhœa and dysentery.

Ægospot'amos or **Ægospot'amoi** ("goat-river"), the Thracian Chersonesus (now peninsula of Gallipoli): a river and town memorable for the battle, or rather surprise, in which the Spartan general Lysander annihilated the Athenian fleet, 13 Dec. B.C. 405, and ended the Peloponnesian war by the temporary ruin of Athens. The latter had 180 vessels, with a number of coequal commanders, only one of whom (Conon) had common military sense, and perhaps treachery was at work; while Lysander was an eminent military genius and had no one to consult but himself. Having put them off their guard by ostentatious carelessness and absence for several days, he swooped down upon them one day at dinner-time while their ships were totally unprepared (despite the warnings of Alcibiades, whose castle was close by and who was fully a match for Lysander), and destroyed or captured the entire fleet except Conon's small squadron. Athens fell under the rule of Sparta, which set up an aristocratic government, the outcome of which is infamous in history as the Thirty Tyrants.

Ægyp'tus, in Greek legend, son of Belus, king of Arabia; conquered the land called Egypt from him. He gave his fifty sons in marriage to the fifty daughters of his brother Danaus, who had established himself in Argos and was jealous of his brother, and who obliged all his daughters to murder their husbands on the night

of their nuptials: Hypermnestra alone spared her husband, Lynceus. Even Ægyptus was killed by his niece Polyxena. See DANAUS; EGYPT.

Ælfric, āl'fric, the **Grammarian**, Anglo-Saxon author and translator; fl. 1006. In his youth he was taught by a secular priest who could scarcely understand Latin. "There was no one," he says, "who could write or understand Latin letters until Dunstan and Æthelwold revived learning." This may account for his warm interest in education and his industry in translation and compilation. 'A Treatise on the Old and New Testaments' (printed 1623); the 'Heptateuchus,' an abridgment and translation of the first seven books of the Old Testament, with the Book of Job (pr. 1699); a 'Pastoral Letter,' written for Wulfstan, archbishop of York (1003-23), in which he makes the archbishop declare that he will not forcibly compel his clergy to chastity, but admonishes them to observe it; a 'Latin Grammar and Glossary' (printed by Somner, 1659).

Ælia, a Roman *gens*, whose members included Sejanus, Hadrian, and the Antonines, as also the families of Pætus (q.v.), Gallus, etc.

Ælia Capitolina, the new name given to Jerusalem by Hadrian when he colonized it with Romans after the insurrection of 132-5 A.D.; he built a temple to Jupiter Capitolinus, and prefixed the name of his own *gens*, the Ælian. The Christian emperors after Constantine restored the old name.

Ælianus, Claudius, ē-li-ā'nus, a noted Roman sophist who flourished in the first half of the 2d century: b. Præneste, Italy. Of his many works, written in Greek, two are extant: 'Various Histories,' or narratives, in 14 books, and 'Of the Nature of Animals,' anecdotes of animals,— most entertaining and uncritical compilations. The 'Peasants' Letters' accredited to him are spurious. Best ed., Hercher, 1858 and 1864.

Æmilia'nus, C. Julius, emperor of Rome: a Moor who rose from the lowest stations; governor of Pannonia and Mœsia, whose troops killed the Emperor Gallus and gave him the crown. He reigned only four months, when he was killed in his 46th year by his own soldiers, who then offered the crown to Valerian.

Æmilian Way, a Roman state road about 185 m. long, built by the consul Marcus Æmilius Lepidus, 187 B.C., primarily as a military road to make easy communication between Rome and her new possessions in Cisalpine Gaul (Lombardy). Beginning at Ariminum (Rimini) on the Adriatic, where the Flaminian way from Rome ended, it traversed Bononia (Bologna), Mutina (Modena), and Parma, crossed the Padus (Po) at Placentia (Piacenza), and ended at Mediolanum (Milan).

Æmil'ius Paulus, surnamed *Macedonicus*, a noble Roman of the ancient family of Æmilii: b. 230 B.C.; d. 160. He conquered Perseus, king of Macedon, and on this occasion obtained a triumph, 168 B.C. During the triumph two of his sons died. He bore the loss like a hero, and thanked the gods that they had chosen them for victims to avert bad fortune from the Roman people. He was father of the renowned Scipio Africanus the Younger.

Æne'as, in the Iliad, a Trojan prince, son of Anchises and the goddess Venus; second only to his kinsman Hector among the Trojan chiefs. Other stories tell that the care of his infancy was entrusted to a nymph; but at the age of five he was recalled to Troy and placed under the inspection of Alcathoüs, his father's friend and companion. He afterward improved himself in Thessaly under Chiron the Centaur, whose house was frequented by all the young princes and heroes of the age. Soon after his return home he married Creusa, Priam's daughter, by whom he had a son called Ascanius. Vergil, whose object is to connect him (according to Latin tradition of untraceable source) with the origin of Rome, tells his further story as follows in the Æneid. In the night of the capture of Troy by the Greeks, Hector warned him in a dream to fly. Æneas notwithstanding rushed to the fight; but after Priam was slain returned to his home and carried off his father, his child, and his household gods, losing, however, his wife, Creusa, in the confusion. With twenty vessels he sailed for Thrace, where he began to build Ænos, but terrified by a miracle abandoned the attempt. Thence he went to Delos to consult the oracle. Misunderstanding its reply he went to Crete, from which he was driven by a pestilence; thence to the promontory of Actium, and in Epirus found Helenus and Andromache; thence past Italy and through the Straits of Messina, and circumnavigated Sicily to Cape Drepanum on the western coast, where Anchises died. A tempest drove him on the shore of Africa, where Dido received him kindly in Carthage and wished to detain and marry him. Jupiter, however, mindful of the Fates, sent Mercury to Æneas and commanded him to sail for Italy. While the deserted Dido ended her life on the funeral pile, Æneas set sail with his companions and was cast by a storm on the shores of Sicily, in the dominions of his Trojan friend Acestes, where the wives of his companions, wearied of a seafaring and homeless life, set fire to the ships. Nevertheless, after building the city Acesta, he sailed for Italy, leaving the women and the sick behind. He found near Cumæ a sibyl his father's ghost had ordered him to seek, who foretold his destiny and aided his descent into the lower world: here he saw his father and had a prophetic vision of the glorious destinies of his race. On his return he embarked again and reached the eastern shore of the river Tiber, in the country of Latinus, king of the Aborigines (q.v.). His daughter Lavinia was destined by an oracle to a stranger, but promised by her mother Amata to Turnus, king of the Rutuli. This occasioned a war, after the termination of which, Turnus having fallen by his hand, Æneas married Lavinia. His son by Lavinia, Æneas Sylvius, was the ancestor of the kings of Alba Longa, and of Romulus and Remus, the founders of the city of Rome. From Ascanius' son Iulus the Romans derive the Julian family. For the real origin of Rome, see that title.

Æneas Silvius. See PIUS II.

Æne'id, one of the great epic poems of the world; written in Latin by Vergil and published after his death, which took place about 16 B.C. Being left imperfect, his friends Varius and Tucca edited it at Augustus' request. For its story, see ÆNEAS. See also VERGIL.

Æneside'mus, Greek philosopher, fl. 80–60 B.C.: b. Cnossus in Crete, removed to Alexandria. He was a leader of the Skeptical school, and is famous for the "Ten Tropes" attributed to him,— arguments to prove the impossibility of absolute knowledge, and reducible in essence to two, that no two things are alike and everything is relative. They are: (1) That each sentient being must have a different perception and conception of the universe from every other because differently constituted; (2) that human beings differ; (3) that sense organs differ; (4) that the circumstances of perceptions differ; (5) that objects perceived differ in location and distance; (6) that different objects are confounded; (7) that different combinations make the same sensation seem different; (8) that all knowledge is relative; (9) that degrees of familiarity cause differences in perception; (10) that the intellectual speculations, moral theories, laws, manners and customs, civilizations, etc., of all races differ (Locke's argument against intuitive ideas).

Ænianes, ē-nī'a-nēs, in classic Greek, an Achæan people living on the southern border of Thessaly, in the mountains west of Thermopylæ; members of the Ætolian League and the Delphic Amphictyony.

Æo'lian, a musical instrument. See MUSICAL INSTRUMENTS, MECHANICAL.

Æolian Harp, or **Æolus' Harp,** is generally a simple box of thin fibrous wood to which are attached a number of fine strings, sometimes as many as fifteen, stretched on low bridges at each end, and carefully tuned so as to be in harmony. Its length is made to correspond to the size of the window or other aperture in which it is intended to be placed. Its width is about five or six inches, its depth two or three. It must be placed with the strings uppermost, under which is a circular opening in the centre, as in the belly of the guitar. When the wind blows athwart the strings it produces the effect of a choir of music in the air, sweetly mingling all the harmonic notes, and swelling or diminishing the sounds according to the strength or weakness of the blast. A simpler kind of Æolian harp has no sounding-board, but consists merely of a number of strings extended between two boards.

Æolians ("variegated," mixed race), an ancient Greek people, perhaps the very earliest Greek stock — a mixture of Hellenes and Pelasgi — before the special races like Ionians and Dorians had differentiated from it; as their language was not a distinct dialect like those, but is a mixture of elements from all and presents the closest link of any between Greek and Latin. The Homeric language is Æolic. The race extended from northeast to southwest through Greece, from the Pagasaic Gulf through Thessaly or at least Phthiotis, Bœotia, Phocis, Locris, and Ætolia north of the Corinthian Gulf, to Elis and Messenia south of it. The sons of Æsculapius (q.v.), Philoctetes, Odysseus, Nestor, and the Oïlean Ajax, were Æolians; and legend accredits to the same stock Jason, Melampus the healer who understood the song of birds, Sisyphus the founder of Corinth, and Athamas the great king of the Minyæ, son-in-law of Cadmus and father of Phrixus and Helle. The Achæans, if not originally part of the same stock, became blent with them and are classed by the ancients as part of them; and there is no separate Achæan dialect or art. Probably they were one, and the Peloponnesian Achæi were certainly part of them; and the great emigration commonly called the Æolian was an emigration of Achæan people. It seems probable that the emigration from the Peloponnesus began before the Dorian invasion, or return of the Heraclidæ, as it is often called, which caused so great a revolution in the peninsula. Strabo says the Æolian settlements in Asia were four generations prior to the Ionian. Their colonies on the Asiatic mainland were widely spread, extending at least from Cyzicus, along the shores of the Hellespont and the Ægean, to the river Caicus, and even the Hermus. Many positions in the interior were also occupied by them, as well as the fine island of Lesbos, with Tenedos, and others of smaller importance. Homer mentions all these parts as possessed by a different people; which would be proof, if any were wanting, that the race of new settlers came after his time. There were twelve cities or states included in the older settlments in that tract of Asia Minor on the Ægean which was known in Greek geography by the name of Æolis and formed a part of the subsequent larger division of Mysia. Smyrna, one of them, which early fell into the hands of the Ionians, the neighbors of the Æolians, still exists nearly on the old spot, with exactly the same name; thus adding one to the many instances of the durable impression made by Greek colonies wherever they settled.

Æolis. See ÆOLIANS.

Æ'olus, in Greek legend: (1) Ruler of the winds; a sort of sub-deity, having his residence in a floating island, said to be one of the Æolian Islands, or by the Latin and later Greek poets one of the Lipari Islands. Here he kept the winds in bags (Virgil says in caves), restraining or letting them loose at the orders of Zeus. In the Odyssey he gives them to Odysseus to take care of for a time. (2) The eponymous ancestor of the Æolians, located in Thessaly; Hellen was his father and Dorus his brother (eponyms of the Hellenes and Dorians), and Sisyphus his son, the significance of which is not ascertainable. (1) and (2) may have been originally the same, but if so they arose as independent metaphors or eponyms.

Æqui, an ancient people of Italy, conspicuous in the early wars of Rome. They inhabited the mountain district between the upper valley of the Anio (Teverone) and Lake Fucinus. Their origin is unknown; but they were probably akin to the Volscians, with whom they were in constant alliance. This league after the fall of the monarchy made great headway and captured many towns, their power culminating in the 5th century B.C. At length they were severely defeated by Cincinnatus in 458, and again by the dictator Postumus Tubertus in 428. They were finally subdued about 304, and soon after were admitted to Roman citizenship, being included in the new tribes Aniensis and Terentina. Henceforth their name disappears from history; but the inhabitants of the upper valleys began to be called Æquiculi, by which name they are mentioned by Vergil as predatory mountaineers. The name Æquiculani occurs in Pliny.

Ærarium, e-rā'ri-um ("money-place"), the public treasury of ancient Rome; containing not only the state moneys and accounts, but the legionary standards, the public laws (on brass plates), senate decrees, and other important papers and registers. It was located in the temple of Saturn, on the eastern slope of the Capitoline hill. Besides the general treasury, filled from general taxes and drawn on for regular expenses, there was in the same building, a "sacred treasury," or reserve fund, replenished chiefly by a 5 per cent tax on the value of manumitted slaves, which was never drawn upon except on occasions of extreme necessity. The senate controlled the ærarium nominally even under the early emperors, who had their separate imperial treasury called the *fiscus;* but as the senate became a mere name, the figment of two treasuries was gradually abolished. Augustus established also a military treasury devoted solely to army accounts. The later emperors had likewise a private treasury, aside from the general one which they administered for the empire.

Aërated Bread. See BREAD.

Aërated Waters. See MINERAL WATERS.

Aërial Conveyer. See CONVEYER.

Aërial Locomotion. We are all of us interested in aërial locomotion; and I am sure that no one who has observed with attention the flight of birds can doubt for one moment the possibility of aërial flight by bodies specifically heavier than the air. In the words of an old writer, "We cannot consider as impossible that which has already been accomplished."

I have had the feeling that a properly constructed flying-machine should be capable of being flown as a kite; and, conversely, that a properly constructed kite should be capable of use as a flying-machine when driven by its own propellers. I am not so sure, however, of the truth of the former proposition as I am of the latter. Given a kite, so shaped as to be suitable for the body of a flying-machine, and so efficient that it will fly well in a good breeze (say 20 miles an hour) when loaded with a weight equivalent to that of a man and engine; then it seems to me that this same kite, provided with an actual engine and man in place of the load, and driven by its own propellers at the rate of 20 miles an hour, should be sustained in calm air as a flying-machine. So far as the pressure of the air is concerned, it is surely immaterial whether the air moves against the kite, or the kite against the air.

Of course in other respects the two cases are not identical. A kite sustained by a 20-mile breeze possesses no momentum, or rather its momentum is equal to zero, because it is stationary in the air and has no motion proper of its own; but the momentum of a heavy body propelled at 20 miles an hour through still air is very considerable. Momentum certainly aids flight, and it may even be a source of support against gravity quite independently of the pressure of the air. It is perfectly possible, therefore, that an apparatus may prove to be efficient as a flying-machine which cannot be flown as a kite on account of the absence of *vis viva*. However this may be, the applicability of kite experiments to the flying-machine problem has for a long time past been the guiding thought in my researches.

I have not cared to ascertain how high a kite may be flown or to make one fly at any very great altitude. The point I have had specially in mind is this: That the equilibrium of the structure in the air should be perfect; that the kite should fly steadily, and not move about from side to side or dive suddenly when struck by a squall, and that when released it should drop slowly and gently to the ground without material oscillation. I have also considered it important that the framework should possess great strength with little weight.

I believe that in the form of structure now attained the properties of strength, lightness, and steady flight have been united in a remarkable degree. In my younger days the word "kite" suggested a structure of wood in the form of a cross covered with paper forming a diamond-shaped surface longer one way than the other, and provided with a long tail composed of a string with numerous pieces of paper tied at intervals upon it. Such a kite is simply a toy. In Europe and America, where kites of this type prevailed, kite-flying was pursued only as an amusement for children, and the improvement of the form of structure was hardly considered a suitable subject of thought for a scientific man. In Asia kite-flying has been for centuries the amusement of adults, and the Chinese, Japanese, and Malays have developed tailless kites very much superior to any form of kite known to us until quite recently. It is only within the last few years that improvements in kite structure have been seriously considered, and the recent developments in the art have been largely due to the efforts of one man — Laurence Hargrave of Australia.

Hargrave realized that the structure best adapted for what is called a "good kite" would also be suitable as the basis for the structure of a flying-machine. His researches, published by the Royal Society of New South Wales, have attracted the attention of the world, and form the starting point for modern researches upon the subject in Europe and America. Anything relating to aërial locomotion has an interest to very many minds, and scientific kite-flying has everywhere been stimulated by Hargrave's experiments.

In America, however, the chief stimulus to scientific kite-flying has been the fact developed by the United States Weather Bureau, that important information could be obtained concerning weather conditions if kites could be constructed capable of lifting meteorological instruments to a great elevation in the free air. Mr. Eddy and others in America have taken the Malay tailless kite as a basis for their experiments, but Prof. Marvin, of the United States Weather Bureau; Mr. Rotch, of the Blue Hill Observatory, and many others have adapted Hargrave's box kite for the purpose. Congress has made appropriations to the Weather Bureau in aid of its kite experiments, and a number of meteorological stations throughout the United States were established a few years ago equipped with the Marvin kite. Continuous meteorological observations at a great elevation have been made at the Blue Hill Observatory in Massachusetts, and Mr. Rotch has demonstrated the possi-

bility of towing kites at sea by means of steam vessels so as to secure a continuous line of observations all the way across the Atlantic.

HARGRAVE'S BOX KITE.

Hargrave introduced what is known as the "cellular construction of kites." He constructed kites composed of many cells, but found no substantial improvement in many cells over two alone; and a kite composed of two rectangular

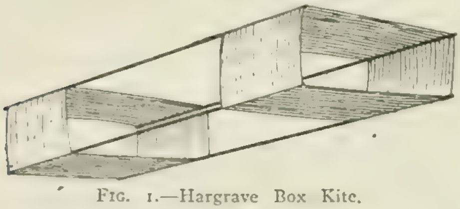

FIG. 1.—Hargrave Box Kite.

cells separated by a considerable space is now universally known as "the Hargrave box kite." This represents, in my opinion, the high-water mark of progress in the 19th century; and this form of kite forms the starting point for my own researches (Fig. 1). The front and rear cells are connected by a framework, so that a considerable space is left between them. This space is an essential feature of the kite: upon it depends the fore and aft stability of the kite. The greater the space, the more stable is the equilibrium of the kite in a fore and aft direction, the more it tends to assume a horizontal position in the air, and the less it tends to dive or pitch like a vessel in a rough sea. Pitching motions or oscillations are almost entirely suppressed when the space between the cells is large. Each cell is provided with vertical sides; and these again seem to be essential elements of the kite contributing to lateral stability. The greater the extent of the vertical sides, the greater is the stability in the lateral direction, and the less tendency has the kite to roll, or move from side to side, or turn over in the air.

In the foregoing drawing I have shown only necessary details of construction, with just sufficient framework to hold the cells together. It is obvious that a kite constructed as shown in Fig. 1 is a very flimsy affair. It requires additions to the framework of various sorts to give it sufficient strength to hold the aëroplane surfaces in their proper relative positions and prevent distortion, or bending or twisting of the kite frame under the action of the wind. Unfortunately the additions required to give rigidity to the framework all detract from the efficiency of the kite: First, by rendering the kite heavier, so that the ratio of weight to surface is increased; and secondly, by increasing the head resistance of the kite. The interior bracing advisable in order to preserve the cells from distortion comes in the way of the wind, thus adding to the ***drift*** of the kite without contributing to the ***lift***.

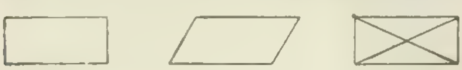

FIG. 2.

A rectangular cell like *A* (Fig. 2) is structurally weak, as can readily be demonstrated by the little force required to distort it into the form shown at *B*. In order to remedy this weakness, internal bracing is advisable of the character shown at *C*. This internal bracing, even if made of the finest wire, so as to be insignificant in weight, all comes in the way of the wind, increasing the head resistance without counterbalancing advantages.

Triangular Cells in Kite Construction.—In looking back over the line of experiments in my own laboratory, I recognize that the adoption of a triangular cell was a step in advance, constituting indeed one of the milestones of progress, one of the points that stand out clearly against the hazy background of multitudinous details. The following (Fig. 3) is a drawing of a typical triangular-celled kite made upon the same general model as the Hargrave box kite shown in Fig. 1. A triangle is by its very structure perfectly braced in its own plane, and in a triangular-celled kite like that shown in Fig. 3, internal bracing of any character is unnecessary

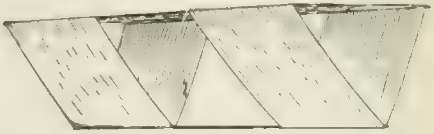

FIG. 3.

to prevent distortion of a kind analogous to that referred to above in the case of the Hargrave rectangular cell (Fig. 2).

The lifting power of such a triangular cell is probably less than that of a rectangular cell, but the enormous gain in structural strength, together with the reduction of head resistance and weight due to the omission of internal bracing, counterbalances any possible deficiency in this respect.

The horizontal surfaces of a kite are those that resist descent under the influence of gravity, and the vertical surfaces prevent it from turning over in the air. Oblique aëroplanes may therefore conveniently be resolved into horizontal and vertical equivalents, that is, into supporting surfaces and steadying surfaces. The oblique aëroplane *A*, for example (Fig. 4), may be considered as equivalent in function to the two aëroplanes *B* and *C*. The material composing the aëroplane *A*, however, weighs less than the material required to form the two aëroplanes

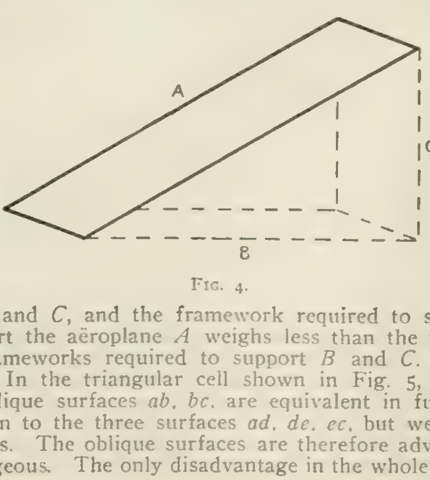

FIG. 4.

B and *C*, and the framework required to support the aëroplane *A* weighs less than the two frameworks required to support *B* and *C*.

In the triangular cell shown in Fig. 5, the oblique surfaces *ab*, *bc*, are equivalent in function to the three surfaces *ad*, *de*, *ec*, but weigh less. The oblique surfaces are therefore advantageous. The only disadvantage in the whole ar

rangement is that the air has not as free access to the upper aëroplane *ac*, in the triangular form of cell as in the quadrangular form, so that the aëroplane *ac* is not as efficient in the former construction as in the latter.

While theoretically the triangular cell is inferior in lifting power to Hargrave's four-sided

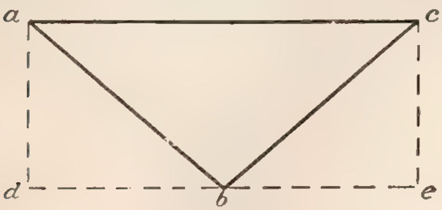

Fig. 5.

rectangular cell, practically there is no substantial difference. So far as I can judge from observation in the field, kites constructed on the same general model as the Hargrave box kite, but with triangular cells instead of quadrangular, seem to fly as well as the ordinary Hargrave form, and at as high an angle. Such kites are therefore superior, for they fly substantially as well, while at the same time they are stronger in construction, lighter in weight, and offer less head resistance to the wind.

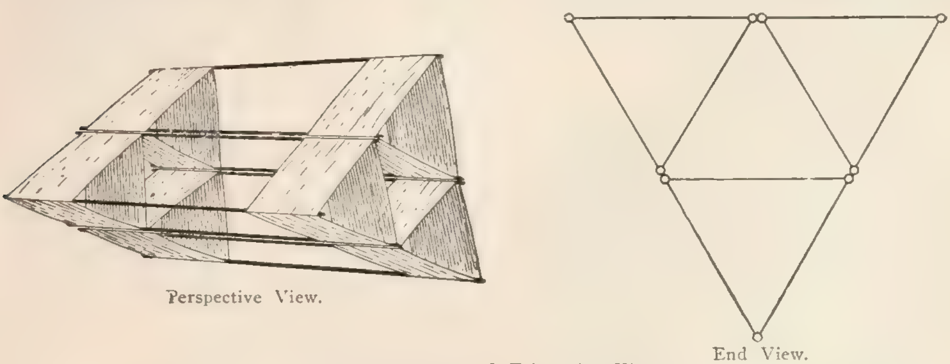

Fig. 6.—Compound Triangular Kite.

Triangular cells also are admirably adapted for combination into a compound structure, in which the aëroplane surfaces do not interfere with one another. For example, three triangular-celled kites, tied together at the corners, form a compound cellular kite (Fig. 6) which flies perfectly well. The weight of the compound kite is the sum of the weights of the three kites of which it is composed, and the total aëroplane surface is the sum of the surfaces of the three kites. The ration of weight to surface therefore is the same in the larger compound kite as in the smaller constituent kites, considered individually.

It is obvious that in compound kites of this character the doubling of the longitudinal sticks where the corners of adjoining kites come together is an unnecessary feature of the combination, for it is easy to construct the compound kite so that one longitudinal stick shall be substituted for the duplicated sticks. For example: The compound kites *A* and *B* (Fig. 7) may be constructed, as shown at *C* and *D*, with advantage, for the weight of the compound kite is thus reduced without loss of structural strength. In this case the weight of the compound kite is less than the sum of the weights

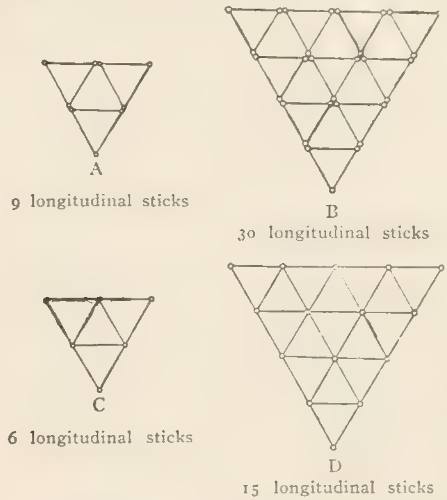

Fig. 7.

of the component kites, while the surface remains the same. If kites could only be successfully compounded in this way indefinitely we would have the curious result that the ratio of weight to surface would diminish with each increase in the size of the compound kite. Unfortunately, however, the conditions of stable flight demand

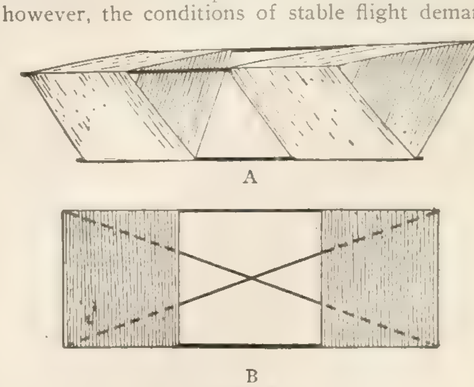

Fig. 8.

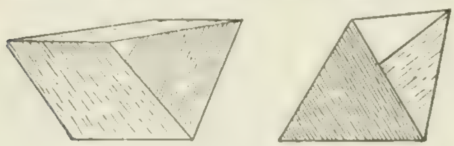
a considerable space between the front and rear sets of cells (see Fig. 6); and if we increase the diameter of our compound structure with-

out increasing the length of this space we injure the flying qualities of our kite. But every increase of this space in the fore and aft direction involves a corresponding increase in the length of the empty framework required to span it, thus adding dead load to the kite and increasing the ratio of weight to surface. While kites with triangular cells are strong in a transverse direction (from side to side), they are structurally weak in the longitudinal direction (fore and aft), for in this direction the kite frames are rectangular. Each side of the kite *A*, for example (Fig. 8), requires diagonal bracing of the character shown at *B* to prevent distortion under the action of the wind. The necessary bracing, however, not being in the way of the wind, does not materially affect the head resistance of the kite, and is only disadvantageous by adding dead load, thus increasing the ratio of weight to surface.

THE TETRAHEDRAL CONSTRUCTION OF KITES.

Passing over in silence multitudinous experiments in kite construction carried on in my Nova Scotia laboratory, I come to another con-

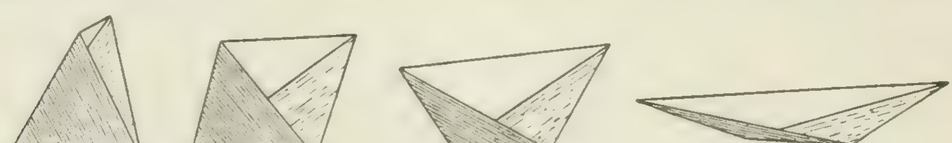


A B

FIG. 9.

A.—A Triangular Cell.
B.—A Winged Tetrahedral Cell.

spicuous point of advance — another milestone of progress — the adoption of the triangular construction *in every direction* (longitudinally as well as transversely); and the clear realization of the fundamental importance of the skeleton of a tetrahedron, especially the regular tetrahedron, as an element of the structure of framework of a kite or flying-machine.



Acute-angled tetrahedron — Regular tetrahedron — Right-angled tetrahedron — Obtuse-angled tetrahedron

FIG. 10.—Winged Tetrahedral Cells.

Consider the case of an ordinary triangular cell *A* (Fig. 9) whose cross-section is triangular laterally, but quadrangular longitudinally. If now we make the longitudinal as well as transverse cross-sections triangular, we arrive at the

FIG. 11.—One-celled Tetrahedral Frame.

form of cell shown at *B*, in which the framework forms the outline of a tetrahedron. In this case the aëroplanes are triangular, and the whole arrangement is strongly suggestive of a pair of birds' wings raised at an angle and connected tip to tip by a cross-bar (see *B*, Fig. 9; also drawings of winged tetrahedral cells in Fig. 10).

A tetrahedron is a form of solid bounded by four triangular surfaces. In the regular tetrahedron the boundaries consist of four equilateral triangles and six equal edges. In the skeleton form the edges alone are represented, and the skeleton of a regular tetrahedron is produced by joining together six equal rods end to end so as

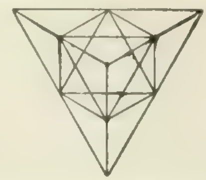


FIG. 12.—Four-celled Tetrahedral Frame.

to form four equilateral triangles. Most of us no doubt are familiar with the common puzzle — how to make four triangles with six matches. Give six matches to a friend and ask him to arrange them so as to form four complete equilateral triangles. The difficulty lies in the unconscious assumption of the experimenter that the four triangles should all be in the same plane. The moment he realizes that they need not be in the same plane the solution of the problem becomes easy. Place three matches on the table so as to form a triangle, and stand the other three up over this like the three legs of a tripod stand. The matches then form the skeleton of a regular tetrahedron. (See Fig. 11.) A framework formed upon this model of six equal rods fastened together at the ends constitutes a tetrahedral cell possessing the qualities of strength and lightness in an extraordinary degree. It is not simply braced in two directions in space like a triangle, but in three directions like a solid. If I may coin a word, it possesses "three-dimensional" strength; not "two-dimensional" strength like a triangle, or "one-dimensional" strength like a rod. It is the skeleton of a solid, not of a surface or a line. It is astonishing how solid such a framework appears even when composed of very light and fragiie material; and compound structures formed by fastening these tetrahedral frames together at the corners so as to form the skeleton of a regular tetrahedron on a larger scale possess equal solidity. Fig. 12 shows a structure composed of four frames like Fig. 11, and Fig. 13 a structure of four frames like Fig. 12.

When a tetrahedral frame is provided with aëro-surfaces of silk or other material suitably arranged, it becomes a tetrahedral kite, or kite having the form of a tetrahedron. The kite shown in Fig. 14 is composed of four winged

cells of the regular tetrahedron variety (see Fig. 10), connected at the corners. Four kites like Fig. 14 are combined in Fig. 15. Upon this mode of construction an empty space of octahedral form is left in the middle of the

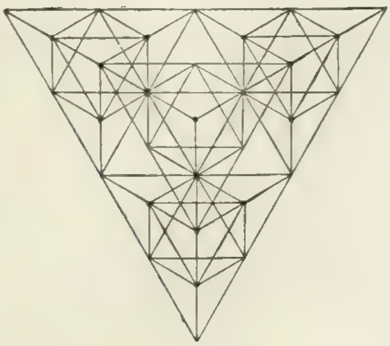

FIG. 13.—Sixteen-celled Tetrahedral Frame.

kite, which seems to have the same function as the space between the two cells of the Hargrave box kite. The tetrahedral kites that have the largest central spaces preserve their equilibrium best in the air.

The most convenient place for the attachment of the flying cord is the extreme point of the bow. If the cord is attached to points successively farther back on the keel, the flying cord makes a greater and greater angle with

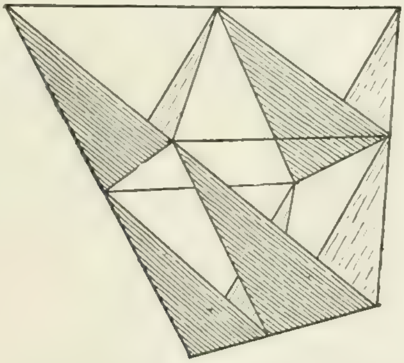

FIG. 14.—Four-celled Tetrahedral Kite.

the horizon, and the kite flies more nearly overhead; but it is not advisable to carry the point of attachment as far back as the middle of the keel. A good place for high flights is a point half way between the bow and the middle of the keel.

In tetrahedral kites the compound structure has itself in each case the form of the regular tetrahedron, and there is no reason why this principle of combination should not be applied indefinitely so as to form still greater combinations.

The weight relatively to the wing-surface remains the same, however large the compound kite may be. The four-celled kite, for example, weighs four times as much as one cell and has four times as much wing-surface, the 16-celled kite has 16 times as much weight and 16 times as much wing-surface, and the 64-celled kite has 64 times as much weight and 64 times as much wing-surface. The ratio of weight to surface therefore is the same for the larger kites as for the smaller.

This at first sight appears to be somewhat inconsistent with certain mathematical conclusions announced by Prof. Simon Newcomb in an article entitled "Is the Air-Ship Coming," published in 'McClure's Magazine' for September 1901 — conclusions which led him to believe that "the construction of an aërial vehicle which could carry even a single man from place to place at pleasure requires the discovery of some new metal or some new force." The process of

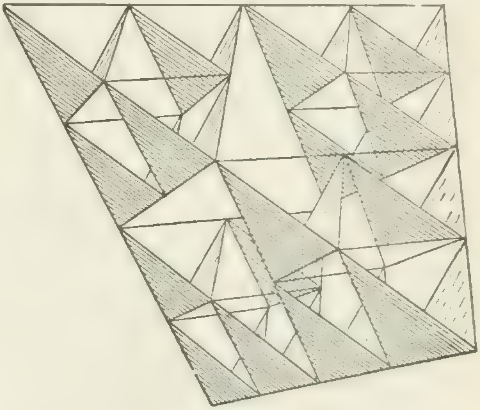

FIG. 15.—Sixteen-celled Tetrahedral Kite.

reasoning by which Prof. Newcomb arrived at this remarkable result is undoubtedly correct. His conclusion, however, is open to question, because he has drawn a general conclusion from restricted premises. He says: "Let us make two flying-machines exactly alike, only make one on double the scale of the other in all its dimensions. We all know that the volume, and therefore the weight, of two similar bodies are proportional to the cubes of their dimensions. The cube of two is eight; hence the large machine will have eight times the weight of the other. But surfaces are as the squares of the dimensions. The square of two is four. The heavier machine will therefore expose only four times the wing surface to the air, and so will have a distinct disadvantage in the ratio of efficiency to weight." Prof. Newcomb shows that where two flying-machines — or kites, for that matter — are exactly alike, only differing in the scale of their dimensions, the ratio of weight to supporting surface is greater in the larger than the smaller, increasing with each increase of dimensions. From which he concludes that if we make our structure large enough it will be too heavy to fly. This is certainly true, so far as it goes, and it accounts for my failure to make a giant kite that should lift a man — upon the model of the Hargrave box kite. When the kite was constructed with two cells, each about the size of a small room, it was found that it would take a hurricane to raise it into the air. The kite proved to be not only incompetent to carry a load equivalent to the weight of a man, but it could not even raise *itself* in an ordinary breeze in which smaller kites upon the same model flew perfectly well. I have no doubt that other investigators also have fallen into the error of sup-

posing that large structures would necessarily be capable of flight, because exact models of them, made upon a smaller scale, have demonstrated their ability to sustain themselves in the air. Prof. Newcomb has certainly conferred a benefit upon investigators by so clearly pointing out the fallacious nature of this assumption.

But Prof. Newcomb's results are probably only true when restricted to his premises. For models exactly alike, only differing in the scale of their dimensions, his conclusions are undoubtedly sound; but where large kites are formed by the multiplication of smaller kites into a cellular structure the results are very different. My own experiments with compound kites composed of triangular cells connected corner to corner have amply demonstrated the fact that the dimensions of such a kite may be increased to a very considerable extent without materially increasing the ratio of weight to supporting surface; and upon the tetrahedral plan the weight relatively to the wing-surface remains the same, however large the compound kite may be.

The indefinite expansion of the triangular construction is limited by the fact that dead weight in the form of empty framework is necessary in the central space between the sets of cells (see Fig. 6), so that the necessary increase of this space when the dimensions of the compound kite are materially increased — in order to preserve the stability of the kite in the air — adds still more dead weight to the larger structures. Upon the tetrahedral plan no necessity exists for empty frameworks in the central spaces, for the mode of construction gives solidity without it. Tetrahedral kites combine in a marked degree the qualities of strength, lightness, and steady flight; but further experiments are required before deciding that this form is the best for a kite, or that winged cells without horizontal aëroplanes constitute the best arrangement of aëro-surfaces. The tetrahedral principle enables us to construct out of light materials solid frameworks of almost any desired form, and the resulting structures are admirably adapted for the support of aëro-surfaces of any desired kind, size, or shape (aëroplanes or aëro-curves, etc., large or small).

In further illustration of the tetrahedral principle as applied to kite construction, I built a kite which is not itself tetrahedral in form, but the framework of which is built up of tetrahedral cells. This kite, although very different in construction and appearance from the Aërodrome of Prof. Langley, which I saw in successful flight over the Potomac a few years ago, has yet a suggestiveness of the Aërodrome about it, and it was indeed Prof. Langley's apparatus that led me to the conception of this form. The wing-surfaces consist of horizontal aëroplanes, with oblique steadying surfaces at the extremities. The body of the machine has the form of a boat, and the superstructure forming the support for the aëroplanes extends across the boat on either side at two points near the bow and stern. The aëroplane surfaces form substantially two pairs of wings, arranged dragon-fly fashion. The whole framework for the boat and wings is formed of tetrahedral cells having the form of the regular tetrahedron, with the exception of the diagonal bracing at the bottom of the superstructure; and the kite turns out to be strong, light, and a steady flyer.

I have flown this kite in a calm by attaching the cord — in this case a Manila rope — to a galloping horse. Upon releasing the rope the kite descended so gently that no damage was done to the apparatus by contact with the ground.

An attempt which almost ended disastrously, was made to fly a modified form of the kite described in a good sailing breeze, but a squall struck it before it was let go. The kite went up, lifting the two men who held it off their feet. Of course they let go instantly, and the kite rose steadily in the air until the flying cord (a Manila rope three eighths of an inch in diameter) made an angle with the horizon of about 45° when the rope snapped under the strain. Tremendous oscillations of a pitching character ensued; but the kite was at such an elevation when the accident happened, that the oscillations had time to die down before the kite reached the ground, when it landed safely upon even keel in an adjoining field and was found to be quite uninjured by its rough experience. Kites of this type have a much greater lifting power than one would at first sight suppose. The natural assumption is that the winged superstructure alone supports the kite in the air, and that the boat body and floats represent mere dead-load and head resistance. But this is far from being the case. Boat-shaped bodies having a V-shaped cross-section are themselves capable of flight and expose considerable surface to the wind. I have successfully flown a boat of this kind as a kite without any superstructure whatever, and although it did not fly well, it certainly supported itself in the air, thus demonstrating the fact that the boat surface is an element of support in compound structures like those described.

Of course the use of a tetrahedral cell is not limited to the construction of a framework for kites and flying-machines. It is applicable to any kind of structure whatever in which it is desirable to combine the qualities of strength and lightness. Just as we can build houses of all kinds out of bricks, so we can build structures of all sorts out of tetrahedral frames, and the structures can be so formed as to possess the same qualities of strength and lightness which are characteristic of the individual cells. I have already built a house, a framework for a giant wind-break, three or four boats, as well as several forms of kites, out of these elements. See AËRODROME; BALLOON; FLYING MACHINES.

ALEXANDER GRAHAM BELL.

Aërians, a religious sect who arose in the 4th century of the Christian Church and present many features of modern religious liberalism in the way they combatted ecclesiastical tradition and the institutionalism professedly derived from the Apostolic age. They derive their name from their originator and leader, Aërius, a presbyter of Sebaste, a city of Pontus. Aërius flourished about 355 A.D. He was fired with a spirit of revolt against the condition of the Church as he found it. Although an ascetic of a very stern and rigid character, he was shocked at the extravagant lengths to which some of his fellow Christians carried the practice of fasting, and the claims which they made to merit because of this rigorous self-maceration. Although he found fasting a settled institution of the Church he opposed the practice because of the delusions it seemed to lead to. He was also an opposer

of those special festivals of intercession which were held in behalf of the faithful departed. "Pray for the living, whose needs and sufferings some of which you may have caused," he seems to say. To this vigorous and uncompromising onslaught on the common and ordinary practices of the Church he recalls such earnest and outspoken fathers of the Reformation as Martin Luther and John Knox. There were a great many people who sympathized and agreed with him, and his sect at one time was very flourishing. The ascendancy of the episcopal order in the Church was a natural aristocratic movement, although Bishop Lightfoot in commentary on the Philippians does not seem to think that it was sanctioned either by divine command or apostolic precedent. Aërius maintained that the bishop was not superior to the presbyter, that they were of the same order, and that a bishop was merely a chairman elected for convenience sake to preside among equals. He seems also to have been opposed to holding of any such set festivals in the Church as Easter. This sect seems to have sown the earliest seed of modern Presbyterianism.

Aërides, the wind flower, one of the *Orchidaceæ*, of which there are 15 species. The finest species, *Aerides adoratum,* grows wild in parts of Asia, but in cold and temperate climates is cultivated under glass, though flowering at rare intervals. This genus of plants derives its name from the fact that the species appear to take their principal nourishment from the air, as they can exist and thrive in their native clime, sending forth blossom after blossom while suspended and far away from any vegetable soil. They bear distichous leaves and their flowers are big and brilliant, while at the same time possessing a rare fragrance.

Aërial Telegraphy. See SEMAPHORE; WIRELESS TELEGRAPHY.

A'ërinite, a bright blue earthy substance found in the Pyrenees. It has no definite composition, and its blue color is perhaps of artificial origin.

A'ërodrome (from two Greek words signifying "air runner"), a form of flying-machine invented by Prof. S. P. Langley, now secretary of the Smithsonian Institution. This machine has never yet been constructed on a scale sufficiently large to sustain a man, but models weighing 30 pounds or so have been built, which, operated by a small steam engine, have worked successfully, and have given fair promise of the solution of the problem of aërial navigation. The aërodrome has no gas bag, but relies for its sustaining power wholly upon its wings and upon the machinery which propels it. Prof. Langley has approached the problem of aërial navigation with greater care and more elaborate preparation than any other man. For years before he undertook the construction of even the crudest of flying-machines he conducted an elaborate series of experiments upon a whirling table in which the supporting action of the air upon almost every conceivable shape of aëroplane, and at all possible velocities, was accurately measured and recorded. As his data, thus obtained, accumulated, he supplemented them by experiments with small models acting freely in the air; sometimes these were mere planes gliding through the air, and sometimes they were machines driven with screws propelled by rubber bands under tension. Having satisfied himself of the possibilities of mechanical flight, he calculated the areas of the sustaining surfaces that he would need, and the best shape to give them. Then came a long and elaborate series of investigations as to the motor best suited for the work, accompanied by the construction of a number of such motors, which were tested, weighed, and found wanting. His final choice was the steam engine, supplied with steam from a plain copper coil for a boiler, through which a circulation was artificially maintained, and which was heated by a gasolene flame from a special jet. Prof. Langley's work on the supporting power of aëroplanes is described in his 'Experiments in Aërodynamics.' He discovered the remarkable fact that in such aërial navigation as was there shown to be possible under certain definite conditions the power required would in theory diminish indefinitely as the speed of the flying-machine increased; and that it would actually diminish, even in practice, up to a certain limit. This apparently paradoxical fact is known as "Langley's law." In the completed form of his aërodrome there are two pairs of wings, which do not move like the wings of a bird, but are fixed to the machine and serve as supporting surfaces. These wings are slightly curved, and each is attached to a long central steel rod for support. From this same rod the body of the machine depends, together with the boiler, the engine, the machinery and the propeller wheels, these latter not being in the position of those of an ocean steamer, but more nearly amidships. They are made of wood, and are between three and four feet in diameter. The boiler supplies steam for an engine of between one and one-and-a-half horsepower; and weighs a little over five pounds, including the fire grate. The engine, with all its moving parts, weighs 26 ounces, and suffices to drive the propeller wheels at a speed of from 800 to 1,200 revolutions per minute. The rudder has both a horizontal and a vertical blade, so as to steer in both directions. The total length of the machine is about 16 feet, and the span of the wings from tip to tip is between 12 and 13 feet. The weight of the whole, including the machinery, is nearly 30 pounds. On the day when the aërodrome made its first successful flight from a houseboat on the Potomac River, at its first launching it made a short, sharp dive into the river. No change was made other than a slight adjustment whereby the centre of gravity of the whole machine was moved about three quarters of an inch; but this was sufficient to give the desired balance, and the second launching was entirely successful.

Prof. Alexander Graham Bell, in 'Nature' for 28 May 1896, describes the famous trial on the Potomac River as follows: "Through the courtesy of Mr. S. P. Langley, secretary of the Smithsonian Institution, I have had on various occasions the privilege of witnessing his experiments with aërodromes, and especially the remarkable success attained by him in experiments made on the Potomac River on Wednesday, 6 May, which led me to urge him to make public some of these results. I had the pleasure of witnessing the successful flight of some of these aërodromes more than a year ago, but Prof. Langley's reluctance to make the results public at that time prevented me from asking

him, as I have done since, to let me give an account of what I saw.

« On the date named two ascensions were made by the aërodrome, or so-called ‹ flying-machine,› which I will not describe here further than to say that it appeared to me to be built almost entirely of metal and driven by a steam engine, which I have understood was carrying fuel and a water supply for a very brief period, and which was of extraordinary lightness. The absolute weight of the aërodrome, including that of the engine and all appurtenances, was, as I was told, about 25 pounds, and the distance from tip to tip of the supporting surfaces was, as I observed, about 12 or 14 feet. The method of propulsion was by aërial screw propellers, and there was no gas or other aid for lifting it in the air except its own internal energy.

« On the occasion referred to the aërodrome at a given signal started from a platform about 20 feet above the water and rose at first directly in the face of the wind, moving at all times with remarkable steadiness, and subsequently swinging around in large curves of perhaps a hundred yards in diameter, and continually ascending until its steam was exhausted, when, at a lapse of about a minute and a half, and at a height which I judged to be between 80 and 100 feet in the air, the wheels ceased turning, and the machine, deprived of the aid of its propellers, to my surprise, did not fall, but settled down so softly and gently that it touched the water without the least shock, and was in fact immediately ready for another trial.

« In the second trial, which followed directly, it repeated in nearly every respect the actions of the first, except that the direction of its course was different. It ascended again in the face of the wind, afterward moving steadily and continually in large curves accompanied with a rising motion and a lateral advance. Its motion was, in fact, so steady that I think a glass of water on its surface would have remained unspilled. When the steam gave out again it repeated for a second time the experience of the first trial when the steam had ceased, and settled gently and easily down. What height it reached at this trial I cannot say, as I was not so favorably placed as in the first, but I had occasion to notice that this time its course took it over a wooded promontory, and I was relieved of some apprehension in seeing that it was already so high as to pass the tree tops by 20 or 30 feet. It reached the water one minute and thirty-one seconds from the time it started, at a measured distance of over 900 feet from the point at which it rose. This, however, was by no means the length of its flight. I estimated from the diameter of the urve described, from the number of turns of the propellers as given by the automatic counter, after due allowance for slip, and from other measures, that the actual length of flight on each occasion was slightly over 3,000 feet. It is at least safe to say that each exceeded half an English mile.

« From the time and distance it will be noticed that the velocity was between 20 and 25 miles an hour, in a course which was constantly taking it ‹ up hill.› I may add that on a previous occasion I have seen a far higher velocity attained by the same aërodrome when its course was horizontal.

« I have no desire to enter into detail further than I have done, but I cannot but add that it seems to me that no one who was present on this interesting occasion could have failed to recognize that the practicability of mechanical flight had been demonstrated.

« ALEXANDER GRAHAM BELL.»

The aërodrome is described, with illustrations, in the ‹ Scientific American Supplement,› Nos. 1404 and 1405; and there was also a popular account in ‹ McClure's Magazine › for June 1897. See also « Story of Experiments in Mechanical Flight,» by S. P. Langley, in the Smithsonian ‹Report› for 1897. For further information on the subject of aërial navigation, see BALLOON; FLYING-MACHINE.

Aërodynam'ics, that branch of hydrodynamics (q.v.) which deals with the properties, and especially the motions, of air and other compressible fluids. See METEOROLOGY.

A'ërolite, a name given to stones falling from the sky. See METEORITE.

Aërol'ogy, that branch of physics that treats of the air. See ATMOSPHERE; METEOROLOGY.

Aëronau'tics, the art of navigating the air by means of balloons (q.v.) or flying-machines (q.v.). See also AËRODROME; AËROPLANE; BALLOON.

A'ëroplane. This word is used in the following two senses: (1) A plane or nearly plane material surface possessed of a certain degree of rigidity, and used in connection with flying-machines to oppose great resistance to the fall of the machine, while allowing it to travel ahead without much resistance. The planes are usually set parallel with the horizontal axis of the machine, or else they are inclined slightly upward so that as the machine is driven forward by its propellers or wings the aëroplane will exert a lifting or sustaining effect. (2) Any flying-machine, but especially that invented by M. Victor Tatin, and tested with a certain degree of success in 1879 at Chalais-Meudon. Tatin's aëroplane was propelled by two screws, which were driven by compressed air. The syllable -plane, in the word in its second sense, is derived from the Greek word *planos*, "wandering." See AËRODROME; BALLOON; FLYING-MACHINE.

Aërosi'derite, a meteorite (q.v.) consisting essentially of metallic iron.

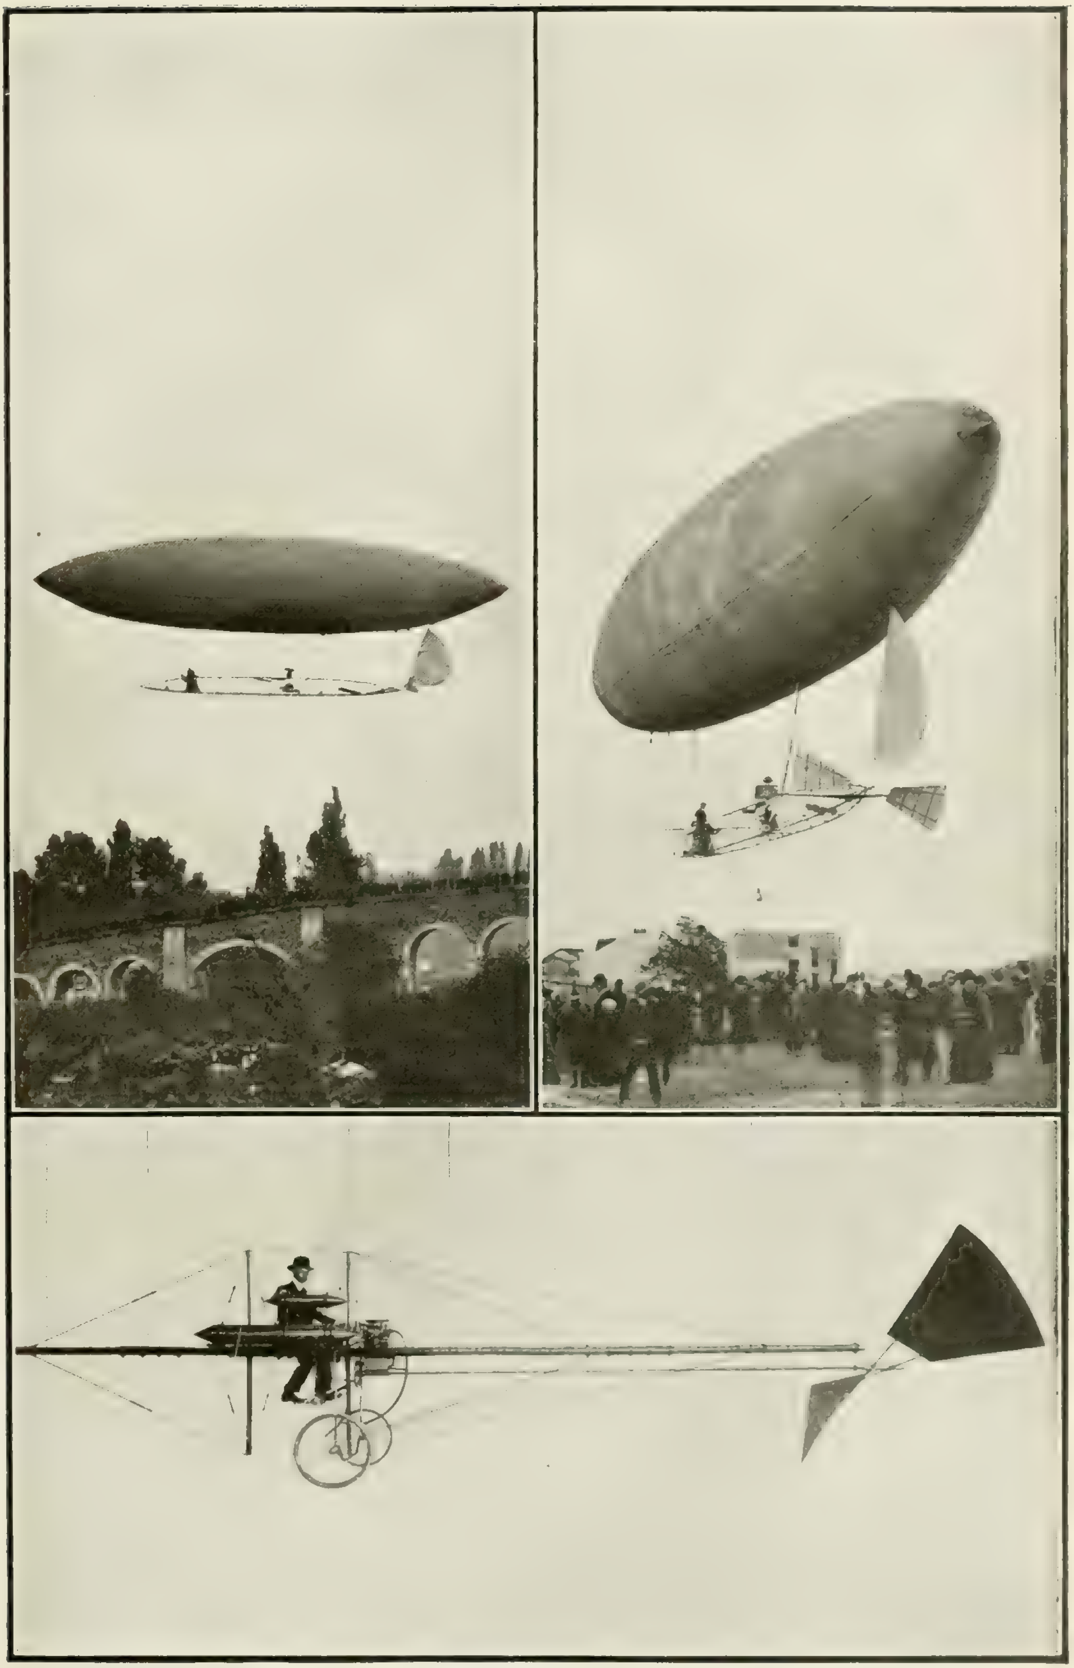
Aërosid'erolite, a meteorite (q.v.) containing both stone and iron. The name comes from the Greek *sideros*, iron, and *lithos*, stone. It was first given by N. S. Maskelyne.

A'ërostat. See BALLOON; FLYING-MACHINE.

Aërosta'tics, that branch of science which treats of the density, pressure, and equilibrium of air and other gases. See GASES, GENERAL PROPERTIES OF; THERMODYNAMICS.

Aërotherapeutics, the treatment of disease through the medium of air. See THERAPEUTICS.

Æschines, es'ki-nēz, the greatest of Greek orators except his rival Demosthenes: b. Attica, 389 B.C.; d. Samos, 314 B.C. That he rose to immense influence and high station by his unaided genius, despite family poverty, would be



[1] Departure of Mr. Santos-Dumont from the Aerostatic Park on his successful trip on which he won the Deutsch Prize of $20,000. [2] The "Santos-Dumont No. 6" maneuvering in midair. [3] Ascent of the Santos-Dumont Dirigible Balloon No. 5 at Longchamps on July 12th.

considered his best title to honor in democratized modern states: it was charged against him as a foul disgrace in Athens. The further « campaign » accusations of Demosthenes — that his father was a schoolmaster's freedman and his mother a public dancer and courtesan, and that he changed the family name to a more genteel form — are valuable only as examples of what passed then for fatal obstacles to public trust and private honor, and the last-named reads curiously in a modern atmosphere. That his father was a poor schoolmaster, and that he worked in the school to help, is probable; more than probable also are his boasts of good blood despite it, as several of the brothers became leading citizens, one of them being on the board of ten *strategoi* which conducted military and foreign affairs. He may have been, as alleged, a professional gymnast: unpaid athletics were too reverently worshipped there to make paid ones seem unnatural. He certainly served a long term of military duty (probably not all at once), and with distinction; for he was in the battles of Mantinea (362) and Tamynæ (349), and for bravery in the latter was deputed to carry home the news and accorded a crown. Meantime he had become a magistrate's clerk; a petty actor; finally secretary to the important political leaders Aristophon and Eubulus, who helped him twice to an election as government secretary. He was now 40 and had not « found himself »; but with the chance of addressing the public his true talent soon became manifest. He quickly acquired an eminent mastery of legal and political knowledge, and became a singularly graceful and effective speaker, with remarkable finish, harmony, and variety of oratorical effect. In 348 he was sent to the Peloponnesus to organize a union of the Greeks against Philip of Macedon, but failed entirely, and doubtless became convinced at that time that any such scheme was permanently impracticable. The next year he went as one of the embassy to negotiate peace with Philip, and on their report (which Grote pronounces « a tissue of impudent and monstrous falsehoods,» not necessarily of their own invention, but acceptance of Philip's word), the Peace of Philocrates (another envoy) was concluded in 346. Philip grew more and more powerful, and Demosthenes more and more urgent for opposition to his plans, which, however plausible,— a Græco-Macedonian union against the barbarians and the East,— could in practice only be carried out, as they at last were, by absorbing Greece in Macedonia. Æschines as steadily supported the Macedonian alliance, and doubtless as honestly, from conviction that for disunited Greece the only choice was between league and conquest — which also was true. In 345 Demosthenes charged him with treason and bribery. He was acquitted without difficulty. Three years later the charge was renewed in Demosthenes' great speech « On the False Embassy »: Æschines rebutted it with success in his speech of the same title. He helped on the Macedonian cause all through the reign of Philip and the early part of Alexander's, accused by the opposing party of being a hired emissary of Macedonia, and returning as much and presumably as just abuse as he received. That the public made the necessary discount is proved by the fact that he lost no credit with them. At last he assumed the aggressive with disastrous results. One Ctesiphon having proposed a golden crown for Demosthenes in recognition of his services to the commonwealth, Æschines impeached him for proposing an illegal act, and made his greatest speech, « Against Ctesiphon,» an indictment of Demosthenes' entire public life. Demosthenes replied with *his* greatest, « On the Crown »; so crushing that though the pro-Macedonian party was in the ascendant Æschines could not obtain the one-fifth minority of votes legally necessary to save him from *atimia*, or infamy, and a fine of 1,000 drachmas. He left Athens at once without paying it, and thereafter taught rhetoric or schools of oratory in foreign parts; some say Ionia and Caria, and finally Rhodes after Alexander's death. He died at Samos, aged 75. Three of his orations are extant,— against Timarchus' charge of bribery after his second embassy to Philip, one on that embassy, and the one against Ctesiphon. There is a story that he read the latter to his pupils at Rhodes, and on their professing to be astonished that despite its brilliancy he should have been defeated, replied, « You would not be if you had heard Demosthenes.» A variant is that he read Demosthenes' speech as a model of rhetoric, and on their expressing admiration, replied, « If you had heard him roll it out himself! » (The originals are in countless editions. See for text and best comment, Jebb's ‹ Attic Orators,› London 1876–80. Translations are also plentiful.)

Æschylus, es'ki-lus, the eldest of the three great tragic poets of Greece: b. Eleusis, Attica, 525 B.C.; d. 456. Euphorion, his father, was probably connected with the mysteries of Demeter, and he is said himself to have been initiated. In 499 B.C. he made his first appearance as a competitor for the prize of tragedy, but was not successful. Before attaining his first triumph he had to appear as an actor on a grander scene. He was present, and highly distinguished himself, at the battles of Marathon, Artemisium, Salamis, and Platæa. He must have gained as a poet by his experience in this momentous struggle, and probably too his fame as a warrior would help to recommend his compositions as a poet to his countrymen. His first dramatic victory was achieved in 484 B.C. The names of the pieces which composed his trilogy at this time are not known. The ‹ Persæ › (‹ Persians ›), the earliest of his extant pieces, formed part of a trilogy which gained the prize in 472 B.C. Altogether he is reputed to have composed 70 tragedies and gained 13 triumphs. In the satirical pieces which accompanied the trilogy of tragedies he is said also to have been a master. Only seven of his tragedies are extant. They are: ‹ The Persians › (remarkable as being founded on contemporary events), ‹ The Seven against Thebes,› ‹ The Suppliants,› ‹ Prometheus Bound,› ‹ Agamemnon,› ‹ The Choephori,› and ‹ The Eumenides.› The last three form the trilogy of the ‹ Oresteia › (so named as being based on the story of Orestes), the only complete Greek trilogy we possess. It was represented in 458 B.C., between which date and that of ‹ The Persians › the others were brought out; but, according to a suggestion of Böckh, the representation of the ‹ Oresteia › in 458 B.C. was a repetition in the absence of the poet.

In 468 B.C. he was defeated by Sophocles, and is said to have retired through mortification at this defeat to the court of Hiero, king of Syracuse. Of the fact of his residence at Syracuse at this time there appears to be no doubt, and without ascribing his retirement to mere jealousy, there are other reasons for associating it with his defeat. Æschylus belonged to the old aristocratic party, which had long been on the decline. His rival Sophocles, whose first appearance as a dramatist had thus been honored with a triumph, was favored by the democratic party, Cimon himself being one of the judges. The decline of his party might thus render Athens an uncongenial residence to Æschylus, and indispose him for an arduous contest in which he did not feel that justice was done to his claims. During his residence at Syracuse he composed many pieces, in which he not only selected local subjects, but used words unintelligible to the Athenians. Unless Böckh's theory is received it must be supposed that Æschylus returned to Athens for the representation of his ‹Oresteia.› There is a story that he was accused before the Areopagus for impiety either in representing the « Eumenides » on the stage or in divulging the mysteries of Demeter; and it is to the period of this representation that the accusation is usually referred. If Æschylus came to Athens he must soon have returned to Sicily, where he died in Gela. A tomb was erected to him, with an epitaph by himself, in which he speaks of himself as an exile from Athens, and refers to his part in the battle of Marathon, but not to his writings. Of the manner of his death an improbable story is told, namely, that an eagle, mistaking his bald head for a stone, let fall a tortoise on it to break the shell, and thus killed him.

Æschylus was in a sense the creator of the Greek tragedy, the stage up till his time being occupied with comparatively feeble productions. His style, as is common with early poets, was grand, sublime, and full of energy, though sometimes erring in excessive splendor of diction and imagery. Longinus, the celebrated Greek critic, complains of it as being often harsh and overstrained. His plays have little or no plot, and in personal portraiture he does not represent the subtle complexities of human character, which belong to a later development of art, but the bold outlines of strength and daring which pertain to the conception of gods and heroes. A fatalistic tendency dominates his views of the unseen, and by making men the sport of superior beings supplies abundant material for tragedy. An ethical principle of retribution is not, however, wholly lost sight of. The practice of contending for the prize with a trilogy of plays was established before his time, but he was the first to reduce the trilogy to a unity by linking together three distinct but associated subjects, each of which formed the theme of a play complete in itself yet related to the others.

Æschylus was a great improver of the stage as well as of the drama. He introduced a second actor upon the scene, and was thus the founder of true dramatic dialogue, to which he subordinated the chorus, which had formerly been the principal part. At a subsequent period he followed the example of Sophocles in introducing a third actor. The dialogue he introduced was measured and formal, and without the license of broken lines. This gave it a distant and stately character agreeable to the kind of superhuman heroes which it suited the genius of Æschylus to put upon the stage. To make the appearance of his personages suitable to their character, he introduced the thick-soled cothurnus or buskins to raise the stature of the actors, and he gave them dresses appropriate to the parts they had to play. He himself sometimes acted in his own plays. He also made use of the scene-painter's services, and Agatharchus is said to have painted for him the first scenes drawn according to the laws of linear perspective. From the testimony of Aristotle, however, it seems to be doubtful whether scene-painting was actually introduced by Æschylus or Sophocles. After its introduction it would no doubt be used by both. He carefully trained the dancers to represent incidents in the play by appropriate action, and he removed from the stage scenes of violence and blood. By a special decree of the Athenian people a chorus was provided at the public expense for any one who wished to produce any work of Æschylus a second time. After his death his sons Euphorion and Bion, and his nephew Philocles, gained triumphs with works of his over Sophocles and Euripides, and thus was established a tragic school of Æschylus, which continued to flourish for more than a century.

The first edition of Æschylus was printed in Venice in 1518. The best of the earlier editions was that of Stanley (London, 1663). The best recent editions are those of Ahrens (Paris, 1877), Wecklein (Berlin, 1884) and F. A. Paley (in the ‹Bibliotheca Classica›). There are English poetical translations by Potter, Blackie, Plumptre, Morshead, and Swanwick, and a prose translation by Paley. Fitzgerald's semi-translation of the ‹Agamemnon,› with the widest liberties of omission, addition, and recasting, though of no very great service to the scholar, is of incomparable poetic brilliancy, and far the best introduction to make the general reader feel Æschylus' greatness and charm. Robert Browning also has one of the same play, and Elizabeth Barrett Browning one of the ‹Prometheus.›

Æs'chynite, es'ki-nīt, the mineral for which Dana's Æschynite group was named. It is essentially a niobate, titanate and thorate of the cerium metals, containing also iron and calcium in small amounts. It occurs in black, prismatic, vertically striated crystals belonging to the orthorhombic system. Its hardness is about 5.5, and its specific gravity about 5. It is rare, and occurs in the Ural Mountains, in Norway, and in Silesia. It was named by Berzelius from a Greek word meaning "shame," in allusion to the "shameful" inability of chemistry, at the time of its discovery, to separate titanic acid and zirconia (two of its constituents).

Æscula'pius (Greek *Asclepios*), the god of medicine among the ancient Greeks and Romans. In Homer he is merely a man, the god of medicine being Pæëon; the deification was probably founded on the Homeric story, and at any rate was subsequent. The notion that he was originally a god of light or the underworld, « reduced » to the tradition of a human being,

inverts all historic processes and the nature of early thought. In Homer he has two sons, Machaon and Podalirius, famous as heroes and physicians; they are called Asclepiadæ, a name retained by their descendants or at least a priestly physician-caste. His daughters, Hygeia (health), Panacea (all-healer), Iaso (healer), etc., are later inventions, abstractions of relevant ideas. The later myths vary: some call him son of Apollo and Arsinoe, some of Apollo and Coronis daughter of Phlegyas. In Hesiod the nymph was faithless, and with her bridegroom Ischys (one of the Lapithæ) was slain by the gods (the raven who brought the news being changed from black to white as a punishment); but Apollo rescued his unborn son from the mother's body on the funeral pile, and put him under charge of Chiron, where he grew to excel his master, able not only to prevent death but to raise the dead. At Pluto's complaint Zeus slew him with a thunderbolt, and after his death he received divine honors. The supposition that his worship originated in the Peneus Valley in Thessaly is perhaps due to the Homeric tradition being our earliest record; but if he was originally a healer wonderful to rude barbarians, it is likely enough that the tradition was Thessalian. Anyway, Tricca there was an old focus of his cult; but it flourished also to the south, perhaps carried there by the Thessalians forced southward by invaders. It had noted seats in Phocis, Bœotia, and especially in the Peloponnesus, where Thelpusa in Arcadia was one familiar seat; but by far the greatest was Epidaurus south of Corinth. Here was a temple in a grove, where the sick had to spend a night, and the proper remedies were revealed to the priests in a dream, and the cured made sacrifice to Æsculapius, commonly a cock. The sleep was of course a mere part of the priests' mystification; but from their accumulated experience and their register of cases they must have became really expert physicians for the times. From thence the worship spread all over Greece and the islands and to Rome,— nearly 200 temples in all; there were celebrated ones at Cos, Cnidus, and Pergamus; the cult was introduced into Athens as late as 420 B.C., and to Rome 293 B.C., in consequence of a plague. (Walton, ‹The Cult of Asklepios,› New York, 1894; Wilamowitz-Möllendorff, ‹Isyllus von Epidauros,› Berlin, 1886.)

Æs'culin, es'cu-lin, a bitter principle found in the bark of the horse-chestnut tree (*Æsculus hippocastanum*), especially in the spring, before the buds open. It crystallizes in small prisms having the formula $C_{15}H_{16}O_9.2H_2O$. Æsculin melts at 400° F. It dissolves sparingly in cold water, but easily in boiling water, the solution coagulating upon cooling. It is soluble in glacial acetic acid and in 24 parts of boiling alcohol. Æsculin is of special interest to the physicist on account of the notable bluish fluorescence (q.v.) exhibited by its solution in water. The word is also spelled æsculine, esculin, and esculine.

Æ'sop, the fabulist. As early as the mid-5th century B.C. at least, fables were circulating in Athens attributed to a certain Æsopus, and held in such esteem that the city erected to him a statue by the great sculptor Lysippus; Aristophanes makes one of his characters learn the fables, Socrates versified such as he could remember, and Plato speaks of them with approval; Herodotus, born c. 484 B.C., specifically tells us, as referring to a story too familiar to repeat, that when the Delphians offered compensation for his murder to the rightful claimant, it was claimed and received by one Iadmon, grandson of another Iadmon, a Samian and owner of Rhodopis the courtesan, who lived under Amasis, king of Egypt (c. 570–526 B.C.), and was redeemed by Charaxus, the brother of Sappho. That all this mass of detail concerning persons living less than a century before his time, with easily verifiable dates, and about one whose fate was notorious, was in fact told of a myth and abstraction, and that there never was an Æsop, is exaggerating skepticism into absurdity; and the later accretion of fables and confusion of persons is irrelevant. Plutarch (late 1st century A.D.) fills out the story from lost authors, possibly with authentic traditions, perhaps mixed with real myth-making: that he was captured young and brought a slave to Athens, and after several changes of ownership enfranchised by Iadmon (which is inconsistent with Herodotus); that during Pisistratus' usurpation he visited Athens and composed the fable of «King Log and King Stork» for the edification of the citizens; that, going to the Lydian court, he became Crœsus' favorite, was sent by him as envoy to Delphi to distribute money to the people (about 564 B.C.), and, refusing to do so on account of a quarrel among them, was thrown from a cliff by them. This at least coheres with Herodotus. The stories of his being an ugly blackamoor, and others beyond the above, are derived from a worthless life of him published (but not written) by Maximus Planudes (q.v.), a 14th-century monk, in which he is apparently confounded with the mythical Oriental sage Lokman. As to the fables, it is probable that Æsop did not write them down, but merely told them to audiences: and it is perfectly certain that the ones we have under his name are not his (though they may incorporate the same incidents), but substantially a collection made from oral memories by Demetrius Phalereus of Athens about 320 B.C.; turned into Latin by Phædrus of the 1st century A.D., with additions of his own much inferior in every way; versified by Babrius, a Greek poet of perhaps the late 1st century; and variously translated and re-edited since. The usual popular «Æsop» is Phædrus. The origin of the fables is largely Oriental; but they are much superior to any Oriental prototypes in pith and conciseness. It is often said also that they are part of the stock of beast-apologues common to the entire Indo-European races; but this is true only in the sense that animals have been made to talk in all old folk-lore. The special qualities of «Æsop»— the immense compression of idea almost to «indecent exposure,» in Sydney Smith's phrase, the sweep of generalization, the acute analysis of typical human characteristics — make it unique; and it quite probably inherits these traits from the genius of the real Æsop, a Greek of the mighty age of Greece.

Æso'pus, Clodius, a celebrated Roman actor of the 1st century B.C., a contemporary of Roscius. When acting he entered into his part to such a degree as sometimes to be seized with a perfect ecstasy. Plutarch mentions a report

concerning him while representing Atreus, that, deliberating how he should revenge himself on Thyestes, he was so transported beyond himself that he smote one of the servants who was crossing the stage and killed him on the spot. He was a dramatic tutor of Cicero, and befriended him in exile. His last appearance was at the dedication of Pompey's Theatre in 55 B.C.; his voice thereafter failed. His folly in spending money on expensive dishes made him as conspicuous as his dramatic talents. He is said, at one entertainment, to have had a dish filled with singing and speaking birds, which cost $4,000. His son Æsop inherited his father's worst traits: it was he who drank the $40,000 pearl dissolved in vinegar, to be noted as having drunk the most expensive known beverage.

Æsthetics, the science of beauty, in its emotions or attributes. The term æsthetics first received this application from Baumgarten, a German philosopher, who was the first modern writer to treat systematically on this subject. Kant uses the word æsthetics (*aisthetikos*, perceivable by the senses) in a broader etymological sense, treating in his transcendental æsthetic of the *a priori* principles of sensuous knowledge. There are, as indicated, two modes of treating æsthetics, scientifically or empirically, by collection and collation of the objects or associations by which the æsthetical emotions are excited, and philosophically by analysis and determination of the cause or source and mode of the emotions. Neither of these modes is independent of the other; but the scientific mode, from the multitude of details it involves, is little amenable to summary treatment, and in form at least we shall be compelled to limit ourselves to the other.

Æsthetics, like every other branch of philosophy, has suffered from the conflict of first principles which has continually impeded the development of details; but it has also profited by this conflict, which has itself brought out facts which might otherwise have been hid. Space will not permit a historical summary, and we confine ourselves to the briefest indications of the views of the leading thinkers.

Socrates, according to Xenophon, regarded the beautiful as coincident with the good, and both as resolvable into the useful. Plato, in accordance with his idealistic theory, held the existence of an absolute beauty, which is the ground of beauty in all things. He also asserted the intimate union of the good, the beautiful, and the true. Aristotle, whose contributions to æsthetics are of the highest value, treated of them in much more detail than Plato, but chiefly from the scientific or critical point of view. In his « Poetics » he declares poetry to be a more serious and philosophical matter than philosophy itself. In his treatises on « Poetry » and « Rhetoric » he lays down a theory of art and establishes principles of beauty. His philosophical views were in many respects opposed to those of Plato. He does not admit an absolute conception of the beautiful; but he distinguishes beauty from the good, the useful, the fit, and the necessary. He resolves beauty into certain elements, as order, symmetry, definiteness, and a certain magnitude, which appears to be relative to the perceptive capacity. A distinction of beauty, according to him, is the absence of lust or desire in the pleasure it excites. Beauty has no utilitarian or ethical object; the aim of art is merely to give immediate pleasure; its essence is imitation; the chief objects of imitation in poetry and music are passions, dispositions, and actions. The essence of poetry consists in this imitation, and not in form. The end of tragedy, he says, is to effect a purification of pity and fear by means of these passions themselves. He also speaks of a purifying effect of music in quieting wilder forms of excitement. As this seems a contradiction of his negation of an ethical end in æsthetics it has been disputed whether this purification is ethical or æsthetical. Plotinus agrees with Plato and disagrees with Aristotle in holding that beauty may subsist in single and simple objects, and consequently in restoring the absolute conception of beauty. He differs from Plato and Aristotle in raising art above nature. When the artist has *logoi* (the equivalent in the system of Plotinus of the ideas in that of Plato) for his models his creations may be more beautiful than natural objects. Baumgarten's treatment of æsthetics is essentially Platonic. He made the division of philosophy into logic, ethics, and æsthetics; the first dealing with knowledge, the second with action (will and desire), the third with æsthetics.

Where Baumgarten fails of a Platonic standard is in limiting æsthetics to the conceptions derived from the senses, and in making them consist in confused or obscure conceptions, in contradistinction to logical knowledge, which consists in clear conceptions. Kant defines beauty in reference to his four categories, quantity, quality, relation, and modality. In accordance with the subjective character of his system he denies an absolute conception of beauty, but his detailed treatment of the subject is inconsistent with the denial. Thus he attributes a beauty to single colors and tones, not on any plea of complexity, but on the ground of purity. He holds also that the highest meaning of beauty is to symbolize moral good, and arbitrarily attaches moral characters to the seven primary colors. The value of art is mediate, and the beauty of art is inferior to that of nature. He classifies the arts according as they express the (subjective?) æsthetic idea. The treatment of beauty in the systems of Schelling and Hegel can with difficulty be made comprehensible without a detailed reference to the principles of these remarkable speculations. Idealistic systems, which, to say the least, it is difficult to distinguish from pantheism, while it is impossible to find a beauty and even sublimity in the boldness of their developments, they may be described from an outside point of view as exaggerations of Platonism, in which human consciousness is made the exhaustive measure of universal being. The control of subject and object, which with Schelling constitutes the absolute, is seen in artistic conception within the limits of the ego, and a feeling of infinite satisfaction accompanies this perfect perception by intelligence of its real self. Art accordingly is higher than philosophy, and the beauty of art is superior to the beauty of nature. Schelling's views of art are not clearly developed into particular criticism. In tragedy he finds a conflict of liberty in the subject with objective necessity. In art, according to Hegel, the absolute is immediately present to sensuous perception. With him, as with Schlegel, it is the highest revelation of beauty and superior to

nature. The beautiful is the shining of the idea (the Hegelian idea, or absolute notion into which all existence is resolvable) through a sensuous medium. Its essence accordingly is in appearance, and in this it differs from the true. Its complement is religion, which embodies the certainty of the idea.

Hegel classifies the arts according to the supremacy of form and matter, a classification which appears somewhat superficial and is very open to criticism. He treats of beauty in much detail, and where he is not Hegelian he is essentially Platonic. The extravagance of Hegelianism, along with its pantheistic tendencies, become more pronounced in the systems of the followers of Hegel, into which we have not space to enter. English writers on beauty are numerous, but they rarely ascend to the heights of German speculation. Shaftesbury adopted the notion that beauty is perceived by a special internal sense; in which he was followed by Hutcheson, who held that beauty existed only in the perceiving mind, and not in the object. Numerous English writers, among whom the principal are Alison and Jeffrey, have supported the theory that the source of beauty is to be found in association — a theory analogous to that which places morality in sympathy. The ability of its supporters gave this view a temporary popularity, but its baselessness has been effectively exposed by successive critics. Dugald Stewart attempted to show that there is no common quality in the beautiful beyond that of producing a certain refined pleasure; and Bain agrees with this criticism, but endeavors to restrict the beautiful within a group of emotions chiefly excited by association or combination of simpler elementary feelings. Herbert Spencer avails himself of a hint supplied by Schiller, which he makes subservient to the theory of evolution. He makes beauty consist in the play (sport) of the higher powers of perception and emotion, defined as an activity not directly subservient to any processes conducive to life, but being gratifications sought for themselves alone. He classifies æsthetic pleasures according to the complexity of the emotions excited, or the number of powers duly exercised; and he attributes the depth and apparent vagueness of musical emotions to associations with vocal tones built up during vast ages. Among numerous writers who have made valuable contributions to the scientific discussion of æsthetics may be mentioned Winckelmann, Lessing, Jean Paul Richter, the Schlegels, Gervinus, Helmholtz, and Ruskin.

The theory of Plato affords, we believe, the true basis both of philosophical apprehension and of scientific investigation of the beautiful. What is meant when it is said there is no common quality in what is recognized as beauty beyond the excitement of a pleasurable emotion? It is not pretended that all pleasurable emotions are comprehended in the notion of beauty: the mere excitement of pleasure is not then sufficient to distinguish the notion. Is the use of the term then a mistake, and does it imply nothing more than the arbitrary grouping together of some pleasurable emotions to the exclusion of others? We have the most conclusive psychological evidence in the structure of all languages that this is not the case, and that there is some notion, simple or complex, subjective or objective, requiring this term to express it. If, then, we attempt to distinguish between pleasurable emotions, and to group them as emotions of beauty or emotions not of beauty, we must either suppose our emotions to be self-excited, or we must assume a corresponding difference in the exciting cause. We have thus got both an objective and a subjective beauty and it remains to inquire into the nature of the object, whether real or phenomenal, simple or complex, by which the notion of beauty is excited. Association cannot be an original cause of the emotion, for association as such, and without regard to the nature of the association, can excite no definite emotion such as that of pleasure. If the notion of beauty then is actually excited by association, as it undoubtedly is, it remains to be inquired by what association, and by what elements of the association? Nor can the explanation of Aristotle and other philosophers be received, that beauty is merely a recognition of harmony, proportion, symmetry, and such modes in complex objects, for it is as undoubted that there is a self-beauty, the beauty of a straight line in being straight, of a circle in being round, or of blueness in being blue, as that there is a beauty of harmony and proportion. Lastly, we cannot limit beauty to the objects of the senses; all that is perceived by intelligence, whether in the forms or processes of matter, or in the states or operations of mind, is capable of exciting the emotion of beauty. There is then no common category in which the beautiful can be included except the beautiful. It is not the useful, or the good, or the true, the great or small, the high or low, but the beautiful. But Plato has also shown that our ideas, though not resolvable into each other, are mutually dependent and related. They are united in concrete thought and apprehension, and they form in their totality a whole which constitutes the oneness of intelligence. If beauty then cannot be resolved into other notions, its relations to and combinations with these notions can be traced, and this constitutes its philosophical definition.

Our knowledge is indeed too limited to enable us to trace all the relations of ideas which are infinite, but a just use of psychology enables us to apprehend in their simplest form even the highest verities, and Plato, in associating in one triad beauty, goodness, and truth, has expressed the highest relation and evolved the highest knowledge attainable of them. The psychological evidence of this union lies within the range of experience, and its generalization is the legitimate operation of reason. To a limited intelligence goodness and truth (or reality) seem often wide apart, but every intelligence must apprehend the desirableness of their union, and occasionally witness practical exemplifications more or less perfect of it. If uniting such partial realizations we assume that to a perfect intelligence truth and goodness would be in perfect unity, the contemplation of this union will excite in us the highest emotion of beauty. This, then, may be regarded as both the type and the exhaustive realization of the notion of beauty. This trinity has, as indicated also by Baumgarten, a relation to the distribution or natural operation of our faculties. We have reason to apprehend truth, imagination to perceive beauty, and conscience to recognize goodness. Imagination as a mental faculty must not

be understood as a mere power of reproducing objects of sense in the form of pictorial images. It is the mental power by which we apprehend and combine at will all the elements directly presented to our consciousness, whether from external observation or internal experience. It, as well as reason, is operative, but it differs from reason both in its mode of operation and in its end. Instead of the slowly elaborate process by which reason searches out the true relations of its objects, it seeks by the readiest process objects of immediate contemplation on which it can dwell with satisfaction, and accordingly selects for combination those elements which present to it the most immediate affinities. In its constructive data it is as comprehensive as reason, but in its processes it is less sure. It even forms hypotheses, that is, semblances of reason, but it leaves reason to verify them. Hence the reason why the perception of the beautiful has been assigned to an inner sense. Hence also the reason why the apprehension of beauty separates itself from the apprehension of truth and of goodness.

The apprehension of beauty is always the apprehension of some perfection, of some identification of the good in the real, but in order to produce the emotion of beauty this identification must be manifest. This it is, and this alone apparently, which associates beauty with the work of imagination rather than with the work of reason, and makes the former the special faculty of beauty. The processes of reason are slow and their results remain long imperfect; thus there is no immediate realization of the perfection of truth attained by them; but when some final discovery completes a chain of reasoning, and a whole truth stands revealed, there is an immediate perception of goodness in the completed truth, and the emotion of beauty is at once evoked. The work of imagination is subject to the review of reason, but as reason and imagination work on the same fundamental principles, it is the application of these principles alone which reason can review. Particular manifestations of beauty are thus capable of analysis, and we may resolve the elements of the most complex manifestations into two, self-beauty and beauty of combination. The first exists when the simple type or idea is realized in the example, when a straight line is straight, a circle round, a color or a sound pure. When a type is suggested by simulation, on the contrary, but so imperfectly realized that the defect is apparent, the result is ugliness. It thus needs no metaphysics to distinguish beauty from its opposite. In combination beauty is given when perfect types are combined according to laws of symmetry, proportion, and design. Every single curve, for example, has a particular law, and that curve is beautiful when produced according to its law: but when a variety of curves are combined according to some law of symmetry in one outline, there is, besides the self-beauty of the several curves, a beauty in the observance of the law of combination, and in this complex beauty of outline, besides the manifested beauty of form, there may be suggested beauties of suppressed continuations. So with combinations of sound and color and more complex combinations, as in the forms of animal and vegetable life.

Two related laws of beauty in combination appear to be the production of the greatest variety with the least expenditure of means, and the repetition under slight modifications of similar forms. The latter from the comparisons it suggests has a highly educative effect on the perceptive faculties. Thus all the canons of beauty are absolute, but as these canons are applicable only to the elements, whether of self-beauty or of combination, and as we are ignorant of the laws which determine the number and variety of the more complex combinations, which we learn to know only by observation and comparison, principles of criticism only can be formed, and no absolute standard of taste for common empirical observation. Diversities of opinion are thus easily accounted for. The existence of beauty in the object is distinct from its perception, and in a complex object each observer will perceive only those beauties which the capacity and training of his own faculties enable him to perceive. Even the demonstration to reason of the observance of a law of beauty will not help a defective capacity. The instrumentality of our senses in interpreting to us the beauties of nature demands particular attention. Beauty in an object implies relation of the object to mind in which the canons of beauty exist, but not surely to the perceiving mind only, but also to the conceiving or creating mind. The perception of beauty thus establishes a community between the perceiving and the creating mind. It is an evidence of the validity of the information we derive from those operations of our senses which are deemed most arbitrary. It is the stamp of the Creator on the instruments of our faculties.

It is easily possible for art within a narrow range to excel nature, for while nature supplies our types she rarely carries out in any individual example all the details of typical excellence variously presented. The whole causes of these deviations of nature from her own standards it is impossible to assign, but observation shows that ethical causes have a place among them, and the best reason of men has always inclined to give them a larger place than actually appears. In this also art imitates nature, but in this wider sphere to suppose that art could excel nature would be to assume the superiority of man to the Author of nature. There is thus no ethical indifference for art. To limit it to the mechanical imitation of nature, or the mere selection and combination of æsthetical types without an ethical purpose, would be to place it below the level of reason, and to contradict instead of imitate nature. In assigning a purifying effect to art Aristotle spoke truly as a critic and historian, and to denude this purification of an ethical significance would be to lower his authority as a witness, but not to alter the fact. No canon of criticism is more frequently repeated at the present day than that of Aristotle, that art is without ethical end. This criticism, however, is not true to nature. Art cannot cease to be æsthetical in order to be ethical. It must always deal with the perceptive, but within its own province it is subject to its own ethical code, and it has besides affinities with the general ends of ethics which cannot be ignored with impunity. The pleasure it affords must always be pure, and it may also be instructive. Gayley & Scott, 'Guide to the Literature of Æsthetics'; B. Bosanquet, 'History of Æsthetics.'

Aëta. See NEGRITOS.

Æthel, prefix in Anglo-Saxon names. See ETHEL.

Æthelbold. See ETHELBOLD.

Æthelhard. See ADELARD.

Ætheling. See ATHELING.

Æther. See ETHER.

Æthiopis, Greek epic poem in five books by Arctinus of Miletus. Its heroine is Penthesilea, the Amazon queen, and its story is that of the events of the Trojan war which occurred after those narrated in the 'Iliad.'

Æ'thiops Martial, an old pharmaceutical name for black oxid of iron.

Æ'thiops Mineral, a name sometimes given to the artificial black sulphide of mercury.

Æ'thogen, a compound better known as nitride of boron. See NITRIDES.

Æth'rioscope, eth'ri-ō-skōp, a form of differential thermometer devised by Sir John Leslie. Both bulbs of the thermometer are enclosed in a concave mirror, one of them being in its focus. The instrument is so sensitive that when directed toward the sky it is affected by a passing cloud. It is not much used at the present time.

Aëtius, ā-ē'shius, the last great Roman general and savior of western Europe from being Hun: b. Durostorum on the Danube (now Silistria), c. 390 A.D.; murdered toward the end of 454. He was son of a distinguished commander Gaudentius (probably barbarian); in military service while a boy, and given to Alaric as a hostage after Pollentia in 403, remaining three years; later a hostage to the Huns; and gaining close intimacy with both races, of mixed results. After Honorius' death he supported the secretary Joannes against the empress-regent Placidia, and brought an army of 60,000 Huns to his aid; but, Joannes having just been defeated and slain, the Huns were bribed to go home, and Aëtius was made count of Italy and commander of the army, and became the chief adviser and prop of Placidia and her children. His main rival was Boniface, Count of Africa, at Carthage: and the accepted story is that by a base double intrigue he drove him into revolt and calling the Vandals from Spain into Africa; that on discovering the fraud Boniface fought in Italy first a slight battle and then a duel with Aëtius, was mortally wounded, and in dying counseled his wife to marry no one but his rival. It is very suspicious; but any way the Vandals overran North Africa; Boniface was killed; Aëtius in 432 had to flee to the Huns, came back the next year with an army of them, was reinstated, and for the next 17 years was the ruling spirit in the Western Empire, battling in Gaul with Visigoths, Burgundians, and Franks, upholding by combined soldiership and policy the declining state, with a vigor and genius which made him the one great man of the Roman world in foreign eyes. In 450 the great Hunnish invasion under Attila (q.v.) came rolling down into Gaul with a volume it seemed impossible to stay, and the success of which might have blighted western Europe as their kinsmen the Turks have blighted the eastern portion. Aëtius by his diplomatic skill and knowledge of how to play on the barbarians induced Theodoric the Visigoth to league with him, followed Attila into the Seine valley, and on 20 Sept. 451 checked his progress in the mighty battle of Châlons (q.v.); the empire's last victory, and one of the world's turning-points. Attila's death not long after broke up the Hunnish coalition and delivered the empire from it; but it was also Aëtius' death sentence, and with his the empire's. Valentinian III., Placidia's son, hated Aëtius' power and had only submitted to it from fear of Attila; and, feeling now secure, seized the occasion of a visit of Aëtius to Rome, to arrange the marriage of his son with Valentinian's daughter, and stabbed him with his own hand. The sack of Rome by the Vandals shortly followed; and 22 years after Aëtius' murder the last of a succession of puppet emperors was pulled down by the barbarian Odoacer.

Æt'na. See ETNA.

Ætolia, ancient Greece, a district lying along the N. shore of the Gulf of Corinth and having Epirus and Thessaly N., Acarnania W. separated by the Acheloüs, and Locris and Doris E. separated by the Daphnus. The only other river of any size was the Evenus. Between it and the Acheloüs lies a marshy but fertile plain, separated by the Aracynthus range on the north from a similar plain, of which two large communicating lakes — Trichonis (Apokuro) and Hyria (Zygos) — take up a great part. The rest of the country is crossed in all directions by rugged mountains, covered with forests, and intersected by ravines. The plains produced plenty of corn and fine pasture, and the Ætolian horses were famous, while the mountain slopes gave excellent wine and oil; but for some reason the tribes never till late in Greek history entered into the fellowship of Greek civilization, and then but imperfectly. They were wild, backward, anarchic, and untamable; a race of robbers and pirates, and the best recruiting-ground in Greece for mercenary soldiers. In the Heroic age, when most other Greeks were like them, and Odysseus' grandfather won distinction as an accomplished *klepht,* they were conspicuous; and Ætolia was the scene of the Calydonian boar hunt. (See MELEAGER.) When they reappear in Thucydides' pages on the Peloponnesian war, they are a congeries of unfederated independent tribes, living by plunder and the chase, with few and poor towns,— Thermon, Calydon, and Pleuron the chief,— and taking to the mountains when hard pressed. They had a sort of union like the Iroquois League, for common action against a common enemy, but no corporate accountability and nobody to make a treaty with. After Alexander's death Antipater and Craterus invaded the country; and this, with the great new wealth their general trade of soldiering was bringing in and consequent increase of civilized interests, forced them to strengthen the bond into the Ætolian League, first mentioned in 314 B.C., but of immense weight in later times and chief rival to the Achaian League and Macedonia. Unlike the former, it was a league of tribes, not towns. But like that, it was a democracy nominally, every freeman over 30 having a vote if he could come to the capital and cast it, but an aristocracy

or timocracy in practice, only the wealthier being able. There was a Great Council, or Panætolicon, which met yearly at Thermon, elected all magistrates afresh, and enacted general laws and voted on foreign policy; a smaller body of Apocletæ, who were in fact a cabinet, who prepared all questions to put before the Great Council and seem to have been permanent; a chief magistrate, the *strategos* (general), who was not only military commander but president of the assembly, put such questions as he chose (Speaker), was elected annually, and was not allowed a vote on the question of peace or war; a *hipparchos* or cavalry commander; and a chief secretary. After the expulsion of the Gauls from Greece in 279, in which the League did good service, it expanded enormously; not like the Achaian League because of the advantages of its membership, but from the exceeding disadvantages of its hostility — for it never lost its piratical character wholly to its latest day. It took in Locris, Phocis, and Bœotia, Acarnania, southern Thessaly, and Epirus, many cities in the Peloponnesus, Thrace, and Asia Minor, and the island of Cephallenia; it controlled the oracle at Delphi and the Amphictyonic Council. But its wanton invasion of Messenia (S.W. Peloponnesus) in 220 brought the Achaian League and Macedonia both against it: Philip V. invaded Ætolia in 218, sacked Thermon with its vast accumulated national treasures, and burnt the sacred buildings; and the next year they made peace. In 211 they again provoked a war with Macedonia, and again Thermon was captured, peace being made in 205. In 200 they joined Rome against Macedonia, and helped to win the battle of Cynoscephalæ, which crushed Philip; but they were so disgusted with Flamininus' settlement of the country without giving them the advantages they expected, that in 192 they made the fatal error of allying themselves with Antiochus of Syria against the Romans. Antiochus was crushed in 189, and the independence of the League came to an end. In 167 the pro-Roman party murdered 550 of the patriot leaders, and the League was dissolved and Ætolia made a Roman province.

Affection, in psychology, is a mental element co-ordinate with «sensation.» See FEELING.

Affidavit, a statement reduced to writing, and sworn or affirmed to before some officer who has authority to administer an oath. An affidavit should refer to the cause in which it is made. The common-law rule is that it must contain the title of the cause. The place where the affidavit is taken must be stated, to show that it is taken within the officer's jurisdiction. The affiant must sign the affidavit at the end. It is necessary that the officer signing the jurat should append his official title.

An affidavit should also describe the affiant sufficiently to show that he is entitled to offer it, for instance that he is a party, or agent or attorney of a party to the proceeding. This matter must be stated, not by way of recital or as a mere description, but as an allegation in the affidavit.

Affidavit of Defense.— A statement made in proper form that the defendant has a good ground of defense to the plaintiff's action upon the merits.

Affidavit to Hold to Bail.— An affidavit which is required in many cases before a person can be arrested.

Affiliation is a species of adoption which exists in some portions of France and in other European States. The person affiliated succeeds equally with other heirs to the property acquired by the deceased to whom he had been affiliated, but not to that which he inherited. See ADOPTION.

As to orders of affiliation in bastardy proceedings, see BASTARD.

Affine Transformation, a-fīn', in geometry, a transformation by means of which every point in a plane receives a displacement whose direction is parallel to a given fixed straight line called the axis of affinity, and whose magnitude is proportional to the distance of the given point from that axis. The affine transformation is projective; that is, it transforms every straight line into a straight line.

Affinity. In law, the connection existing in consequence of marriage between each of the married persons and the kindred of the other. By the marriage one party thereto holds by affinity the same relation to the kindred of the other that the latter holds by consanguinity; and no rule is known to us under which the relation by affinity is lost on a dissolution of the marriage more than that by blood is lost by the death of those through whom it is derived.

Affinity is distinguished from consanguinity, which denotes relationship by blood. The degrees of affinity are computed in the same way as those of consanguinity.

In Chemistry.— The tendency manifested by certain substances to unite with one another so as to produce new combinations, chemically different from the primitive ones. The word was originally applied in this sense in the belief that some obscure and undiscovered «affinity» or relationship existed between the combining substances; but it now appears probable that the contrary is more nearly true, and that the tendency toward combination is strongest, generally speaking, between bodies that are quite dissimilar; though it is impossible to lay down any fixed rule of this simple kind. The modern theory of chemical affinity is too elaborate to be treated adequately under a single heading. See CHEMICAL AFFINITY; DISSOCIATION; ELECTROLYSIS; EQUILIBRIUM (CHEMICAL); MOLECULAR THEORY; SOLUTION.

Affirmation, the act of affirming, in the sense of solemnly declaring in a court of law that certain testimony about to be given is true. Also, the statement made. First the Quakers and Moravians, who objected on conscientious grounds to take oaths, were allowed to make solemn affirmations instead; now everyone objecting to take an oath has the same privilege; but, as is just, false affirmations, no less than false oaths, are liable to the penalties of perjury.

Affre, Denis Auguste, afr', dė-nē ō-güst, French ecclesiastic: b. 27 Sept. 1793; d. 27 June 1848. From his prudent and temperate character he was made Archbishop of Paris by Louis Philippe's government in 1840. Though not yielding blind submission to all its measures, he abstained from offensive opposition; and when a republic was proclaimed in 1848 he kept aloof from political strife, but displayed earnest

zeal for the public welfare. During the June insurrection he climbed on a barricade in the Place de la Bastille, carrying a green bough in his hand, as a messenger of peace; but he had scarcely uttered a few words when the firing recommenced, and he fell mortally wounded, to die next day. He wrote several theological works and one on Egyptian hieroglyphics.

Afghanistan, «Afghan-land,» Asia, a country lying between Persia W. and India and its N.W. frontier tribes E., with the latter and Baluchistan S., and Russia, Bokhara, and the Pamir region N.; extending from lat. 29° to 38° 30′ N. and lon. 61° to 75° E. Area, as defined N. 1885 and S. 1893, about 215,000 sq. m.; length E. to W. about 560 m., breadth about 450. Pop. estimated toward 5,000,000. The chief political divisions are Afghan Turkestan, Kafiristan, and Badakhshan, with part of the Pamirs turned over to it by the other powers: Kabulistan, of which Kabul is the heart, and including Ghazni and Jalalabad; and Herat. There are also independent khanates, and wild tribes which belong to nothing but the semi-enforceable sway of the amir.

Topography.— Afghanistan consists chiefly of lofty, bare, uninhabited table-lands, ranges of snow-covered mountains, and deep ravines and valleys. Many of the last are well watered and very fertile, but about four fifths of the whole surface is rocky, mountainous, and unproductive. The surface on the N.E. is covered with the lofty ranges of the Hindu-Kush, often 18,000 and sometimes exceeding 20,000 ft. high; the loftiest passes are above 12,000 ft.; and the road often passes along the base of mural precipices rising from 2,000 to 3,000 ft. It is an offshoot of the Himâlaya, parting the Oxus basin from the Afghan basins of the Kabul and Helmand; and sweeping S.W., at about lon. 68° (the Irak and Shibar passes) is prolonged by the Koh-i-Bâbâ, which breaks into several almost parallel branches inclosing the valleys of the Heri-Rud (Herat River) and Murghâb (Merv River), the two main ones known as Safed-Koh («white mountain»; there is another of the same name in the Kabul basin) and Siah-Koh. The E. is traversed by the Suleiman Mts., which extend to the Indus, and are united by a range called the Paghman Mts. with the Hindu-Kush above the Sirak Pass. The principal avenues of communication between Afghanistan and India are the famous Khyber (Khaibar) Pass, by which the Kabul River enters the Punjab; the Gumul Pass, also leading to the Punjab; and the Bolan Pass to the S., through which the route passes to Sind. Of the rivers, mostly in the centre of the country, the largest is the Helmand (old Etymander), which rises in the Koh-i-Bâbâ and Paghman Mts. between Kabul and Bamian, flows S.W. more than 400 m., till it enters the great Hamun or Seistan swamp; previous to which, however, its water is almost all drawn off for irrigation canals. About 45 m. below Girishk it receives the Arghand-âb, of about 235 m., rising in the Ghilzai country N.W. of Ghazni, and flowing past Kandahar. Next in importance are the Kabul in the N.E., an affluent of the Indus; and the Heri-Rud or Hari-Rud in the N.W., draining the Herat valley. The Amu-Daria or Oxus separates Afghanistan from Bokhara. The only lake worth mentioning (the Hamun being almost entirely in Persia) is the Ab-i-Stada, a shallow sheet about 12 m. in diameter, about 100 m. S.W. of Ghazni, at an elevation of some 7,000 ft.

Climate and Natural Products.— The climate is intensely hot in the lower regions and extremely cold in the upper, but fairly salubrious. The rainfall even in the rainy season is slight, and agriculture is maintained by irrigation canals, including a system called *karez,*— underground channels connecting the springs. The N. mountains are forested to about 10,000 feet; the others are bare. The commonest trees are pine, oak, wild olive, cypress, birch, walnut, and holly. Many indigo-yielding plants grow spontaneously on offsets of the Hindu-Kush, and asafœtida, a resinous gum, is an important product. In the plains the mulberry, tamarisk, acacia, willow, plane, poplar, and date palm, are found; and fine fruits in the greatest variety and abundance — especially apples, pomegranates, and peaches — grow wild. Wild animals are tigers, bears, leopards, wolves, jackals, hyenas, foxes, gazelles, wild asses, etc.

Agriculture, Manufactures, and Trade.— The cultivable soil in the valleys, a very small proportion of the whole area, is highly fertile under irrigation, but it is ill managed. In many parts two harvests are reaped annually: rice, corn, and millet occupying the land from spring to fall, wheat and barley, beans and peas thence to spring. The staple food of the people is wheat, that of cattle, barley. Other crops are grapes, tobacco, madder, and cotton, with some sugar-cane. Domestic animals are extensively bred: the chief are the horse, ass, and mule, the ox, sheep with large fine fleeces and enormous fat tails (famous in the «cinnamon stew»), the camel and dromedary. Manufactures are very scant, though some rugs, silks, sheepskins, camel- and goat-hair fabrics, etc., are sold; but the export of raw material is large, and forms a great trade with India and a considerable one with Bokhara, employing some 25,000 camels and many ponies, the use of wheeled vehicles being mostly impossible. The chief articles are wool (mostly sent to Karachi), raw silk, horses, dried fruits, madder, and asafœtida; rugs, silk goods, and rosaries also go out. The mineral deposits include all the great valuable kinds, but political conditions forbid their exploitation; some iron, lead, and sulphur are worked, however. Precious stones are found in the mountain country around Badakhshan.

Chief Towns.— The four leading places of Afghanistan are Kabul the capital, in the east, not far from the Indian border at the famous Khyber Pass, with some 70,000 people; Kandahar southwest of it, with 25,000, and Ghazni of 10,000 between them, all three on a great highroad that runs to Baluchistan, and forming a southeastern line of trade; and Herat of 30,000, in the extreme northwest, close to Persia. In Afghan Turkestan the chief place is Balkh; others are Andkhui, Akcha, Kunduz, Maimene, Tashkurgan, etc.

Peoples.— The Afghans proper, or Pathans, as the English call them, are the dominant race, forming perhaps three fifths of the whole. «Afghans» is the Persian name, their own being Pushtaneh or Pukhtaneh, and their language Pushtu or Pukhtu. The latter is Indo-European, and they are at bottom of that stock, though heavily mixed with the natives they

found there on invading the country (certainly centuries before Christ, as the Greeks found them there in the 4th); they claim Jewish descent, but this results from their Mohammedan religion (they are Sunnites), and occasional resemblances of feature, as they are not Semites. They are a finely built race, hardy, fierce, and turbulent, whose preference is plunder to live and fighting to enjoy. They force the inferior races to do the labor, and the land is cankered with blood-feuds. They are divided into many tribes, of whom the strongest are the Ghilzais of the east, and next the Duranis of the west and south (including the present amir and his predecessors of Dost Mohammed's family); strong also are the Yusufzais and Afridis on the borders of India. Among the others are the Swatis, Waziris, Kakars, and Kostis. There are also races of non-Afghan blood in Afghanistan: the Hazaras, a Mongol race living chiefly in the northwest; the Jats and Aimaks, Mongol; the Tajiks, believed to be a remnant of the aboriginal population and akin to the Dravidians of India; the Hindkis, an Indian race living in the southwest; the Kizilbashes, Persianized Turks; etc.

Government and Society.— There is a fair code of laws: from the nature of Afghan society the real law is that of the strongest, tempered by the responsibility of governors not to let society dissolve altogether from absence of justice. The ruler is a hereditary absolute monarch called the Amir, whose power among so fierce a feudal Oriental aristocracy is what he can enforce, which is very little unless he is a man of great abilities and firmness like the late Abd-ur-Rahman. Says a recent writer, « Like most monarchs, he rules not as he will but as he can, and the mantle of his authority covers the most turbulent race under the sun.» This is so even among the accessible peoples with a relatively civilized development of society: while there are many outlying tribes and chiefs who do not acknowledge his power, and can only be coerced into an appearance of submission by military force, as those of Kafiristan which Abd-ur-Rahman had but lately cowed at his death. These tribes furthermore are fanatical Mohammedans, which is always a fighting religion. Those which border on India, as the Afridis (whose position at the Khyber Pass, which must be kept open for a clear road to Kabul, makes it needful to hold them in with a strong hand), are counted as under British control rather than that of the amir, who besides receives an annual subsidy of 1,800,000 rupees (formerly 1,200,000), or about $630,000, from the Indian government, to enable him to maintain an efficient army and good order. Every eighth man is nominally subject to draft for military service; but the actual army is about 60,000, the detachments around Kabul, Kandahar, and Herat, and in Afghan Turkestan, numbering 37,000 foot and 7,000 horse, with 360 guns. At Kabul is an arsenal, also an ammunition factory and a mint having English machinery and supervision. The revenue is from tithes on produce, and naturally varies with the harvests. The money of account is the rupee (about 35 cents). Education is conducted by Mohammedan schools: of its nature a not unfair description may be found in Count Gobineau's 'History of Gamber-Ali,' in his 'Nouvelles Asiatiques' (Englished as 'Romances of the East').

History.— The first invasion of Indo-Europeans is before history. The country was subjugated after a fashion by Alexander the Great, who founded Herat (as Alexandria Arion), most likely Kandahar, and either Kabul or a colony near it. The Seleucid empire had no actual hold over it; the Romans lost even its nominal control to the Parthians and the later Persian empire; and the Saracens took it after their conquest of Persia. With the break-up of the Bagdad caliphate the Samanide dynasty possessed it, till overthrown in turn by the Ghaznevide, who held it till their downfall in 1183. Jenghiz Khan conquered it in the middle of the 12th century, and Timur late in the 14th; in 1504 Baber or Babar, the founder of the « Mogul » dynasty in India, had Kabul for his first capital, and Afghanistan became part of the great Afghan-Hindu empire, and remained a part of it while the Mogul dynasty kept its strength. In 1722 the Afghans raided Persia under one Mahmud, and permanently crippled Ispahan, which they captured; but in 1738 Nadir Kuli of Persia, later Nadir Shah (q.v.), retaliated and conquered Afghanistan. In 1747 he was murdered; Ahmed Shah, one of his generals, obtained the sovereignty of Afghanistan, and became the founder of the Durani, the first Afghan dynasty, which lasted about 80 years. At the end of that time Herat was all that remained in the hands of a Durani sovereign, while Dost Mohammed Khan, the ruler of Kabul, had acquired a preponderating influence in the country. He was desirous of gaining the assistance of the British against Persia; but believing that he was meditating treachery against them they resolved to dethrone him and restore Shah Shuja, a former ruler. In April 1839 a British army under Sir John Keane entered Afghanistan, and after overcoming some slight resistance entered Kabul and placed Shah Shuja on the throne. A force of 8,000 was left to support the new sovereign, and the rest of the army returned to India. Sir W. Macnaghten remained as envoy at Kabul, with Sir Alexander Burnes as assistant envoy. The Afghans were by no means content with the new state of affairs, however. A widespread conspiracy was organized, which came to a head on 2 Nov. 1841, when Burnes, Macnaghten, and a number of British officers, besides women and children, were murdered. The other British leaders were disheartened and paralyzed, and a treaty was made with the Afghans,— at whose head was Akbar, son of Dost Mohammed,— by which the former agreed to withdraw the forces from the country, while the latter were to furnish them with provisions and escort them on their way to Jalalabad. On 6 Jan. 1842, the British left Kabul and began their disastrous retreat. The cold was intense, they had almost no food — for the treacherous Afghans did not fulfil their promises — and day after day they were assailed by bodies of the enemy. By the 13th, 26,000 persons, among whom were many camp-followers, women and children, were destroyed. Some were preserved as prisoners, but only one man, Dr. Brydon, reached Jalalabad with the dismal news.

Jalalabad, in which Gen. Sale was stationed with a small force, was soon after besieged by

Akbar; but on the approach of Gen. Pollock, who had forced his way through the Khyber Pass with a fresh army from India, the Afghan forces withdrew. After joining his forces with those of Gen. Nott, who had meanwhile maintained himself in Kandahar and had taken Ghazni, Gen. Pollock entered Kabul and soon finished the war, though not without some hard fighting. Dost Mohammed again obtained the throne of Kabul and acquired extensive power in Afghanistan. He joined with the Sikhs against the British; but in 1855 he made an offensive and defensive alliance with the latter, which he renewed in 1857. He died in 1863, having nominated his son Shere Ali his successor. He entered into friendly relations with the British, and this state of matters continued till 1878; when, the amir having repulsed a British envoy and refused to receive a British mission (a Russian mission being meantime at his court) war was declared against him, and the British troops entered Afghanistan (November 1878). They met with comparatively little resistance; the amir fled to Turkestan, where he soon after died; and his son Yakub Khan, having succeeded him, concluded a treaty with the British (at Gandamak, May 1879), in which a certain extension of the British frontier, the control by Great Britain of the foreign policy of Afghanistan, and the residence of a British envoy in Kabul, were the chief stipulations.

Not long after this settlement, however, the British resident at Kabul, Sir Louis P. Cavagnari, and the other members of the mission, were treacherously attacked and slain by the Afghans, and troops had again to be sent into the country. Kabul was again occupied, and Kandahar and Ghazni were also taken; while Yakub Khan was sent to imprisonment in India. In 1880 Abd-ur-Rahman, a grandson of Dost Mohammed, was recognized by Great Britain as amir of the country. The occupation of Merv by Russia in 1881, and the subsequent continuous pushing forward of the Cossack outposts toward Herat and the south, now began to be seriously considered by the British as menacing India. After some negotiations between the two governments it was arranged that an Anglo-Russian commission should be constituted to settle the frontier between Afghanistan and Russian territory. In the meantime, however, the Russian troops were advancing; and in 1885 they reached Penjdeh, where they came into conflict with a body of Afghans. For a time war seemed imminent between Great Britain and Russia; but it was at last settled that the boundary line extending from the Heri Rud to the Oxus should run so as to exclude Penjdeh, but include Meruchak in Afghanistan, following the Oxus east from about Khojah Saleh to Lake Victoria, north of Chitral. The boundary between Afghanistan and British India was long uncertain; but in 1893 an arrangement was come to between the amir and Sir Mortimer Durand. The boundary then agreed on was demarcated shortly afterward and is so drawn as to leave Chitral, Bajaur, Swat, Chilas, and Waziristan to Great Britain, while Afghanistan is given the territories of Asmar, Birmal, and Kafiristan. The Amir's annual subsidy was also increased from 12 to 18 lacs of rupees, and restrictions on the import of arms, etc., were removed. Abd-ur-Rahman proved himself a vigorous ruler and the steady friend of Great Britain, and did much under the guidance of Englishmen to civilize his subjects and develop the resources of his country. He was for a time suspected of secretly assisting the frontier tribes in their revolt in 1897; but he later gave unmistakable proof of his loyalty. He died in Kabul, 3 Oct. 1901, and his eldest son Habibullah-Khan succeeded him.

A Fortiori, an argument derived from what is stronger; an argument more potent than that which has just before been employed. When in Euclid it is reasoned, for example, that much more then is the angle B D C greater than the angle B C D, the use of the words much more implies that the *à fortiori* argument is used.

Africa, third in size of the five continents, with a continental area of 11,500,000 sq. m. and islands of 239,000 more, has the Mediterranean N., the Atlantic W., the Red Sea and Indian Ocean E., the Antarctic Ocean S.; and lies nearly due S. of Europe and S.W. of Asia. It extends from lat. 37° 20′ N. to 34° 51′ S., and lon. 17° 32′ W. to 51° 16′ E., being nearly equal in length and breadth from its extreme points: from Cape Blanco in Tunis to Cape Agulhas in Cape Colony is nearly 5,000 m.; from Cape Verde in Senegal to Cape Guardafui in Somaliland about 4,600. The N. section, however, has an average breadth nearly double that of the S., owing to the great N. projection of the upper part, the W. coast taking a sudden inward turn and facing S. for nearly 20° of longitude, forming the Gulf of Guinea, its greatest indentation.

General Topography.— From its junction with Asia at the Isthmus of Suez, the N. coast runs W. by a little N. to the Strait of Gibraltar; its nearest approach to Europe, whose Mediterranean shore it faces, and whence for many centuries it derived its principal civilization. The chief indentation is that forming the Gulfs of Cabes and Sidra. From the Isthmus S. the coast runs somewhat S.E. parallel to Arabia, separated by the long narrow expanse of the Red Sea; further S. it projects well to the E., overlapping the S. coast of Arabia and again running nearly parallel to it, the two forming the Strait of Bab-el-Mandeb and the Gulf of Aden. From the terminus of this projection at Cape Guardafui, the coast trends S.W. with slight undulations to the S. extremity of the continent. About midway, separated from the mainland by the Mozambique Channel, 250 m. wide, lies the great island of Madagascar. Save those named, Africa has no great indentations, and the coast line is very small relatively to its size: about 16,000 m., a fifth less than that of Europe absolutely, and between one fourth and one fifth as great relatively. The S. extremity presents to the Southern Ocean a coast line of nearly 400 m. excluding indentations, compendiously known as «the Cape,» first doubled by Bartholomew Diaz and Vasco da Gama. Its principal indentations are Algoa Bay and False Bay. The islands belonging to Africa are not numerous, and except Madagascar none of them large. In the Atlantic Ocean there are Madeira, the Canaries, the Cape Verde Islands, the Bissagos, the islands off the coast of Guinea, Fernando Po, St. Thomas, Annobon, etc., Ascen-

sion Island, St. Helena, and Tristan d'Acunha; in the Indian Ocean, Sokotra, Zanzibar, Comoro Isles, Madagascar, Mauritius, Réunion, with their dependencies; and some small islands in the Southern Ocean.

Northern Africa.— The interior of Africa forms two great divisions nearly corresponding with the external diversity of form already indicated. The N. section has its greatest extension from E. to W., the S. from N. to S. The N. division lies for the most part above the sixth degree of N. latitude, extending from the Atlantic on the W. to the Somali coast and the Red Sea on the E. Its principal feature is the Sahara or Great Desert, which is inclosed on the N. by the elevated plateau of Barbary and that of Barca, on the E. by the Nile valley, on the W. by the Atlantic Ocean, and on the S. by the Niger and the countries of the Sudan. The N. coast region (plateau of Barbary) is traversed by the Atlas system and its continuations, rising to the height of 13,000 ft. or even more. Exclusive of the mountains it has an elevation of from 1,500 to 3,000 ft. From Barca, where the former level prevails, it descends gradually toward Egypt. The character of the desert, though sufficiently inhospitable, is much less uniformly monotonous than till recent researches it was commonly reputed to be. Instead of an undeviating sandy plain irregularly interspersed with speck-like oases it contains elevated plateaux and even mountains with more or less permanent streams, and habitable valleys which lose themselves in the vast low-lying tracts of sand with which the more elevated regions alternate. The desert itself is furrowed with *wadis* (dry river-beds) radiating in all directions; while under the sand collections of water have been found, which by means of artesian wells have been turned to account by the French in their dependency Algeria. A considerable nomadic population is thinly scattered over the habitable parts of the desert, and in the more favored regions there are settled communities. (See SAHARA.) To the S. of the Sahara, and separating it from the plateau of southern Africa, a belt of pastoral or steppe country extends across Africa. This region has received the general name of the Sudan, and includes the countries on the Niger, around Lake Tchad, and E. to the elevated region of Abyssinia.

Southern Africa.— From Lake Tchad the country begins to rise till below the 10th degree of N. latitude, where the edge of the elevated plateau of high or southern Africa begins. This division of the continent is, as far as known, completely surrounded, at a distance of 50 to 300 miles from the coast (which is usually low but rising inland), by what look like ranges of mountains varying in breadth and height; but which are really the escarpment of a table-land, or series of table-lands, of considerable elevation and great diversity of surface and direction, having hollows filled with great lakes rivaling those of America in extent, and terraces over which the rivers break themselves in falls and rapids. The S. division has, like the N., a desert region — the Kalahari desert — but it is of small extent compared to the Sahara. In some respects it resembles the Sahara, but possesses more vegetation. The mountains which inclose the S. table-land are mostly much higher on the E. than on the W.; and the slope of the land and the flow of the principal rivers, with the exception of the Zambesi, is from E. to W. The E. edge of the plateau reaches its highest elevation and greatest extent in the mountainous country of Abyssinia, with heights of 10,000 to 14,000 or 16,000 ft. From this the system extends N. in detached ranges or occasional elevations between the valley of the Nile and the Red Sea, with gradually diminishing height to the very delta of the Nile. The E. edge of the Abyssinian plateau presents a steep unbroken line of 7,000 ft. in height for several hundred miles. This line of elevation extends S. toward Lakes Rudolf and Stefanie, and thence in a narrow belt and at a lower average level to the N.E. of the Victoria Nyanza; it then proceeds in a S. direction to Kilima-Njaro, beyond which the plateau merges into the Paré Mts. in the neighborhood of the Pangani River. Immediately to the S. of Lake Rudolf, Mount Nyiro rises to a height of 10,000 ft.; Mount Elgon, to the N.E. of Victoria Nyanza, 14,100 ft.; Mount Kenia, 18,370 ft.; Kilima-Njaro, 19,600 ft.; Mount Meru, to the W. of Kilima-Njaro, 14,000 ft. The general level of the plateau between Mount Kenia and the lake is from 5,000 to 7,000 ft. To the W. of Victoria Nyanza, between Lakes Albert and Albert Edward, Mount Ruwenzori rises to a height of 18,000 ft., and the active volcanic Kirunga Mts., S. of Lake Albert Edward, to 13,000 ft. All these mountains are volcanic in origin, and between Kilima-Njaro and the lake signs of volcanic activity are still visible. The central plateau reaches its greatest average height, over 4,000 ft., in the region embracing the Lakes Victoria, Tanganyika, and Nyassa; it forms a broad belt reaching close to the E. coast, and in an equally broad belt extends from Lake Nyassa to the W. coast. Above this are numerous detached heights, like the Rubeho Mts., W. of Zanzibar, the Livingstone Mts. around the N. of Lake Nyassa, and the Mlanje heights S. of that lake; Mount Mlanje being 9,680 ft. S. of the Zambesi occur the Mashona and Matoppo highlands, rising in places to from 5,000 to 7,000 ft. Immediately to the S. of the Middle Limpopo a series of mountains begins which, under various names — Zoutpansberg, Libombo, Drakensberg, Compassberg, Schneeberg, etc.— extends along the E. and S. coast, and N. to some distance beyond Cape Town. In Natal these rise to 10,000 and 12,000 ft., and in Cape Colony to 7,000 and 8,000 ft.; the interior plateau averaging about 4,000 ft., but falling to a lower level in the Kalahari desert. Between the Orange River and the Kunene, and the latter river and the Kongo, the escarpment continues, rising in places to 6,000 and 8,000 ft. The general level lowers considerably as the Kongo is reached. The low coast region extends some distance into the interior along this part of the W. coast, the descent from the interior plateau giving rise to the cataracts which so seriously interrupt navigation on the lower Kongo. On both sides of the middle Kongo extends a considerable area which sinks from the generally high level of the interior to an average of only about 1,000 ft. From the Kongo and Kameruns the general level of the coast plateau is broken by the Crystal and other mountains rising to 3,000 and 4,000 ft., culminating in the Kameruns Peak, a volcanic mountain rising to 13,000 ft.

On the S. of the Benue, in the Atlantika group, and between the Benue and the Niger, we find a broken mountain group with heights of from 6,000 to 10,000 ft.; while in the interior N. of the Gulf of Guinea there is a broad plateau, beginning at various distances from the coast, extending across the upper Niger, and rising to 2,000 and 3,000 ft., with irregular ranges rising at places to from 5,000 to 7,000 ft. The Kong Mts., in the region where the Niger has its sources, as a range do not exist. As the middle Niger is approached the general level lowers to that of the Sahara, while N. the low coast region extends far into the interior till the Atlas is reached.

Rivers.— The Nile is the only great river of Africa which flows to the Mediterranean. It is now known to receive its waters primarily from the country drained by the great lakes, the Victoria Nyanza, the Albert Nyanza, and the Albert Edward Nyanza, and especially from the Victoria Nyanza, which itself receives numerous streams. The Victoria Nile connects the Victoria and the Albert Nyanza; and on leaving the latter the river flows in a winding course, of which the direction is almost due N., without further lake expansion, to the Mediterranean. In descending from the lake elevations (of the Victoria 3,900, of the Albert Edward 3,200 ft., the latter connected by the Semliki River with the Albert 2,300 ft.) it makes, both between the lakes and in its subsequent course, numerous falls. Those in upper Egypt are known as the Cataracts. Between lat. 5° and 10° N., under the name of Bahr-el-Jebel, it receives numerous tributaries, mostly from the country to the S. and W.; the principal on the left bank being the Bahr-el-Ghazal, on the right the Sobat. After this it takes the name of the White Nile, and receives through the Bahr-el-Azrek and Atbara, or Blue Nile and Black River, the drainage of Abyssinia. The Atbara brings the mud which forms so precious a deposit in Egypt. After this the Nile flows for 1,200 m. to the sea without receiving a tributary. Altogether it drains an area of more than 1,000,000 sq. m. The Indian Ocean receives numerous African rivers, most of which are short, being the drainage merely of the external slopes of the escarpment of the interior plateau. Among the most considerable rivers on this coast are the Jub, which is formed by several streams rising in the border slopes near Abyssinia, is navigable with difficulty to Bardera, and enters the ocean at the equator; the Webi Shebeli, formed by streams rising on the S.E. slopes of Abyssinia, and losing itself in the sands on the coast near the mouth of the Jub; the Tana from Mount Kenia discharging at Witu; the Sabaki S. of the Tana; the Rufiji or Lufiji; the Rovuma, which flows from the mountains E. of Lake Nyassa; the Beira; and the Limpopo or Crocodile, which enters the ocean N. of Delagoa Bay. The only great river flowing from a distant point of the interior which breaks the mountain barrier of the E. is the Zambezi, which has its embouchure between the Beira and Rovuma. It is the fourth in size of the continent. It drains a large part of the great tract of pastoral country S. of the equatorial region. Several streams coming from the swampy plateau on the borders of Lunda and the Garenganze country unite to form the Zambezi, the principal being the Liba from the S.W. edge of the Garenganze country. In its middle course it is joined by the Kafue and Loangwe from the N. and the Shire from Lake Nyassa, and by the Chobe and some smaller streams from the S. Below the Chobe are the Victoria Falls, one of the greatest cataracts in the world; from which the river flows in a semicircular course to the ocean, breaking through the Lupata Mts., and discharging by several mouths, the most navigable of which is the Chinde. The river is navigable by vessels of some size to the Karoabassa Rapids beyond the Shire, but above that only by boats and canoes. The drainage area of the Zambezi is 514,000 sq. m.

Of the Atlantic rivers, the Senegal, Gambia, and Niger have their origin in the mountains near the coast of Senegambia. The Senegal flows in a N. and W. direction, its volume varying much according to the season. In the rainy season it is navigable for 500 to 700 m., in the dry season for about a fourth of that distance. The Gambia takes a winding course to the W., and is navigable for about 400 m., nearly its whole extent. The greatest of these rivers, the Niger, rising in the inner slope of the same mountains, flows N.E. to Timbuktu, whence it turns first E. and afterward S.E., receiving the Sokoto, to its junction with the Benue, which comes from the mountains S. of Lake Tchad. The upper part of the Niger is called the Joliba, and is flanked by several great swampy lakes; it afterward acquires the name of Quorra or Kawarra. In the N. part of its course it touches on the great desert. It is navigable for light vessels above Timbuktu. Between the Sokoto and the Benue it is interrupted by shoals and rocks to below Boussa. From the junction it flows due S. to the ocean, where it forms a wide alluvial delta, and enters by a number of mouths, the most distant of which are 200 m. apart. The main channel is called the Nun. The drainage area of the Niger is 810,000 sq. m. The Kongo, the second in extent of basin and the greatest in volume of the African rivers, flows from different slopes of the same watersheds as the Zambezi. Its identification with the Lualaba, the great stream discovered by Livingstone in the centre of the continent, was established by Stanley in 1876–7, this enterprising traveler having descended the river to the Atlantic from a point in the interior W. of Tanganyika. The Lukuga, the outlet of Lake Tanganyika, discovered by Cameron, is a tributary of the Lualaba. The Chambeze, which rises in the mountains between Lakes Nyassa and Tanganyika, is the remotest source of the Kongo system. It falls into Lake Bangweolo, from which it issues under the name Luapula, and flows N. to Lake Mweru; from the N. side of this lake issues the Lualaba, which passes through a magnificent series of lake-like expansions and receives numerous tributaries. Below Stanley Falls it receives the Lomami, and above Stanley Pool the Kwa, which is formed by the junction of the Kasai-Sankuru system with the Lukuallu or Kwango. Other tributaries come from the S., and in the N. it is fed by the Ubangi, which, under the name of the Wellé-Makua, comes from the water-parting between the Nile and Kongo systems. The total length of the Kongo is about 3,000 m., and its drainage area 1,450,000 sq. m. Unlike most of the African

rivers, the mouth of the Kongo forms an estuary. It is estimated to pour into the ocean a larger body of water than the Mississippi. The Kwanza rises in the Mossamba Mts., and curves N.W. to the ocean. Like most African rivers, its upper course is interrupted by cataracts, and its mouth closed by a bar. The Kunene rises on the opposite side of the same watershed, and flows S.W. to the Atlantic. From it S. to the Orange River follows a dry belt, through which no considerable river flows to the sea. The Orange, though it rises near the E. coast, and flows nearly across the S. part of the continent, passes for the greater part of its course through a desert region, receiving no tributaries, and is a shallow stream. Its headwaters, the Vaal and the Nu Gariep, rise on opposite slopes of the Drakenberg Mts., and flow to their junction round opposite sides of the Orange River Colony. The Great Fish River, which drains Great Namaqualand, enters the Orange River near the termination of its course.

The rivers which reach the ocean do not account for the whole drainage of Africa. There are two great and numerous smaller tracts from which no large river reaches the sea. The two great areas of internal drainage correspond with the two great deserts. That of the N. desert is estimated at 4,000,000 sq. m. As already indicated, it is furrowed with water-courses in every direction, which lose themselves in the sand. The Bahr-el-Ghazal, which is usually dry, but intermittently flows out of Lake Tchad, terminates in a salt lagoon on the border of the desert to the N. of the lake. In the S. the Zuga or Botletle, which forms the outlet of Lake Ngami, in the Kalahari desert, loses itself in salt lagoons at greater or less distance, according to the supply of water. A region of inland drainage, with salt lagoons, also exists between the Victoria Nyanza and the coast range of mountains. In the low coast land E. of Abyssinia the Hawash River loses itself in the sands before reaching the sea; and the Webi, as already stated, which flows S. from the Somali Peninsula to near the equator, likewise terminates in a salt lagoon on the border of the ocean. The Omo flows into the N. end of Lake Rudolf.

Lakes.— The only lake of considerable extent N. of lat. 5° N. is Lake Tchad, an enormous flooded swamp. Lake Tana in Central Abyssinia, the salt Lake Asal in the E., and Lakes Dembel and Abayo in Gallaland, are comparatively small. Between 5° N. and 15° S. is a series of lakes forming one of the most striking features of the continent. Almost in a line, beginning in the S., are Lakes Nyassa, Tanganyika, Lifu, Albert Edward, Albert, all lying in more or less elongated rifts or gorges. The series is continued by Lakes Rudolf (salt) and Stefanie in the N.E., and, according to some authorities, by the ancient lake now the Red Sea, and by the Dead Sea in Palestine. The great Victoria Nyanza, which touches the equator on the north, is of a different type, as are Lake Bangweolo (another flooded swamp) on the S. of Tanganyika, and Lake Mweru in the N. of Bangweolo. Lake Rikwa or Leopold, between Nyassa and Tanganyika, is partly of the rift type, while Lake Ngami in the Kalahari region is a swamp which sometimes dries up. Lake Leopold II. and Lake Malumba are attached to the lower Kongo. Lake Dilolo is in the swampy region forming part of the watershed between the Kongo and the Zambezi. There are numerous salt lagoons in the N. portion of the Sahara.

Climate.— The climate of Africa is mainly influenced by the fact that, except the countries on the N. and S. coasts, it lies almost entirely within the tropics. The equator, as already observed, cuts it nearly through the middle, so that it belongs in latitudinal, though unequally in longitudinal extension, to the N. and S. tropics. It is the only continent which extends unbroken from the N. to the S. tropics, and is consequently the hottest of all. The two sections N. and S. of the equator have, as has already been observed, in some respects a very considerable resemblance in their general features, the chief modifying circumstances being the greater elevation and the smaller longitudinal extension of the southern division, which, by bringing it more within the influences of the ocean, tends to modify its climate.

In the belt immediately under the equator, both N. and S., vegetation is intense and rain abundant. For about 10° N. and S. we find true tropical forests, mainly to the W. of the great lakes, on the middle and upper Kongo and its affluents, and along a belt of the W. coast in the Niger region. To the E. of the great lakes, where the rainfall is not so abundant, are considerable areas of poor steppe and scrub country, and generally over the tropical region the trees are scattered and the country more park-like than forestal. Animal life, from herds of elephants to innumerable swarms of insects, abounds in these luxuriant regions. To the N. and S. of the equatorial belt, as the rainfall diminishes, the forest region is succeeded by open pastoral and agricultural country. This pastoral belt extends, in the N., across the Sudan, from Senegambia to Abyssinia; on the S., from Angola and Benguela to the Zambezi. This is followed by the rainless regions of the Sahara on the N. and the Kalahari desert on the S., extending beyond the tropics, and bordering on the agricultural and pastoral countries of the N. and S. coasts, which lie entirely in the temperate zone.

The winds and rains in Africa are chiefly produced by the successive exposure of the various intertropical belts to the vertical rays of the sun. The monsoons of the Indian Ocean exercise the principal modifying influence. From March to September the S.W. monsoon blows from Africa to Asia, and during the remaining months the N.E. monsoon blows toward the African coast. The indraught of air charged with moisture, at the seasons when the sun is overhead, produces the rainy seasons within the tropics, and as the incessant rarefaction of the air by heat continually draws in fresh supplies, the rainfall is on the whole abundant, varying from 50 to 100 inches in the region between 10° N. and the Tropic of Capricorn. In a patch on the Gulf of Guinea the 100 inches is exceeded, though in Somaliland there are almost rainless patches. Near the tropics, to which the sun comes only once a year, there is only a single rainy season, while in the central part of the zone, which the sun traverses twice in his passage between the tropics, there are two distinct rainy seasons, a greater and a less, according as

the wind is in a direction which brings more or less moisture, except in some places in the interior, where the two rainy seasons are so protracted as to blend into one, lasting, as in the Manyuema country, from September to July, or in some other parts even longer. The rainy season usually begins soon after the sun has reached his zenith, but on the E. coast the monsoon charged with the moisture of the Indian Ocean brings it earlier. In the deserts, as already observed, there is hardly any rain; and this applies also to Egypt, which but for the Nile would be no better than the Sahara. The chief cause of the rainlessness of the deserts is the direction of the winds, which causes the chief moisture-bearing currents to pass, before reaching them, over hot and thirsty regions which deprive them of their moisture; and especially the mountain screens which intercept the moisture of the winds both from N.E. and S.W. Another cause is the want of elevated regions to attract the moisture actually contained in the atmosphere, as in the higher regions of the desert periodical rains do occur. The high mountains of the E. plateau and the intervening tropical regions deprive the N.E. monsoon of all its moisture before it reaches the Kalahari Desert. Hence the apparently anomalous circumstance that the greatest heat is found after the equatorial region is passed. The rapid radiation of heat in the desert causes a very great fall of temperature after the sun is down, so that sometimes frosts are generated, and this in some measure supplies the want of rain by condensing the moisture in dew. In the desert, too, scorching winds are generated, those of the N. afflicting Egypt and the countries on the Mediterranean coast. The hottest part of the Sahara is in Nubia, where the Arabs say the soil is like a fire and the wind like a flame. The coasts of tropical Africa, especially the W. coast, where colonial settlements have been formed, have been found to have a deadly climate for foreigners.

Geology, Minerals.— The geology of Africa is still very little known. Very ancient crystalline rocks are found rising into mountain ranges and sometimes spread over large areas. Most of the rocks that overlie them belong to the older formations, so that the continent as a whole is supposed to be of very ancient date. The sands which cover so large an area are believed to be mainly of æolian origin, and not to have been formed by the action of water. The porous clay found so abundantly in west Africa is of comparatively recent date. The region around Tanganyika is of Jurassic origin. Around the great lakes are abundant evidences of enormous volcanic activity at no very remote date; and, as already mentioned, active volcanoes are not unknown. Tanganyika, according to recent views, may at one period have been connected with the sea. Salt is abundant, though often scarce from want of communication and working organization. Gold is found in abundance in southern Africa from the Transvaal region to the Zambezi, and a number of very productive mines have been opened in the Transvaal. Diamonds have been found in large numbers, and in apparently inexhaustible supply, on the Vaal River and its tributaries. In the southern central district, particularly the country of Katanga, iron and copper are found, and are worked in some districts in the countries bordering on the Lualaba. Copper is also found in Loanda, iron in Angola, and lead, tin, iron, and copper in Great Namaqualand; iron, copper, and coal are found in Natal.

Vegetation.— The centre of Africa possesses, as already mentioned, an exuberant tropical vegetation. The open pastoral belt at the extremities of the tropics is distinguished by a rich and varied flora. A special characteristic of the vegetation of the southern extremity of Africa is the remarkable variety, size, and beauty of the heaths, some of which grow to 12 or 15 feet and form miniature forests. Cycadaceæ and bulbous and orchidaceous plants, aloes, and other succulent plants, also abound. The baobab or monkey-bread tree, first discovered by Adanson in Senegal, is found from the Sudan to Lake Ngami, and palms of one variety or another are diffused over almost every part of Africa. The date palm is the special characteristic of the desert, to which it is peculiarly adapted, and there it forms the principal means of subsistence. It is also cultivated as a garden plant in the northern coast regions. This district as well as Egypt has an ancient celebrity for its fertility in grain. Wheat and maize are cultivated, fruit trees also abound, and groves of oranges and olives distinguish the landscape. The castor oil plant, the fig tree, the dwarf palm, and the lotus, formerly an important article of food, are here characteristic forms. The common oak, the cork oak, and the pine form the staple, and the cypress, myrtle, arbutus, and fragrant tree heaths the ornaments of the woods. The pastoral tropical belt presents a different order of vegetation. Besides the baobab, the cabbage palm, the oil palm, the wax palm, the shea butter tree, the cotton tree, the African oak, and the mangrove here prevail; rice and maize are cultivated; the principal fruits are the banana, papaw, custard apple, lemon, orange, and tamarind. India-rubber plants are found in various forms, as trees and as climbing plants, in abundance both in east and west tropical Africa. The prevalent plants of this district are also found in the fertile parts of Nubia. To the northeast of this region frankincense, myrrh, cinnamon, and cassia abound. The coffee plant is a native of the southern Abyssinian region, and also of western tropical Africa, where it forms thick woods. This plant is supposed to have been transported from Africa to Arabia. Abyssinia, though coffee and spices are native products, possesses generally, from its elevation, the vegetation of a temperate region. The swamps of the tropical region abound with papyrus. The cassava, yam, pigeon-pea, and ground-nut are cultivated as bread plants.

Animals.— The fauna of Africa is extensive and varied, and numerous species of mammals are peculiar to the continent. According to a scientific view of the geographical distribution of animals, the north of Africa belongs to the Mediterranean sub-region, while the rest of the continent forms the Ethiopian region. Africa possesses numerous species of the order *Quadrumana* (apes and monkeys), all of which are peculiar to it. They abound especially in the tropics. The most remarkable are the chimpanzee and the gorilla. The lion is the typical carnivore of Africa. Latterly he has been driven from the coast settlements to the interior, where

he still reigns king of the forest. There are three varieties, the Barbary, Senegal, and Cape lions. The leopard and panther rank next to the lion among the carnivora. Hyenas of more than one species, and jackals, are found all over Africa. Elephants in large herds abound in the forests of the tropical regions, and their tusks form a leading article of commerce. These are larger and heavier than those of Asiatic elephants. The elephant is not a domestic animal in Africa as it is in Asia. The rhinoceros is found, like the elephant, in Middle and Southern Africa. Hippopotami abound in many of the large rivers and the lakes. The zebra and quagga were numerous in central and southern Africa, but the latter is said to be now entirely extinct. Of antelopes, the most numerous and characteristic of the ruminating animals of Africa, at least 50 species are considered peculiar to this continent, of which 23 used to occur in Cape Colony. The giraffe is found in the interior and is exclusively an African animal. Several species of wild buffaloes roam in the interior, and the Asiatic buffalo has been naturalized in the north. The camel, common in the north as a beast of burden, has no doubt been introduced from Asia. The horse and the ass are highly developed in the Barbary States. The cattle of Abyssinia and Bornu have horns of immense size but extremely light. In Barbary and the Cape of Good Hope the sheep are broad-tailed; in Egypt and Nubia they are long-legged and short-tailed. Goats are in some parts more numerous than sheep, especially in the Sudan and in Abyssinia. Dogs are numerous, but cats rare, in Egypt and Barbary. The former in the northern towns serve as scavengers. Bears and foxes are found only in the north. The birds of northern Africa are almost identical with those of the south of Europe and the Asiatic countries bordering on the Mediterranean. Many of the African birds are famed for the brilliancy of their plumage, such as the sun-birds, bee-eaters, rollers, plaintain-eaters, parrots, and kingfishers. The ostrich is found nearly all over Africa, but especially in the desert. A remarkable bird of southern Africa is the secretary-bird or serpent-eater, which renders great service to the inhabitants by killing serpents. Another peculiar bird of South Africa is the little honey-guide (q.v.), which points out the nests of bees. The whale-headed stork, remarkable for its enormous beak, may also be mentioned. Owls, falcons, eagles, and vultures are numerous. Water-fowl are abundant on the lakes and rivers, and there are many species of quails and partridges. One species of gallinaceous bird, the guinea-fowl, has been domesticated in other countries. Reptiles, owing to the dryness of the climate, are comparatively few. The largest is the crocodile, which abounds in the great rivers and tropical lakes. There are several species of venomous serpents, including the horned viper and the African cobra. The chameleon is common. The rivers and coasts abound with fish of numerous species, and some of them of the most brilliant coloring. Insects are numerous. Among the more troublesome species are the locust, tsetse, and white ant.

Inhabitants, Civilization, etc.— There is a marked distinction between the races in the north and east of the great desert and those in central Sudan and the rest of Africa and the south. The main elements of the population of north Africa, including Egypt and Abyssinia, are Hamitic and Semitic, but in the north the Hamite Berbers are mingled with peoples of the same race as those of prehistoric southern Europe, and other types of various origins, and in the east and southeast with peoples of the negro type. The Semitic Arabs are found all over the northern region, and even in the western Sahara and central Sudan, and far down the east coast as traders. The Somalis and Gallas are mainly Hamitic. In central Sudan and the whole of the country between the desert and the Gulf of Guinea the population is pure negro — people of the black, flat- or broad-nosed, thick-lipped type, with narrow heads, woolly hair, high cheek-bones, and prognathous jaws. Scattered among them are peoples of a probably Hamitic stock. Nearly the whole of the narrow southern section of Africa is inhabited by what are known as the Bantu races, of which the Zulu or Kaffir may be taken as the type. The languages of the Bantu peoples are all of the same structure, even though the physical type vary, some resembling the true negro, and others having prominent noses and comparatively thin lips. The Bushmen of southern Africa are of a different type from the Bantu, probably the remains of an aboriginal population, while the Hottentots are apparently a mixture of Bushmen and Kaffirs. Scattered over central Africa, mainly in the forest regions, are pygmy tribes, who are generally supposed to be the remains of an aboriginal population. The bulk of the inhabitants of Madagascar are of Malay affinities. The total population is estimated at about 150,000,000.

As regards religion, a great proportion of the inhabitants are heathens of the lowest type. Mohammedanism possesses a large number of adherents in northern Africa and is rapidly spreading in the Sudan. Christianity prevails chiefly among the Copts of Egypt, the Abyssinians, and the natives of Madagascar, the latter having been converted in recent times. Elsewhere the labors of the missionaries have been attended with promising success. Over a great part of the continent, however, civilization is at a low ebb, and in the Kongo region cannibalism is extensively prevalent. Yet in various regions the natives who have not come in contact with a higher civilization show considerable skill in agriculture and various mechanical arts, as in weaving and metal-working. Among articles exported from Africa are gold and diamonds, palm oil, ivory, wool, ostrich feathers, esparto, cotton, caoutchouc, etc. See paragraph *Commercial Conditions* at end of this article.

Languages.— The languages spoken on the continent may be divided into two great classes, those native to Africa and those brought in from outside: the former including the three great divisions of Negroid, Hottentot-Bushman, and Hamitic, the latter Aryan, Malay, and Semitic; and the latter again into the pure languages or *patois* of recent immigrants or traders, and those which have become naturalized by time and change into virtually native tongues themselves.

The first division of the extra-African tongues comprises: (1) Pure English in South Africa and Liberia, pure French in Algeria and the scattered trading settlements elsewhere. (2)

MARIBOU STORK (*Leptoptilus crumeniferus*) AFRICAN JABIROU (*Mycteria senegalensis*)

Four «creole» dialects: the Mediterranean «lingua franca» or trade jargon; the English creole or West African Kru-English; the Cape Verde Islands Portuguese creole; and the Boer and Hottentot Dutch creole. The last three are European in stock, but with much African phonic, inflectional, and syntactical mixture and influence. The second division includes the Malay or Malagasy of Madagascar, and the Semitic tongues of the northeast. These last are (1) Pure Arabic (the Latin of Africa, the universal language of social intercourse and trade wherever Mohammedanism prevails), including the Egyptian, Sudani, Maghreb, and Muscat dialects; (2) mixed, as the Abyssinian dialects, derived from the ancient Geez (q.v.), Tigré and Tigriña, Amharic (originally of southern Abyssinia, but now the chief tongue of the country), Harari of the Galla country, Gurague, etc. All these were brought in by Semitic invaders.

The native African stocks are classed in English books mainly according to the system adopted from Friedrich Müller by R. N. Cust in his ‹Modern Languages of Africa›; later German Africanists prefer that of Lepsius, the chief difference being on the relations of Bantu and Negro or Nigritic.

1. Negroid. This has three main divisions: (1) Bantu, a pure language. This immense group occupies, with enclaves of Hottentot-Bushman and Pygmy, the whole vast triangle from the Kamerun west and Zanzibar east down to the Cape, or pretty much all Africa south of the equator. All its components (for which see BANTU) have one grammar though different vocabularies; the greatest and perhaps purest representatives of it are the Zulus or Kaffirs, and their neighbors the Se-chuana. (2) Nigritic, Negro, or Sudan-Negro, between the Sahara and the equator. Ethnologically, the races speaking this group of tongues are the purest types of the Negro stock; but linguistically, they are only classed together from the utter impossibility of grouping them with any others, though Lepsius thinks them degenerated Bantu, — a conclusion scouted by others, the affinities being very faint. They are many and to all appearance totally unrelated, so diverse and peculiar are the idioms; some, however, think they show marked characteristics in common. They doubtless represent the oldest races on the continent, wandering in small hostile bands and changing their dialects almost from generation to generation, like all such petty camps with unfixed traditions and no general intercourse; and may well have scores or hundreds of «languages» among them with no traceable connection. (3) The Nuba-Fulah or Ful; sometimes called the Nilotic, from its main seat in the Nile valley from Nubia to the Albert Nyanza, and with isolated tribes farther out, as the Barea and Kunama on the northern border of Abyssinia, and the Masai and Oigob southwest. Others dispute the inclusion of the Fulah, considering it a tongue by itself; perhaps a mongrel, more likely a family as above, which has picked up some Hamitic words. The Dinka, Bari, and Shilluk are its chief families along the Nile, the Lur or Shuli and Madi being the last to the south; west of the valley it shades into the Nigritic chaos.

2. The Hottentot-Bushman. This is the language of the dwarf tribes, and its relations to others or itself are vigorously debated. Müller thought it represented two ethnological and linguistic divisions. Lepsius thinks it one, Bantu in race and Hamitic in language; but his conclusions are not accepted. Besides the main stock in southern Africa, this group includes the Pygmy dialects in central Africa: it is denied that they have kept their original languages, but this is true of many others, and the ethnological and linguistic problems have no necessary relation.

3. Hamitic. This includes (1) the Libyan or Berber dialects spoken across north Africa from the Canaries to Egypt — probably changed scores of times from top to bottom; (2) the ancient Egyptian, with the four dialects of its descendant Coptic (extinct save as the ritual language of the Coptic Church); (3) the non-Semitic or Kushite Abyssinian dialects (formerly called Punic, sometimes Ethiopic, which was more generally applied to Geez): as Bishari (see BISHARIN), the ancient Bedja, between Egypt and Abyssinia; Danakil (q.v.) or Dankali, native name Afar, between Abyssinia, Massowa, and Obok; Somali and Galla, in their countries; Agau (through Abyssinia, the users believed to be its aborigines, with dialects as Chamir, Quara, etc.); Saho, between Abyssinia and Adulis Bay; Kaffa, Kullo, etc., in the highlands south of Abyssinia. The Fulah group (see above) and the Haussas in Sokoto have some Hamitic admixture. These Hamite tribes are much mixed, geographically or more intimately, with Semitic and Negro tribes or elements.

«Equatorial» is a name given in 1889 by Müller to a group of Negro tribes S. of Darfur, of which he wished to make a new family: the Nyam-Nyam and Monbuttu were the chief. All are of a lighter color than the typical Negro, and their languages are more distinctive still. As above said, it is probable that many such groups can be segregated on the best of grounds.

Systems of Writing.— Africa has four living systems (not counting the fossil Coptic or the European used by those races), and has had four now represented only by inscriptions or papyri. The latter are: (1) Ancient Egyptian, passing from hieroglyphics (a mixture of ideograms and syllables) through the cursive hieratic to the more cursive demotic, the ordinary script of business life. A few of the demotic characters are preserved in the ritual Coptic. (2) Ancient Phœnician, the ancestor of all Western alphabets. (3) Ancient Ethiopian, used for the native tongue around Napata and Meroë. It was cursive and borrowed, but it is not known from whence, nor what language it represents. (4) Ancient Libyan or Numidian, borrowed from southern Arabia and read from the bottom up. There are many inscriptions in it in Algeria and Tunis, some of which have been deciphered; the first was the celebrated bilingual inscription of Takka. The living systems are practically those of the Hamites and Semites, the others being mostly below the grade of civilization which uses such things; and both the former use Semitic systems. The four are:

1. The only one developed in a Negro tribe, and with one exception the only one actually invented and popularly used within historic times: that of the Vei, on the west coast near Cape Mt., devised about 1834 by Doalu Bukere, a native

with a rough knowledge of European printing. It was not an alphabetic system, but a syllabary, with complicated characters like hieroglyphics. It was later used for Mohammedan missionary work, but is being supplanted by the European system, the Christian missionaries refusing to employ it.

2. That of the Touaregs or Saharan Berbers, called *tifinaghen*. It seems to be a descendant of the ancient Libyan, to which it is similar in reading from the bottom up.

3. The Arabic, used by all who wish to write the great language of Mohammedan Africa, the general medium of social and business communication. It is also widely used to write other African languages: by the Berbers and Suahelis for Libyan; by the people of Shoa for Amharic, and those of Harar for Harari; by the Malays of Madagascar; and by the Kaffirs.

4. The Amharic, used largely in and around Abyssinia; it is an extension and modification of the ancient Geez or Ethiopic, which therefore we have not classed as dead, any more than the Greek and Roman alphabets can be so called. It is written from left to right like the European languages, the other Semitic systems being the reverse; and the vowels are indicated by modifications of the consonants or marks added to them, making it a semi-syllabic rather than pure alphabetic system. It was borrowed from southern Arabia, and can be traced back to the 4th century on the monuments at Axum, the ancient capital of Abyssinia.

Political Divisions.— By recent arrangements, mainly since 1884, great areas in Africa have been allotted to Great Britain, France, Germany, Portugal, Belgium, and Italy, as coming within their respective spheres of influence, in addition to colonial possessions proper. The areas claimed by the various European powers in Africa may be roughly estimated as follows: France, 3,500,000 square miles; Great Britain, 2,600,000 square miles; Germany, 1,000,000 square miles; Portugal, 825,000 square miles; Kongo Free State, 900,000 square miles; Italy, 180,000 square miles; Spain, 154,000 square miles. See paragraph on *Colonies* under these various countries. Egypt, like Tripoli, is nominally under Turkey, but it is actually under British suzerainty. The Kongo Free State is under the king of Belgium. Abyssinia and Morocco are the chief native African and independent states. The former independent Boer republics, the Orange Free State and the South African Republic, since the Transvaal war 1899–1902, have been incorporated with the British empire under the name of the Orange River and Transvaal Colonies. In 1903 Great Britain also annexed Kano and Sokoto.

History of Discovery.— Although in Egypt and along the Mediterranean coast (see CARTHAGE and EGYPT) Africa was the seat of remote and comparatively high states of civilization, up to the middle of the 19th century the whole of central Africa was a blank; it is now at least as well known as South America. The civilized nations of the ancient world aproached Africa from the Mediterranean and the Red Sea; there is reason to believe that till the introduction of the camel in the 7th century A.D. the desert was an insuperable barrier between the Mediterranean countries and central Sudan.

The name Africa is mythologically associated with Afer, a son of the Libyan Hercules; but this is only an eponym. It is certainly Phœnician, and probably meant "nomadic," a term applied by the Carthaginians to the tribes around. It was the name given by the Romans at first only to a small district of Africa in the immediate neighborhood of Carthage, and nearly corresponding with the Roman province formed on the destruction of Carthage. The Greeks called Africa Libya, and the Romans often used the same name. The first African exploring expedition on record is that mentioned by Herodotus as having been sent by Pharaoh Necho about the end of the 7th century B.C. to circumnavigate the continent. The navigators, who were Phœnicians, were absent three years, and according to report they accomplished their object. The story has been the subject of much controversy, and was for long generally discredited, but recent authorities of weight have pronounced in its favor. The next important voyage recorded is that of Hanno, a Carthaginian, down the west coast, probably 50 or 100 years later. He passed a river with crocodiles and river-horses, and probably reached the coast of Upper Guinea. Herodotus also mentions some young men of the tribe of the Nasamones (living near the Gulf of Sidra) crossing the desert in a westerly direction, and coming to a great river where they saw crocodiles and black men, but it is doubtful if this could have been the Niger. There is no evidence that the Egyptians knew the Nile beyond the site of Khartum, though they may have sent ships as far as the coast of Somaliland by the Red Sea. Nero sent an expedition up the Nile which seems to have penetrated up the White Nile; and remains of Roman origin have been found some distance into the Sahara. From the navigators and traders that frequented the east coast of Africa, Ptolemy may have learned that the Nile issued from two great lakes about the equator. Mohammedanism was carried into north Africa in the 7th century and very rapidly spread to the Atlantic. By the 10th century the Arabs had crossed the desert, and between this and the 14th century Arab travelers visited central Sudan, the Niger, and other regions, and till comparatively recently they were the great authorities on much of central Africa.

The first impulse to a more complete exploration of Africa was given by the Portuguese prince known as Henry the Navigator, who in the early part of the 15th century sent out a series of expeditions along the west coast. These were continued after his death, so that in 1486 Bartolomeu Diaz doubled the Cape and in 1497 Vasco da Gama sailed up the east coast as far as Mombasa, and thence to India. Thus for the first time the main outline of the African coast was laid down. Settlements were planted on the east and west coasts by Portuguese, French, English, Dutch, and Brandenburgers, but there is no authentic information that any European penetrated into the interior. Maps of the 16th to the 18th century were covered with lakes and rivers, but these were swept away as unauthentic by D'Anville in the middle of the 18th century, and the interior left a blank. An association for the exploration of inner Africa was formed in London in 1788. Additions were made to geography under its auspices by Mungo Park, Hornemann, Burckhardt, and others.

10. Basketry.

Modern African exploration may be said to begin with Mungo Park, who reached the upper course of the Niger or Joliba, and whose efforts to explore the river to its mouth cost him his life (1795–1805). Dr. Lacerda, a Portuguese, about the same time reached the capital of Cazembe, west of Lake Bangweolo, where he died. Hornemann, who traveled for the same society as Park, perished in the desert after sending home accounts of Bornu and the neighboring states. In 1802–6 two Portuguese traders crossed the continent from Angola, through Cazembe's dominions, to the Portuguese possessions on the Zambezi.

In 1816 Captain Tuckey, in command of a British expedition, sailed up the Kongo, which he took to be the mouth of the Niger, for 280 miles. About the same time Major Peddie, and after his death Captain Campbell, led a party up the Senegal through the Fula or Fellatah territory, returning to Kakundy on the Nunez. In 1817 Mr. Bowditch explored the country of the Ashantis. In 1818 a French traveler, Gaspard Théodore Mollien, discovered the sources of the Senegal, Gambia, and Rio Grande. In 1819 Ritchie and Lyon traveled from Tripoli to Murzuk, and in 1821 Major Laing made some important journeys in the Mandingo district of western Africa. In 1822–4 extensive explorations were made in northern and western Africa by Major Denham, Capt. Clapperton, and Dr. Oudney, the last of whom died on the way. The travelers proceeded from Tripoli by Murzuk to Lake Tchad. While Denham examined the south and west coasts of the lake, Clapperton proceeded west through Bornu to Sokoto, the capital of the Fellahtah country, on the Sokoto, an affluent of the Niger. Impressed with the importance of establishing political and commercial intercourse with this district, Clapperton organized another expedition for the purpose of reaching Sokoto from the west coast. Setting out from Badagry, on the east of Cape Coast Castle, 7 Dec. 1825, and passing through the kingdom of Yoruba he reached the Niger at Bussa. Here he crossed the river and traversed the kingdom of Nupe to Kano, capital of the Haussa country, which he had previously visited, and from thence proceeded to Sokoto, in the neighborhood of which, after a short residence, he died. His servant, Richard Lander, returned to Kano and attempted to proceed south through the kingdom of Zegzeg, but was compelled by the natives to return to Darroro, from which he reached the coast.

W. Allen, a naval officer, about this time accompanied a mercantile expedition up the Niger, which he surveyed for a certain distance, and in another expedition in 1848 the same officer revised and corrected his survey. Maj. Laing in 1826 crossed the desert from Tripoli to Timbuctoo, but he was killed on his return, and his papers lost. René Caillié, after living for some years on the Senegal coast learning the language and initiating himself into the religion and manners of the Arabs, made in 1827–8 a journey to Timbuctoo, and thence through the great desert to Morocco. Richard Lander, accompanied by his brother, leaving Badagry for Bussa in March 1830, ascended the river Niger to Yauri, and descending from thence reached the mouth called the Nun in November. In 1832 he traced other mouths of the river up to the main stream; and the identity of the great river which passes under various names in different parts of its course was thus established.

In the south, Livingstone, who was stationed as a missionary at Kolobeng in 1849, passed through the desert of Kalahari, reached the Zuga or Botletle, and after a circuitous route discovered its source in Lake Ngami. In 1851 he went north again, proceeding from the Zuga in a more easterly direction. In lat. 17° 25′ S., and between lon. 24° 30′ and 26° 50′ E., he came upon numerous rivers flowing north, which were reported to be affluents of a larger river, the Zambezi.

In 1848 and 1849 Krapf and Rebmann, missionaries stationed near Mombasa, saw the Kilima-Njaro and the Kenia Mountains. In 1851 Francis Galton, starting from Walfisch Bay, made an extensive survey of the Damara and Ovampo countries, in which he found high pastoral and agricultural table-lands. An expedition under the patronage of the British government started from Tripoli in 1850 to visit the Sahara and the regions around Lake Tchad. Richardson, the originator of the expedition, was joined by two Germans, Drs. Overweg and Barth. In crossing the desert from Murzuk to Ghat they found some interesting sculptures. From Ghat to Aïr they found the country wholly desert and uninhabited. On reaching Lake Tchad Richardson went to Kuka, capital of Bornu, Barth to Kano, Overweg to the native states of Mariadi and Guber. Barth and Overweg met again at Kuka in April 1851, but in the meantime Richardson had died. Overweg explored the lake, and Barth proceeded on another journey south to Massena, in the kingdom of Bagirmi. On his return the death of Overweg left him to prosecute the enterprise alone. He proceeded to Timbuctoo via Kano, and after collecting much information about the Niger and its tributaries, over a great part of the course of which he traveled on his return to Kuka, he reached Tripoli in August 1855. Dr. Vogel, who was sent to join Barth, was put to death at Wadai, and his papers were lost.

Dr. Livingstone began another journey from Kolobeng on 15 Jan. 1853. After staying a month at Linyante, capital of the Makololo, he proceeded down the Chobe to Sesheke, and thence ascended the Leambye (Zambezi) to the junction of the Liba. After returning to Linyante, and taking with him a party of Makololo, he again set out 11 Nov. 1853, reached the Liba 27 December, and proceeded to Lake Dilolo, where he found the watershed of the streams which flow north and south (feeders of the Kongo or the Zambezi) at a level of 4,000 feet above the sea. On his return journey he was confirmed in the belief that an elevated plateau here crosses the country and forms the watershed of the whole continent. He next crossed the Cassabi river, and on 4 April he reached the banks of the Kwango, both these rivers being affluents of the Kongo. Crossing the Kwanza, he reached Loanda on 31 May. On 20 September he set out on his return journey, and following pretty nearly the route by which he had gone arrived at Linyante. Starting from this place on 3 Nov. 1855, he reached the Zambezi, and proceeding down the river, and visiting its falls, called by him the Victoria Falls, arrived at

Kilimane at its mouth on 20 May 1856, and sailed for England. Thus was accomplished by Dr. Livingstone the remarkable feat of crossing the entire continent from sea to sea — the first time, so far as is known, that this was done by any European. In 1858 Livingstone returned to resume his exploration of the Zambezi regions. Entering the Congone mouth of the river in May, he ascended its tributary, the Shire, to Murchison Cataracts, visited Lake Shirwa and Lake Nyassa, traveled on or near the Zambezi to Victoria Falls, established the identity of the Leambye and the Zambezi, sailed up the Shire to Lake Nyassa, also sailed 156 miles up the Rovuma River, and returned to England in 1864.

Between 1856 and 1865 Paul du Chaillu traveled extensively on the west coast, in the neighborhood of the river Ogowe (or Ogobai). In 1861–2 Major (afterward Sir) R. F. Burton also traveled on the west coast. He ascended the Kamerun Mountains and confirmed some of the observations of Du Chaillu. A French expedition visited the delta of the Ogowe in 1864. Since then that river has been very fully explored, the principal expeditions having been those of Walker, 1866, 1873; Lieut. Aymes, 1867–8; the Frenchmen Compiègne and Marche, 1872–4; Dr. O. Lenz, 1876; and another French expedition under Savorgnan de Brazza, 1876, who took possession of a large stretch of territory for France. This territory now forms part of French Kongo, which had been traversed by various Frenchmen, including Brazza, Mizon, Le Maistre, Monteil, and others.

In 1866 Livingstone entered on his last great series of explorations, the main object of which was to settle the position of the watersheds in the interior of the continent south of the equator, and to discover the source of the Nile. Landing at the mouth of the Rovuma he proceeded southwest round the south end of Lake Nyassa, and then traveling north reached the south end of Lake Tanganyika (discovered by Speke and Burton in 1858). He afterward visited Lakes Mweru and Bangweolo in the basin of the Chambeze, the name given to a headwater of the Kongo. In 1869 he reached Ujiji, on the Tanganyika, and crossed the lake, making extensive journeys in the Manyuema country, and reached the Lualaba or upper Kongo, but could not explore it for want of boats. Henry M. Stanley, who had been specially sent by the proprietor of the New York *Herald* to search for Livingstone, met him at Ujiji on his return from the Manyuema country, relieved his necessities, and examined along with him the northern end of Lake Tanganyika. Livingstone afterward started on a fresh journey (in 1872) to determine the course of the Lualaba, intending to travel round the south side of Lake Bangweolo; but after suffering much from illness he died on the shore of this lake on 1 May 1873.

In 1872 the Royal Geographical Society organized two expeditions to go in search of Livingstone. The one, under Lieut. Grandy, sailed some distance up the Kongo; the other, under Lieut. Cameron, started from Zanzibar for Tanganyika. On ascertaining the death of Livingstone he proceeded to Lake Tanganyika, where he secured Livingstone's map and sent it to Zanzibar. He ascertained the height of the lake; found an outlet, the Lukuga, on the west side; traversed the Manyuema country; reached Nyangwe, Livingstone's farthest point on the Lualaba; proceeded south up the east side of the valley of Lomane to Kilemba in the Urua country; and reached Benguela, on the Atlantic coast, 4 Nov. 1875. The identity of the Kongo and Lualaba was at last settled by Stanley, who, between October 1876 and August 1877, descended from Nyangwe on the latter river to the mouth of the former. After helping to establish the Kongo Free State (1879–85) Stanley proceeded in 1887 with an expedition to relieve Emin Pasha, governor of Egypt's equatorial province. Following the Kongo and its tributary the Aruwimi, Stanley hewed his way through a vast forest, arrived at the Albert Nyanza, met Emin there, returned for his rear-guard and stores, and at last brought Emin and his followers to Bagamoyo, on the east coast, in 1889. He also discovered Lake Albert Edward and the lofty mountain of Ruwenzori, on the Semliki, between that lake and Lake Albert. The Portuguese Maj. Serpa Pinto journeyed from Benguela to Natal in 1878–9; the Germans Wissmann and Pogge crossed from St. Paul de Loanda to Zanzibar in 1881–2; in 1879–80 (after the death of his leader, Keith Johnston), Joseph Thomson crossed from the east coast by the north of Lake Nyassa to the east of Tanganyika, and back to Zanzibar; again in 1883–4 he explored the Masai country between the coast and Lake Victoria; Capello and Ivens went from Angola to Mozambique by way of Bangweolo in 1884–5.

One of the most interesting problems connected with African geography was the tracing of the source of the Nile. Among the first of the famous explorers in this direction was James Bruce, who in 1770 reached the source of the Blue Nile or Bahr-el-Azrek, and imagined himself to have solved the great problem. But the real source of the Nile remained long unknown, the great lakes connected with its origin being hardly dreamed of till comparatively recent times. In 1858 Burton and Speke, crossing from Zanzibar, discovered Lake Tanganyika, and the same year Speke also reached the Victoria Nyanza, but did not ascertain that it gave rise to the Nile. Speke and Grant in 1862 reached the place where the Nile leaves the lake and followed part of its course to Karuma Falls. At Gondokoro they met Sir Samuel Baker, who proceeded to investigate the unexplored part, but did not fully succeed in his object. Baker in 1871–3 returned to the scene of his explorations as the commander of an Egyptian force, and took possession of the country in the name of the Khedive, but added little to his previous geographical discoveries. He was succeeded in his command by Col. Gordon, one of whose officers, Col. Long, more fully traced the Nile between Karuma Falls and the Victoria Lake; while another, M. Gessi, first actually traced the Nile up to its outflow from the Albert Nyanza (1876).

Since 1883 the exploration of Africa has been carried out by a multitude of explorers. In the north the French have pushed south from Algeria, and French explorers, among whom M. Foureau is prominent, have added greatly to our knowledge of the Sahara. Dr. Junker devoted several years to exploring the country between the basin of the Nile and the Kongo. Mr.

Stanley in his great journey across Africa in 1876 added largely to our knowledge of Lake Victoria, and of Uganda, the country between Victoria and Lake Albert. Since the British occupation of Uganda, Col. Lugard and many other officers have mapped the country between the coast and the lakes, Uganda itself, and the country to the west. Italian and British explorers have added to our knowledge of Abyssinia and of the desert between the Nile and the Red Sea. Lakes Rudolf and Stefanie have been discovered and explored by Count Teleki and Lieut. Von Höhnel from the south, while James, Donaldson Smith, Cavendish, Robecchi, Bottego, and others have explored Somaliland and ascertained that the Omo flows into Lake Rudolf. Gregory has investigated Mount Kenia; Meyer has ascended Kilima-Njaro; Baumann and other German explorers have visited the region to the west and south of that mountain, round by the south of Lake Victoria, and on to Lake Albert Edward. In 1894 Count Götzen crossed from east to west, discovered Lake Kivu to the south of Lake Albert Edward, and a lofty active volcano near its shores, coming out by the Kongo. Many other Germans have been busy in German East Africa, while in British Central Africa, Johnston, Sharpe, Joseph Thomson, and others have filled in many blanks, and British naval officers have charted Lake Nyassa.

The unique distinction of being the first white man to traverse Africa from south to north on foot fell to the lot of an undergraduate of Cambridge University, Ewart Scott Grogan, who in February, 1898, started from Cape Town with one white companion and a few servants, and eighteen months later reached Cairo, having traveled the greater part of the distance with only the servants, as his white friend left him before the journey was half done. Mr. Grogan brought back a mass of ethnological information, having carefully investigated and described the various tribes with which he came in contact, and cleared up a number of disputed geographical points. See 'From Cape to Cairo.' London, 1900.

Several German explorers have also traversed and mapped Damaraland and Namaqualand; Lugard has explored the Uganda region: Gibbons and others have traversed the Barotse country. The officials of the Kongo Free State have laid open the courses of the numerous rivers that feed the main stream; Hinde found the Lukuga flowing into the Lualaba; Grenfell and others established the connection of the Ubangi or Mobangi tributary on the north, with the Makua-Wellé higher up, which had been explored by Junker and others. Under the auspices of the Royal Niger Company Joseph Thomson and others further explored the Niger; while the Benue and its tributaries and the German sphere in the south have been actively explored by British, French, and German travelers.

All these three nationalities, moreover, have been busy in the vast area between the Guinea coast and the great bend of the Niger. Prominent among them was Binger, who contributed more than any single individual to our knowledge of this region. The French occupation of Timbuctoo has led to the navigation and exploration of the upper and middle river by gunboats; while a French expedition followed the river from Timbuctoo to its mouth. Monteil crossed from Senegal to Lake Tchad and traversed the desert to Tripoli. French expeditions have crossed from the Kongo to the Nile, and all the river systems are now mapped in their main features. It may indeed be said that the pioneer exploration of Africa has been completed, the most important blank being the region lying between Somaliland and the upper Nile. What remains to be done is the filling up of the meshes between the vast network of explorers' routes, and this is a task which cannot be completed for many years.

Commercial Conditions.—Necessarily in so large an area with so many tribes and peoples who keep no accounts of their transactions, a considerable amount of commerce must pass without being recorded in any way, yet the annual commerce of Africa, of which statistics are available, amounts to over $700,000,000. The total imports at the ports where records are kept amounted in the latest year for which figures are at hand to $429,461,000, and the exports to $263,907,000. The principal imports were distributed as follows: Into British territory, $157,575,000; French territory, $92,004,000; Turkish territory, $77,787,000; Portuguese territory, $20,795,000; German territory, $8,336,000, and into the Kongo Free State, $4,722,000. Of the exports a large share, especially those from the south, is gold and diamonds; in the tropical region ivory, rubber, palm nuts, and gums, and in the north a fair share of the exports are products of agriculture, cotton, coffee, cacao, spices, dates, etc. The export figures of recent years are less than those of former years, owing to the hostilities in South Africa, which have both reduced production and increased local consumption.

Railroad development in Africa has been rapid in the past few years and seems but the beginning of a great system which must contribute to the rapid development, civilization, and enlightenment of the « Dark Continent.» Already railroads run north from Cape Colony about 1,500 miles, and south from Cairo about 1,200 miles, thus completing 2,700 miles of the proposed « Cape to Cairo » railroad, while the intermediate distance is about 3,000 miles. At the north numerous lines skirt the Mediterranean coast, especially in the French territory of Algeria and in Tunis, aggregating about 2,500 miles; while the Egyptian railroads are, including those under construction, about 1,500 miles in length. Those of Cape Colony are over 3,000 miles in length, and those of Portuguese East Africa and the Transvaal are another 1,000 miles in length.

Including all of the railroads now constructed or under actual construction, the total length of African railways is nearly 12,500 miles, or half the distance around the earth. In 1903 the construction of a railroad from Khartum to Suakin was begun. A large proportion of the railways thus far constructed are owned by the several colonies or states which they traverse, about 2,000 miles of the Cape Colony system and nearly all of that of Egypt belonging to the state.

That the gold and diamond mines of South Africa have been and are still wonderfully

profitable is beyond question. The Kimberley diamond mines, about 600 miles from Cape Town, now supply 98 per cent of the diamonds of commerce, though their existence was unknown prior to 1867, and the mines have thus been in operation but about 30 years. It is estimated that $350,000,000 worth of rough diamonds, worth double that sum after cutting, have been produced from the Kimberley mines since their opening in 1868-9, and this enormous production would have been greatly increased but for the fact that the owners of the various mines there formed an agreement to limit the output so as not to materially exceed the world's annual consumption.

Equally wonderful and promising are the great Witwatersrand gold fields of South Africa, better known as the Johannesburg mines. Gold was discovered there in 1883, and in 1884 the value of the gold product was about $50,000. It increased with startling rapidity, the product of 1888 being about $5,000,000; that of 1890, $10,000,000; 1892, over $20,000,000; 1895, over $40,000,000; and 1897 and 1898, about $55,000,000. Work in these mines was practically suspended during the Boer war.

The gold production of the «Rand» since 1884 has been over $300,000,000, and careful surveys of the field by experts show beyond question that the «gold in sight» probably amounts to $3,500,000,000, while the large number of mines in adjacent territory, particularly those of Rhodesia, whose output was valued at over $4,500,000 in 1901, gives promise of additional supplies, so that it seems probable that South Africa will for many years continue to be as it is now, the largest gold-producing field of the world.

African International Association, an association formed in 1876 at Brussels for the purpose of establishing scientific stations in east Africa; the outcome of King Leopold's first Brussels conference of explorers and geographers to devise means for opening up Africa to civilization. At a second one the next year, after Stanley's discoveries of the immensity and prospective commercial importance of the Kongo basin, the Association planned to extend its operations there. But the territory was too vast and rich for any great nation to forego its share or let others lock up; finally all (the United States being a party) agreed to leave it to an international conference at Berlin. This opened 17 Nov. 1884 (Prince Bismarck chairman) and closed 26 Feb. 1885. The result was the creation of the Kongo Free State (q.v.), comprising the basins of the Kongo and its affluents, with the king of Belgium as sovereign: to be forever neutral, with perfectly free trade and transportation for citizens of any country whatever, no monopolies or concessions of any kind for its trade to be granted by powers adjoining, all of whom bound themselves to suppress slavery.

African Slave Trade, see Negro, The.

African War, The, in Roman history, Cæsar's campaign against the Pompeians who after Pharsalia kept up the war in Africa, and were crushed at Thapsus, 46 B.C. The history of it printed as Cæsar's is not his, and the author is unknown.

Afridis, af-rē'dēz, a tribe of Afghans or Pathans on the northwest Indian border near the Khyber Pass, who after many years of the customary border raids were dignified into almost a great power by the ill-advised policy of the Indian government in sending out an imposing army against them in place of the usual small punitive expeditions. The tribe sent their women into the English camp to be cared for and protected, fought for some months in their mountains till the planting season was come, then submitted and promised an indemnity, having enjoyed the highest glory and felicity their natures could appreciate. Holdich (‹Anthropological Institute› for 1899) thinks they represent the early Aryan type, wild but shrewd and civilizable.

Afrikander («Taal» Dutch for African), a native South African; commonly used for the Dutch stock alone.

Afrikander Bond or **Bund,** an association of white natives of South Africa to make native influence paramount there and ultimately secure its independence; formed in 1879, but thus named in 1880. The Cape Colony wing supported Cecil Rhodes till after the Jameson Raid in 1895, which it considered as fostered by him with objects exactly contrary to its own. It carried the elections in 1898, and while advising Kruger to grant concessions to the Outlanders for safety's sake, its sympathies were hostile to them; in the ensuing war it was a heavy handicap to the English, seeming likely at one time to add Cape Colony to the revolt; indeed, it held a convention, 6 Dec. 1900, at Worcester, C. C., condemning the war and English policy, insisting on the recognition of the South African Republic, and censuring the policy of the High Commissioner. The success of the British and the annexation of the territory to the empire of Great Britain brought about a dissolution of the organization.

After-damp, the gaseous product formed by an explosion of fire-damp (q.v.) in a coal mine. It consists largely of nitrogen from the

air, and carbon dioxide formed by the explosive combustion of the hydrocarbon gas given off by the coal. It seldom contains sufficient free oxygen to support respiration. Hence its danger to the miners.

Afterglow, a display of brilliant colors in the western sky after sunset. The colors are usually various shades of red, although yellows and grays are sometimes visible. Afterglows follow volcanic eruptions of explosive character and are generally ascribed to the presence of minute dust particles in the air. The eruption of Krakatoa in 1883 was accompanied by most gorgeous afterglows which were observed throughout the world and persisted for several years. Similar effects were seen over a much smaller area after the outbursts of Mont Pelée and La Soufrière in May 1902. The name foreglow is given to such displays in the eastern sky before sunrise.

After-image, After-sensation, and **After-percept** are the terms used to denote the direct after-effects of the stimulation of a sense organ. These after-effects occur in almost all of the sense departments. A brief stimulation of the sense organ gives a primary sensation, then a pause of a fraction of a second, followed by a secondary sensation of the same quality as the primary sensation. After-images of touch follow after brief contact. They do not appear under ordinary circumstances, but may be observed if special conditions are produced; for example, a gentle tap of a point of a needle will be followed by a pause, then an after-sensation which differs from the primary sensation in that it seems to be produced from within the body, not from without. The effects of a temperature stimulus may persist for a time in the same quality as the primary sensation. After-taste and after-smell have been observed, but have not been studied. Auditory after-sensations, analogous to after-sensations of touch, are very weak and of brief duration.

After-images of vision are stronger and more permanent, consequently have been given much more attention by experimentalists. It has been found that after the retina has been stimulated by light for one second, or less, the primary image disappears quickly; an interval of less than two seconds is then followed by a positive after-image, that is, an after-image of the same quality as the primary image.

A stimulus of longer duration is followed immediately by the positive after-image, and this image may itself be followed by a negative after-image, that is, an image which differs very much in brightness from the primary image, or is of a different color. With some observers a brief stimulus is followed immediately by a negative after-image, which fades away quickly to be followed after an interval by a more permanent positive after-image. Several images may succeed each other immediately or be separated by an interval of time. A stimulus of still greater duration is followed directly by a negative after-image. In such cases the after-image is usually of a color that is complementary to the color of the primary image, especially if observed with closed eyes or if projected upon — that is, seen while looking at — a gray background. The duration of the after-image varies with the intensity, duration, and area of the stimulus. The results of experiments, under conditions such that the intensity of the light does not vary, have not as yet shown that any one color has more power to produce after-images than any other color. The greater the angular distance of the portion of the retina stimulated, from the fovea, the less distinct and the less durable is the after-image. There seems to be no after-image at an angular distance of 45° or more from the fovea. The explanation for this fact may be physiological, or psychological, or both; that is, it may be due to the fact that the periphery of the retina is more easily fatigued than the fovea, or it may be due to lack of ability to attend to those portions of the retina which are not customarily attended to. When an object occupies the attention, the eye is so directed toward it that the image falls over the fovea; the mind does not ordinarily attend to images that are not over or very near the fovea.

A blow on the head may cause the after-image to become less intense or to cease entirely. Electrical stimulation of the eye and optic nerve will change the character of the after-image and shorten the time of its duration. General fatigue will shorten the duration of the after-image; for example, it has been found that an after-image lasts about 30 per cent longer in the morning than in the evening. The distraction of attention in any manner has its effect on the course of the after-image; when the attention is directed wholly upon the after-image the duration is one third longer than when the attention is not concentrated upon it.

If one eye only be stimulated, an after-image may appear in the unstimulated eye. Four hypotheses have been offered to explain this transfer of the image from one eye to the other: (1) The appearance is a phenomenon of binocular contrast. When one eye is stimulated by a bright colored light, and the other eye is stimulated by a very little gray light or is protected from all light, the contrasted color may be seen in the unstimulated eye during the time of stimulation, and this may leave an after-image in that eye. (2) A second hypothesis is that the eyes are accustomed to function together, and whatever affects one retina affects the other also. This may be considered as a modified form of the first hypothesis. (3) Another hypothesis is that the after-image has its seat in the centres in the brain, not in the end organ or retina, and that it may be seen in whichever eye is open. This hypothesis seems to be overthrown by the fact that an electrical stimulation of the optic nerve produces a sensation like that produced by a flash of light, but no after-image follows. Another fact difficult for this hypothesis to explain is that if one eye be stimulated the after-image appears in the other eye only in case that eye be well darkened. (4) A fourth hypothesis is that the transfer of the after-image is not real but only apparent. In support of this hypothesis it has been found that when «that portion of the right eye which corresponds to the blind spot of the left eye was stimulated,» (Franz) there was an apparent transfer of the image to the left eye; also if the unstimulated eye be disturbed or interfered with during the course of the after-image no change in the image may be observed, whereas if the stimulated eye be interfered with the image disappears.

(Fechner, ‹Elemente der Psycho-physik›; S. I. Franz, ‹After-Images,› Psych. Rev., Monograph Supplement, Vol. III., No. 2, 1899; E. B. Titchener, ‹Ueber binocular Wirkungen monocular Reize.› See EYE; VISION.

Afzelius, Arvid August, äf-tsā'li-oos, ar'-vēd ow-goost', Swedish scholar and author: b. 1785; d. 1871; pastor at Enköping 1821–71; specially esteemed for his researches in Old Norse history and literature. He wrote poetical ‹Romances›; translated the Elder Edda, and with Geijer edited a famous collection of Swedish folk-songs (3 vols. 1814–17).

Ag, the chemical symbol for the element silver. It is an abbreviation of *argentum*, the Latin name for silver.

Agades, ä'ga-dez, a town of Africa, near the middle of the Sahara, capital of the oasis kingdom of Aïr or Asben; at one time a seat of great traffic, probably containing 60,000 inhabitants. In 1903 it had a population of about 6,000.

Agag, ā-gag, (1) in Jewish history, a king of the Amalekites saved by Saul out of the slaughter of his people, and hewn in pieces by Samuel before Yahwe's altar: evidently a survival of human sacrifice. (2) A character in Dryden's ‹Absalom and Achitophel,› representing Sir Edmund Berry Godfrey, the London magistrate found murdered shortly after taking Titus Oates' deposition concerning the imaginary «Popish Plot.»

A'gai, Adolf, ä-goy, a Hungarian humorist: b. 1836. He edited the chief Hungarian comic paper, *Borzsem Janko* (John Peppercorn), and wrote for it brilliant sketches of society, character drawings of national types, etc., of a high order of wit and humor.

Agalmatolite, ag-al-mat'ō-līt (from the Greek words *agalma*, image, and *lithos*, stone), a soft, massive stone, grayish or greenish in general hue, and often yellow, brown, and red, or streaked with those colors. It is soft enough to be cut with a knife, and it takes a good polish. The Chinese use it for carving images, notably small pagodas and grotesque figures of animals and men; ingenious advantage often being taken of its varied colors for the production of odd effects. The hardness of the Chinese variety is mostly from 2.0 to 2.5, and its specific gravity about 2.8. It is not a definite mineral, some specimens being silicious pinite, while others are referable to pyrophyllite and steatite.

Agama (Caribbean name), a genus of lizards, typical of the large and important family *Agamidæ*, which is distributed over all Africa (except Madagascar), Arabia, Asia south of the Caucasus and Himalayan mountains, the Malayan Islands, and Australia. None are found in the New World. They are closely related to the iguanas, and are characterized by acrodont dentition (that is, the teeth surmount ridges of the jaw), a broad and short tongue, and the absence of bony tubercles (*osteoderms*) in the skin, but large and numerous spines are often present. They may have brilliant colors, but many are dull, desert-inhabiting species. Some have parachutes, as the flying dragon, and others defensive appendages, as the frilled lizard. Prominent examples are the dragons, bloodsuckers, false chameleons, frilled lizards, spiny-tailed desert lizards, dabs, molochs, and related forms elsewhere described under their own names. The family contains about 200 species arranged in about 30 genera, and is most numerous in the region from India to Australia.

Agamemnon, in the Iliad, is the Greek «great king» or «king of kings,» the overlord of Greece both north and south of the Gulf of Corinth; the royal seat is at Mycenæ in the Peloponnesus. He is represented as a rather weak man, presiding over a turbulent assembly of practically independent feudal chiefs, who will not openly defy him because he is consecrated to his position by Zeus, but who are entirely independent as regards their individual districts, though bound to follow him to war when ordered. His character is of course purely the invention of the poet, and its relation to that of Achilles and other chiefs is curiously like that of Charlemagne to Roland and the peers in the *chansons;* the dashing noble being the real hero, and the monarch slurred as rather petty, unjust, and capricious, king by grace rather than special merit. But the position is not fictitious: archæology has proved that Mycenæ was really the seat of a wealthy and powerful monarchy, probably about 1500 B.C. and somewhat after, as well as that several Troys flourished and perished; and these proofs that the basis of the story was traditional and not mythical naturally tempt the sanguine to hope for further points of truth, which research tends steadily to justify. As to the character of the monarchy, later theorists take the reverse view from the earlier. Grote held that the account in Homer showed the germ of a developing constitutionalism, the criticising commons who were becoming a thorn in the monarch's flesh being satirized and caricatured in Thersites, and the king only an Aryan chief elected by his equals; Mahaffy thinks it the decay of a monarchy of the Oriental type, the feudal anarchy indicating break-down instead of growth. In the legend he is the son of Atreus (q.v.), and brother of Menelaus, king of Sparta, whose wrong in the seduction and carrying away of his wife Helen (q.v.) by Paris, son of Priam, king of Troy, he avenges by a levy of all the Greeks to make war on Troy, when its king Priam will not give up Paris or make him give up Helen. (See HELEN; ILIAD; TROY.) The sacrifice of his daughter Iphigenia (q.v.), to secure a passage from Aulis, is a later fiction, and recalls Jephthah and his daughter curiously. His quarrel with Achilles is the theme of the Iliad. When Troy was sacked, he received Priam's prophetess-daughter Cassandra (q.v.) among his share of the spoils. Returning home after 10 years' absence, he was murdered by his cousin Ægisthus, son of Thyestes (see ATREUS), aided by Agamemnon's wife Clytemnestra (q.v.) with whom he had been living in adultery for a short time previously; and his son Orestes on growing up avenges him by killing his mother, his sister Electra abetting. In Homer, the motive for Agamemnon's murder is simply that of any adulterous pair in ridding themselves of an inconvenient husband; in Æschylus' ‹Agamemnon,› Clytemnestra slays him with her own hand, professedly in revenge for his sacrifice of Iphigenia, obviously sharpened by jealousy of Cassandra, and throwing the ultimate responsibility on Nemesis, who is pursuing the house of Atreus.

LIZARD (*Agama colonorum*). BEETLE (*Ateuchus sacer*). HORNED VIPER (*Cerastes cornusus*).

Agamenticus, Mount, a noted landmark in York co., Maine, near which one of the earliest settlements in this territory was made in 1631. It is a few miles back from the shore and rises to the height of 673 feet.

Agamogenesis. See PARTHENOGENESIS.

Agaña, äg-än'ya, the principal town of Guam, the largest of the Ladrone Islands, 1,500 m. E. of Luzon, Philippines, and 1,300 m. S. of Yokohama. The Ladrone, or Marianne, group belonged to Spain; but, as a result of the war between the United States and Spain in 1898, the former took possession of the island of Guam, and in 1899 established a naval station and seat of administration at Agana, with Capt. Richard P. Leary, U. S. N., as first governor. The town contains the usual public buildings of a military station, and a college.

Aganippe, -nip'ē, a fountain on Mount Helicon, in Greece, sacred to the Muses, which had the property of inspiring with poetic fire whoever drank of it.

Agape, ag'a-pē (Gr. *agapē*, love), in ecclesiastical history, the love-feast or feast of charity, in use among the primitive Christians, when a liberal contribution was made by the rich to feed the poor. During the first three centuries love-feasts were held in the churches without scandal, but in after-times the heathen began to tax them with impurity, and they were condemned at the Council of Carthage in 397. Some modern sects, as the Wesleyans, Sandemanians, Moravians, etc., have attempted to revive this feast.

Agapemone, ag-a-pem'o-nē (lit. « the abode of love »), the name of a singular conventual establishment which has existed at Spaxton, near Bridgewater, Somersetshire, since 1859, the originator of it being a certain Henry James Prince, at one time a clergyman of the Church of England, who called himself the Witness of the First Resurrection. The life spent by the inmates appears to be a sort of religious epicureanism. Some of the proceedings of the inmates of the « Abode of Love » have resulted in applications to the courts of law, where parties formerly members of the society have returned to the world and sought to regain their rights from Prince and his followers, and such cases have caused some scandal; but the sect has been scarcely heard of for some years.

Ag'aphite, a name given to the turquois (q.v.) by Fischer, in 1806, in compliment to the naturalist Agaphi. It is no longer in general use.

Agar-agar, ä'gär-ä'gär, also known as Bengal isinglass. A dried seaweed or vegetable gum obtained from Singapore. It is almost completely soluble in water, dissolving to a tasteless and odorless mass. It is much used as a culture medium in bacteriology.

Agar'ic (*Agaricus*), a genus of fungi, characterized by having a fleshy cap or pileus and a number of radiating plates or gills on which are produced the naked spores. The majority of this species are furnished with stems, but some are attached to the objects on which they grow by their pileus. Over a thousand species are known, and are arranged in five sections according as the color of their spores is white, pink, brown, purple, or black. Many of the species are edible, like the common mushroom (*A. campestris*), and supply a delicious article of food, while others are deleterious and even poisonous. See FUNGI; MUSHROOMS.

Agaricic Acid, ag-ar-is'ik, a substance having the formula $C_{16}H_{30}O_5$, which is obtained from certain species of mushrooms by extraction with ether or strong alcohol. It is also soluble in hot glacial acetic acid and oil of turpentine. It crystallizes in flat, four-sided plates, and also in prisms, according to the solvent from which it is deposited, and melts at about 290° F. It dissolves in boiling water, but crystallizes out again upon cooling. A similar substance, known as agaricin, is obtained from the fly-agaric by extraction with alcohol, and Jahns states that it is identical with agaricic acid. Several salts of agaricic acid are known. See AGARIC RESIN.

Agaric Mineral, ag'a-rik, or a-gar'ik. (1) A soft, white variety of calcite, breaking easily in the fingers, and occurring in caverns and in the clefts of rocks, in regions where the ground water contains much lime. (2) A variety of silicate of magnesium, found in Tuscany, and also known as mountain-milk or rock-milk. Bricks made from it will float in water; hence it is supposed that this is the material from which the ancients made their floating bricks.

Agaric Resin, a red resinous substance, obtained from certain mushrooms, together with agaricic acid (q.v.) by extraction with alcohol or ether. It melts at 194° F. It is insoluble in water, but dissolves in absolute alcohol, ether, wood alcohol, chloroform, and alkalies.

Agassiz, Alexander, ăg'ăs-sĭ (1835), son of Louis: b. Neuchatel, Switzerland, but taken to America in 1848 and educated at Harvard College, from which he was graduated in 1855. In 1859–60 he made biological studies along the coast of California and Mexico with the United States coast survey. Later he became wealthy through investment in coal and copper mines, to which he was led by scientific knowledge and experience. On his father's death he was appointed curator of the Museum of Comparative Zoology at Harvard, but resigned in 1885 on account of ill health. In 1896 he was made an officer of the Legion of Honor. He belongs to many scientific associations, has done much important work in marine dredging and the zoology of the deep sea, as well as on other subjects. His most important publications are ‹North American Acalephæ› (1865); ‹Marine Animals of Massachusetts Bay› (with Elizabeth Agassiz, 1871); ‹Revision of the Echini› (1872); ‹North American Starfishes› (1877); and ‹Report on the Echini of the Challenger Expedition› (1881).

Agassiz, Louis (1807–73), a naturalist: b. 28 May at Motier, Canton Fribourg, Switzerland, but during the latter part of his life identified with the advancement of science in the United States. From childhood he showed a strong bent toward zoology, and, after a preparatory training at Lausanne, studied medicine and natural history at Zurich, Heidelberg, and Munich, taking a degree in philosophy at Heidelberg and graduating in medicine at Munich, 1830. After this he went to Paris and worked under Cuvier until 1832, when he was called to Neuchatel as professor of natural history, and remained there until 1846, when invited to give a series of lectures in the Lowell Institute course at Boston. The success of these lectures and

his desire to study the natural history and geology of America determined his permanent removal to the United States; in 1848 he was given the chair of natural history in the Lawrence Scientific School of Harvard University. With the interval of three years (1851–54) as professor in the medical college at Charleston, S. C., he continued his connection with Harvard until his death. His enthusiasm, eloquence, and clearness of thought made him a pre-eminent teacher, but in his later years he was relieved from the regular duties of the school.

His first great work, ‹Recherches sur les Poissons Fossiles› (5 vols., 311 plates, 1833–42), was accomplished during his professorship at Neuchatel. This was followed by ‹Fossil Fishes of the Old Red Sandstone of the British Isles,› written after making several visits to England, and by the ‹Nomenclatoris Zoölogicus Index› (Soliduri, 1842–46), which, revised and brought up to date by Scudder, was re-issued in 1882 as Bulletin No. 19 of the U. S. National Museum. During this same period he had studied both living and fossil echinoderms, and had spent many summers in observing glacial action. The most eminent European biologists, botanists, and geologists were among his friends, and he came to America with the hope not only of advancing science by his own researches, but of waking a deeper interest than American students had yet shown in the natural sciences. His first wife had died in Europe; he remarried in America, and became so engrossed with the work he had undertaken as to refuse the most flattering offers of positions in Europe. In constant demand, and traveling widely as a lecturer as long as his health permitted, he was nevertheless constantly forwarding his original work. In 1848 he made a geological and biological survey of the northern and eastern shores of Lake Superior; in 1850–51 he studied the coral reefs of Florida; later he visited Brazil and the coasts of California.

His zeal was untiring, even after his health failed; besides working through all his later life on his great series, ‹Contributions to the Natural History of the United States,› which he had planned on so large a scale that the four quarto volumes completed were but a beginning, he directed constant efforts toward the establishment of the Museum of Comparative Zoölogy at Harvard, giving more attention to it than to any other of his later interests. The plans for it were perfected in 1858, and through his influence the original endowment was supplemented by generous appropriations; he gave his own valuable collections to it, and his time and money as well; before his death the opportunities which he had created there had attracted a group of young men who were to become the foremost American biologists. The founding of a summer school where zoölogy could be studied out of doors was another of his projects, and this he accomplished on the island of Penikese, Buzzard's Bay, in 1873, just before his death.

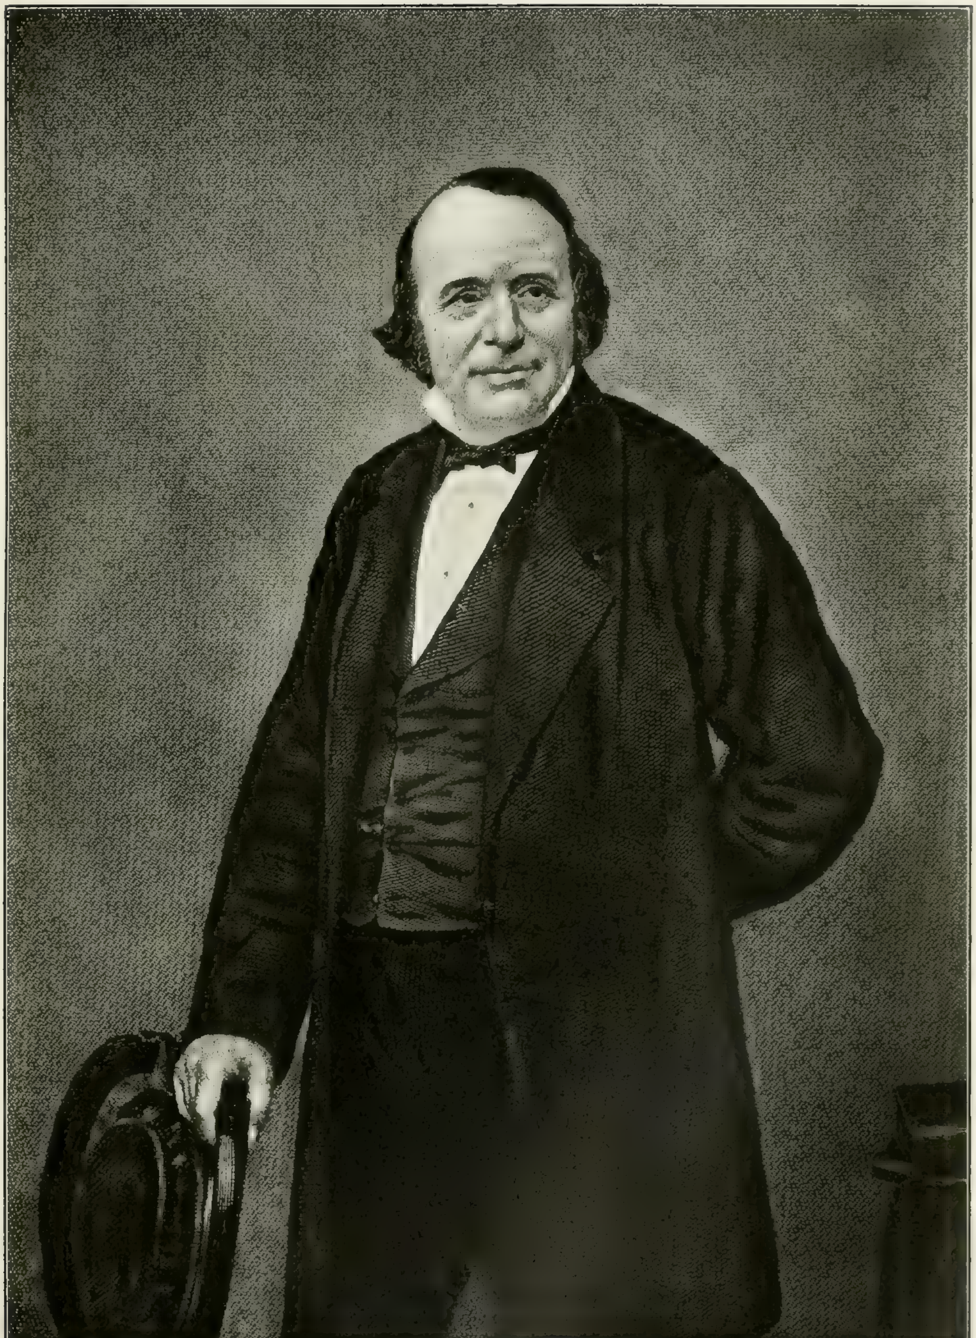
Among his more important American publications are ‹Methods of Study in Natural History›; ‹Geological Sketches›; ‹The Structure of Animal Life›; ‹A Journey to Brazil›; and ‹An Essay in Classification› (the first volume of his unfinished ‹Contributions›). The amount and scope of his work, together with his great gift of awakening interest in the natural sciences and advancing new views without rousing the opposition of the dogmatic, gave him rank as the most influential of American naturalists, although many of his opinions and theories have been superseded by the Darwinian idea of evolution, which he opposed. He died 14 Dec. 1873, and was buried in Mount Auburn Cemetery, where his monument is a boulder from the Aar glacier in Switzerland. (‹Life and Correspondence of Agassiz,› Boston, 1886.)

Agassiz, Mount, a remarkable extinct volcano situated in Arizona about 70 m. northeast of Prescott. It has an altitude of more than 10,000 feet above the sea, and belongs to the ranges of the Rocky Mountains. As a place of resort it has numerous attractions,— grand scenery, elevation, and proximity to the Colorado Cañon.

Agassiz Association, an organization for the promotion of nature study among youth. The society was established in 1875, and in 1902 had a membership of more than 12,000. The headquarters are at Pittsfield, Mass. The official publication is ‹The American Boy,› and the badge is a Swiss cross.

Agate, a variety of chalcedony, or cryptocrystalline quartz, distinguished by its banded or clouded appearance or by the presence of visible impurities. "Achates" was the Greek name of a river in Sicily near which, according to Pliny, agates were first found; but the name was earlier used by Theophrastus in his treatise ‹On Stones,› published about 315 B. C., while agate is mentioned in Exodus xxviii. 17 as one of the precious stones in the breastplate of the high priest. Its history, therefore, extends over a period of at least 3,400 years.

The method of formation of banded agates has been carefully studied by numerous investigators. M. F. Heddle (see ‹Nature,› Vol. 29, p. 419) assumes the existence of a cavity in a trap rock, which is lined during its solidification with a thin layer of green celadonite or delessite. The rock subsequently rots, and its feldspar is decomposed by water containing carbonic acid, which thus becomes highly charged with silica. This is transfused into the cavity, coagulates and is deposited on its walls. The banded structure is due to the intermittent deposition of successive layers of silica from the highly siliceous solution. It was long supposed that after the earlier layers were deposited fresh supplies of the solution passed inward through a hole called the "inlet of infiltration." This canal is often distinctly seen in agates, but the weight of evidence now seems to favor the hypothesis that the external solution supplies the silica by osmosis (q.v.). The internal solution becomes less dense as it is relieved of silica by its deposition on the walls of the cavity, and it is then replaced by the denser external solution which passes through the layers of agate already formed. If the conditions remain unchanged the process continues until the entire cavity is filled, but agates are not infrequently found with a cavity in the centre, or with crystallized quartz (often amethystine) lining the interior. Such distinctly crystallized portions may be succeeded by further deposits of the cryptocrystalline chalcedony. The successive layers often differ



LOUIS AGASSIZ.

AGATES

1, 4, 5. Carnelian Agate or Sard Agate
3. Onyx Agate 6. Bull's Eye Agate
2. Moss Agate

much in density, hardness, color, and transparency. Sir D. Brewster has shown that some of the layers are so exceedingly thin that it would take 55,760 to measure an inch. (Philos. Mag. (3) XXII., p. 213). These layers are deposited all around the cavities, following all of their irregularities. The beauty of agates is thus greatly enhanced by the extreme delicacy of their banding. Sometimes these bands concentrically encircle a dark spot, forming a «bull's eye agate,» or again they parallel a cavity with sharp angles, as in the «fortification agate.» Other agates show horizontal layers, suggesting the query as to whether the silica had settled upon the floor of the cavity from a solution at rest. Such agates are known as onyx (q.v.), or if the colors are red and white, as sardonyx (q.v.). In clouded agates there is no distinct banded structure, but the colors shade gradually from one into another.

The natural colors of agates vary greatly, being usually gray or either red or brown. The colors are due to the presence of organic impurities or to the oxides of iron, manganese, or titanium. Nearly all the agates now offered for sale are, however, artificially colored. The success of the process is due to the varying degrees of porosity of the different layers of agate, some of which readily absorb the fluid in which the stones are immersed, while others are impervious to it. The black and white agates are prepared by soaking the stones for several days in a warm syrup of honey and water, then immersing them in sulphuric acid, which carbonizes the honey absorbed by certain of the layers, making them dark brown or black. The red, or carnelian agates are produced by a process of «burning.» A grayish stone is heated in an oven for several weeks, at first gently, then it is moistened with sulphuric acid and the temperature is gradually raised to redness. Blue, or «sapphire» agates are produced by steeping the stones first in a solution of a ferric salt and then in postassium ferrocyanide, thus depositing Prussian blue in the more porous layers. A green agate is secured by the aid of chromic acid or a nickel salt, while hydrochloric acid yields a yellow agate. The red and the black are much the most popular.

For over four centuries the headquarters of the agate industry has been in the valley between Idar and Oberstein, some forty miles from Bingen on the Rhine. There are probably 150 agate mills working an average of three to five stones each in this little valley. These are chiefly operated by water-wheels 10 to 18 feet in diameter, abundant power being secured from the rapid mountain streams of the neighborhood. The millstones are of red sandstone, each about five feet in diameter, and rotate in a vertical plane, making about three revolutions per second. The workmen lie stretched in an almost horizontal position upon a low wooden grinding stool fitted to the chest and abdomen, leaving the limbs free. The hands are engaged in holding and grinding the agate, while the feet are firmly pressed against short stakes screwed into the floor, the reaction enabling the grinder to press the agate with much force against the moving millstone. During the process the agates glow most beautifully with a bright red phosphorescence. After having been ground the agates are polished with tripoli on cylinders of wood or a metal disc (see Pop. Sci. Rev., New Series, Vol. I., p. 23).

Moss-agate or «Mocha-stone» is a variety of chalcedony through which are scattered black or brown masses, more or less resembling moss. These impurities are usually one of the manganese oxides. In the Chinese moss-agate they appear as thin matted filaments of a green color, which are often artificially colored. Beautiful dendrites are sometimes found in chalcedony. The name dendritic-agate or tree-agate is given to these highly prized forms (see illustration under MINERALOGY). Moss-agates abound at many localities in the United States, especially in Wyoming.

In the «melaphyre» of the hills around Idar, agates of considerable beauty are found. Formerly they were extensively quarried there, but since 1827 the lapidaries of Idar have secured their supplies largely from Uruguay and Brazil, which countries have long furnished nearly the entire commercial supply, though Scotch agates are marketed to some extent. Small banded agates of much beauty abound on the shores of Lake Superior; large and fine specimens occur plentifully in western Texas. Agates abound in many other regions, while very many localities yield choice agates sparingly. Most of the polished agate specimens and novelties of the tourist resorts, though often purporting to be of local origin, come from Brazil or Uruguay and are polished in Germany.

Agate is used in making burnishers and agate mortars and pestles, and, owing to its hardness, for the knife edges of balances. It is worked up as a decorative stone into vases, dishes, ash trays, paper weights, paper cutters, etc., and is mounted as a semi-precious stone in a great variety of objects, such as jewel boxes, glove or shoe buttoners, watch charms, letter openers, and scarf pins. Every boy is familiar with agate marbles, but the cheaper grades of these are only glass. From the earliest times the black and white banded agate (see ONYX) and the red and white (see SARDONYX) have been used for seal rings and for carving cameos. The ancients also regarded agate as a charm against the intoxication of love.

See also Ruskin, 'On Banded and Brecciated Concretions' in Geological Magazine, 1867 to 1870; 'Ethics of Dust,' p. 190; 'The Vale of Idar,' by S. Weisse in Blackwood's Magazine, Vol. 148, pp. 75 and 208.

GEORGE LETCHWORTH ENGLISH,
Mineralogist, New York City.

Agate-shell, or **Agate-snail**, a land-snail of the carnivorous genus *Achatina* of the family *Helicidæ*. They are abundant in tropical Africa; the largest of all land-snails are found among them, and many species have brightly colored shells.

Agatha, St., a lady of Palermo, martyred by Quintilian, the pro-consul of Sicily, in the persecution of Decius, because she would not perform idolatrous worship or submit to his impure desires.

Agatharchides, ăg-a-thar'kĭ-dēz, or **Agatharcides**, ăg-a-thar'sĭ-dēz, a Greek writer on geography: b. at Cnidos in Asia Minor; lived 250 B.C. and wrote numerous works; among them, one on the Erythræan Sea, of which some extracts have been preserved. He is the earliest extant writer who attributes the annual rise of

the Nile to the periodical rains in the upper regions of that river.

Agathias, a-gā'thi-as, a Greek poet and historian, about 536–581. He collected a ‹ Cycle › of contemporary poems, in which were a few of his own compositions. We have still 101 of his ‹ Epigrams,› and the whole of his ‹ History › of the years 553–558.

Agathocles, ag-ath'ō-klēz, a Syracusan of low extraction, who became ruler of a great part of Sicily. He was remarkable for beauty, strength, and capacity for enduring labor. In the outset of life he belonged to a band of robbers; afterward he served as a private soldier, rose to the greatest honors, and made himself master of Syracuse. He conquered the greater part of Sicily, 317 B.C. Being defeated at Himera by the Carthaginians, he carried the war into Africa, where for four years he extended his conquests over his enemy. He afterward passed into Italy and made himself master of Crotona. In his 72d year he was poisoned by his grandson Archagathus, 289 B.C., after a reign of 28 years of great prosperity mingled with the deepest adversity. His son-in-law, Pyrrhus, king of Epirus, inherited his influence in Sicily and southern Italy.

Agathon, ag'a-thon, a Greek tragic poet (448–402 B.C.). He was a close friend of Euripides and of Plato; and the famous ‹ Symposium › of Plato immortalizes the banquet given on the occasion of Agathon's dramatic triumph, 416 B.C.

Agave, ag-ā'vē, daughter of Cadmus and Hermione, married Echion, by whom she had Pentheus, who was torn to pieces by the Bacchanals. She is said to have killed her husband while celebrating the orgies of Bacchus. She received divine honors after death.

Agave, a genus of remarkable and beautiful herbaceous plants, of the natural order *Amaryllidaceæ*, having a tubular perianth with 6-partite limb, and triangular many-seeded capsule. They resemble aloes in their growth and general appearance, and the best-known species, *Agave americana*, is properly known as the American aloe. This is a large plant, the leaves of which are thick, fleshy, and spinous at the edge, and the stem branched and of great height. The flowers have the tube of the corolla narrowed in the middle, the stamens longer than the corolla, and the style longer than the stamens. This magnificent native of North America is by no means an uncommon plant in English gardens, but is seldom seen there in flower. There is indeed a notion, but an erroneous one, that the American aloe does not bloom until it is 100 years old. The fact is that the time of flowering depends almost wholly on the rapidity of its growth. In hot countries it will flower in a few years, but in colder climates, the growth being slower, it is necessarily longer in arriving at maturity. The stem, which bears the blossoms, rises from the centre of the leaves, and when the plant is in a vigorous state it frequently exceeds the height of 20 feet. Branches issue from every side, and in such a manner as to form a kind of pyramid, composed of greenish-yellow flowers, which stand erect and are seen in thick clusters at every joint. When in full flower its appearance is extremely splendid; and if the season be favorable, and the plant be sheltered from the cold in autumn, a succession of blossoms will sometimes be produced for nearly three months. In the warmer parts of Europe the American aloe is cultivated as an object of considerable utility. They are frequently set out in rows as fences for inclosures, particularly in Spain, Portugal, and Italy. In some parts the leaves are employed for scouring pewter, kitchen utensils, and floors. The juice of these leaves is made into cakes, which are used for washing, and will make lather with salt water as well as with fresh. The sap when fermented yields a beverage resembling cider, called by the Mexicans *pulque*. The leaves are used for feeding cattle; the fibres of the leaves (called *pita*, *sisal hemp*, or *henequen*) are formed into thread, cord, and ropes; slices of the withered flower-stem are used as razor-strops.

Agde, äg-da, a seaport of southern France, dept. He'rault. It possesses a remarkable cathedral dating from the Middle Ages, since when the town has been the seat of a bishopric. Pop. (1902) about 8,000.

Age, any period of time attributed to something as the whole, or part, of its duration; as the age of man, the several ages of the world, the golden age.

In Law, the time of competence to do certain acts. In the male sex 14 is the age when partial discretion is supposed to be reached, while 21 is the period of full age. Under 7 no boy can be capitally punished; from 7 to 14 it is doubtful if he can; at 14 he may. At 12 a girl can contract a binding marriage; at 21 she is of full age. In mediæval times, when a girl reached 7, by feudal custom or law a lord might distrain his tenants for aid to marry, or, rather, betroth her; at 9 she was dowable; at 12 she could confirm any consent to marriage which she had previously given; at 14 she could take the management of her lands into her own hands; at 16 she ceased, as is still the law in England, to be under the control of her guardian; and at 21 she might alienate lands and tenements belonging to her in her own right. In the United States at 25 years of age a man may be a representative in Congress; at 30 a senator; and at 35 he may be chosen President. The age of serving in the militia is from 18 to 45 inclusive.

In England no one can be chosen a member of Parliament under 21 years of age, nor be ordained a priest under the age of 24, nor made a bishop until he has become 30 years of age. The age of serving in the militia is from 16 to 45 years. The sovereignty of the realm is assumed at 18; though the law recognizes no minority in the heir to the throne.

In French Law, a person must have attained the age of 40 to be a member of the legislative body; 25 to be a judge of a tribunal *de première instance;* 27 to be its president, or to be judge or clerk of a *cour royale;* 25 to be a justice of the peace; 30 to be judge of a tribunal of commerce, and 35 to be its president; 25 to be a notary public; 30 to be a juror. At 21 both males and females are capable of performing all the acts of civil life.

Ages of the World.—We find the ages of the world mentioned by the earliest of the Greek poets. Hesiod speaks of five distinct ages: (1) The Golden or Saturnian Age, when Saturn ruled the earth. The people were free from the restraint of laws; they had neither ships nor

weapons, wars nor soldiers; the fertile fields needed no cultivation, and perpetual spring blessed the earth. (2) The Silver Age, which he describes as licentious and wicked. (3) The Brazen Age, violent, savage, and warlike. (4) The Heroic Age, which seemed an approximation to a better state of things. (5) The Iron Age, when justice and honor had left the earth. The poet supposed this to be the age in which he himself lived. The idea of ages of the world is interwoven with the religious sentiments of various nations. We find examples of it in the thousand years of the Millenarians, and in the four *yugas* or ages of the Hindus. The first, or Krita Yuga, a kind of Golden Age, lasted, according to their tradition, 4,000 divine years, each equal to 360 solar years, and, adding its fore and after «twilight,» 1,728,000 solar years in all; men then lived 400 years, and were all giants; then the god Brahma was born. In the second period, the Tretâ Yuga, which lasted 3,000 divine and 1,296,000 solar years in all, men lived only 300 years, and vice began to creep into the world. During the third age, or Dwâpara Yuga, which lasted 2,000 divine and 864,000 solar years, men lived only 200 years, owing to the increase of vice. The last age, the Kâlî Yuga, that in which we now live, is to last for 1,000 divine or 432,000 solar years, and the life of man is sunk to one fourth of its original duration.

Age of Animals.—The duration of life in animals is generally between seven and eight times the period which elapses from birth till they become adult; but this rule, besides being vague and indefinite, is quite useless in practice, because it affords no scale of gradation which would enable us to ascertain the precise age of individuals, the only inquiry of real importance or of practical application to the interests of society. More certain and scientific principles are derived from observing the growth and decay of the teeth. See CATTLE; HORSE.

In Archæology.—The Danish and Swedish antiquaries and naturalists, MM. Nilson, Steenstrup, Forchamber, Thomsen, Worsaae, and others, have divided the period during which man has existed on the earth into three — the Age of Stone, the Age of Bronze, and the Age of Iron. During the first-mentioned of these he is supposed to have had only stone for weapons, etc. Sir John Lubbock divides this into two — the palæolithic, or older, and the neolithic, or newer stone period. At the commencement of the age of bronze that composite metal became known and began to be manufactured into weapons and other instruments; while, when the age of iron came in, bronze began gradually to be superseded by iron. See Lyell's ‹Antiquity of Man,› and Lubbock's ‹Prehistoric Times.›

In Physiology.— If the word age be used to denote one of the stages of human life, then physiology clearly distinguishes six of these: viz., the periods of infancy, of childhood, of boyhood or girlhood, of adolescence, of manhood or womanhood, and of old age. The period of infancy terminates at 2, when the first dentition is completed; that of childhood at 7 or 8, when the second dentition is finished; that of boyhood or girlhood at the commencement of puberty, in temperate climates from the 14th to the 16th year in the male, and from the 12th to the 14th in the female; that of adolescence

extends to the 24th year in the male and the 20th in the female; that of manhood or womanhood stretches on till the advent of old age, which comes sooner or later, according to the original strength of the constitution in each individual case and the habits which have been acquired during life. The precise time of human existence similarly varies. See LONGEVITY.

In Geology.— See GEOLOGY.

Agen, a-zhan, one of the oldest towns in France, capital of dept. Lot-et-Garonne, on the Garonne, 74 m. S.E. of Bordeaux. A fine stone bridge of eleven arches spans the river here, and the aqueduct bridge of the *Canal Latéral* is another striking structure. The town has been an episcopal see with a cathedral since the reign of Clovis, prior to which it was a Roman station. It commands an extensive agricultural trade, owing to its position between Bordeaux and Toulouse. Pop. 1903, 23,000.

Agent, in law, one person who acts for another, called the principal. If a person acts as agent without authority, the subsequent ratification of the act will make it binding on the principal just as if he had originally directed it. When an agent acts within the scope of his employment he may bind his principal, and the principal is liable for any fraudulent acts or wrong-doings of the agent so acting. If the agent, having power to bind his principal, does so expressly, he is not liable; but if he exceeds his authority he becomes personally responsible. The agent is bound to obey the instructions of the principal, and if, in violating them, he binds his principal to a third person, he is personally liable to make compensation. He cannot deal in his principal's affairs to his own profit. The right on the part of an agent to act is called his authority or power. The authority or power must in some instances be exercised in the name of the principal, and the act done is for his benefit alone. As a general rule, an agent cannot delegate his authority without special authority from his principal, consequently an agent cannot create a sub-agent without special permission. Any person may act as agent whom the principal wishes to appoint. So broad is this rule that married women and infants, who are incapable of acting in their own behalf, may act as agents, for the appointment takes away the legal insufficiency and permits them to bind their principals when they could not bind themselves. The mode of appointment depends upon the nature of the agency. By a rule of law the evidence of appointment must be of as high a nature as the thing to be done. Thus, to execute a writing under seal, the appointment must be under seal. When the authority or power is coupled with an interest, or when it is given for a valuable consideration, or when it is a part of a security, then, unless there is a special agreement that it shall be revocable, it cannot be revoked. Death, insanity, bankruptcy, the extinction of the subject-matter of the agency, or the execution of the trust, will usually terminate the agency unless the authority is coupled with an interest. Upon the law of agency is based to a large degree the law of partnership.

Age of Chivalry, The, or **The Legends of King Arthur,** by Thomas Bulfinch, was published in 1858. More than 20 years after, an enlarged edition appeared under the editorship of

Edward Everett Hale. In Part First the legends of King Arthur and his knights are considered. Part Second deals with the Mabinogion, or ancient prose tales of the Welsh; Part Third with the knights of English history, King Richard, Robin Hood, and the Black Prince. From the time of its first publication the popularity of the book has been great. No more sympathetic and fitting introduction could be found to the legends of chivalry.

Age of Fable, The, or **The Beauties of Mythology,** by Thomas Bulfinch, was published in 1855, and republished in 1882 under the editorship of Edward Everett Hale. It has become a standard work upon mythology, by reason of its full and extensive treatment of the Greek and Roman myths.

Age of Reason, The, by Thomas Paine, was first published in a complete edition 25 Oct. 1795. In 1793 the First Part appeared, but no copy bearing that date can be found. Part First consists of an inquiry into the bases of Christianity, its theology, its miracles, its claims of revelation. The process is destructive and revolutionary. In Part Second the author makes critical examination of the Old and New Testament, to support the conclusions and inferences of Part First. Yet the work is not wholly negative. «The Word of God is the creation we behold.»

Ageratum, a-ger'a-tum, a genus of plants of the natural order *Compositæ* (belonging to the Eupatorium tribe of the order), natives of the warmer parts of America. One species, *A. mexicanum,* is an annual plant of flower borders and has densely clustered capitula of lavender-blue flowers. Several others are also grown in gardens, some of them with purple, white, or pale blue flowers. One of these, *A. conyzoides,* has sky-blue or gray-blue flowers and flower-heads almost conical in form. This species, with *A. littorale,* grows wild in southern Georgia, and in Florida.

Agesila'us, a king of Sparta: b. 442 B.C., and elevated to the throne after the death of his brother Agis II., in 398. Called by the Ionians to their assistance against Artaxerxes, he commenced his glorious career by defeating the Persians and defending Sparta against the united attack of Thebes, Corinth, etc. In a subsequent war with Thebes he had to contend against Pelopidas and Epaminondas, the greatest generals of those times. His prudence, however, saved Sparta without the hazard of a battle. He delivered it anew at the age of 80 years, though it was actually in the hands of Epaminondas. In the spring of 361 he crossed over to Egypt with a body of Lacedæmonian mercenaries, and there, after displaying much of his former ability, he died while preparing for his voyage home, in the winter of 361–360. Though small and insignificant in person he was a noble prince and almost adored by his soldiers.

Agglomerate, in geology, a name applied to a rock consisting of angular fragments of other rocks, united or bound together by a matrix of similar materials but of finer texture. The rock is of volcanic origin, but the fragments may be either volcanic or sedimentary, having been ejected from some volcano.

Agglutinate Languages, languages in which the modifying suffixes are as it were glued on to the root, both it and the suffixes retaining a kind of distinctive independence and individuality, as in the Turkish and other Turanian tongues. (See Max Müller's ‹Lectures on the Science of Language.›)

Agglutination. See IMMUNITY.

Aggregation, States of, an expression sometimes used to signify, collectively, the various physical states in which matter can exist. For ordinary purposes it is sufficient to distinguish two fundamentally different states of aggregation, the solid and fluid; fluids being further subdivided into liquids and gases. A solid body may be defined as one that is capable of resisting a considerable shearing-stress. It is important to note, however, that a true solid does not yield continuously to a small deforming force; it resists deformation, and its resistance increases as the deformation increases. A fluid, on the contrary, is a body having almost no shearing-strength, and offering very little resistance to forces that tend to change its shape. A fluid yields continuously to a deforming force, and a force that will deform it at all will deform it indefinitely, so long as it is allowed to act. Considering the subdivision of fluids into gases and liquids, it may be said that a gas is a fluid that presses continuously and in every direction on the walls of the vessel containing it, and which follows them indefinitely if they retreat. A gas, if left to itself, tends to expand infinitely in every direction. A liquid may be defined as a fluid which does not follow the walls of the containing vessel if they retreat, and which has no tendency to sudden and indefinite expansion when freed from all restraint.

These distinctions between the various states of aggregation in which matter occurs are to a certain extent arbitrary, elastic, indefinite, and inexact. For example, certain kinds of pitch resist the action of deforming forces that are applied for a short time only, and are brittle enough to fracture, like glass, under the influence of a sudden stress; yet they yield slowly but continuously to very small deforming forces, when those forces act for a long time. A body of this sort, strictly speaking, is neither a solid nor a liquid, and to include it in a general classification we should have to have a «semi-solid» division. The distinction between liquids and gases is even more artificial than that between solids and liquids; for a liquid may be made to pass into its vapor in such a manner that it is impossible to state at what moment it ceases to be a liquid. Thus, if water is heated under a sufficiently great pressure up to 700° F., and is then allowed to expand by a sufficient amount at this temperature, and is finally cooled at constant volume, we shall find, at the end of this operation, that it has been entirely transformed into steam, although we cannot say at what stage the transformation took place. See CRITICAL POINT; EQUILIBRIUM (*Chemical*); MOLECULAR THEORY; THERMODYNAMICS; MATTER.

Agincourt, ăj'in-kōrt, or **Azincourt,** ä-zhäṅ-koor, France, a village, dept. Pas-de-Calais, famous for a battle fought there 25 Oct. 1415. Henry V., king of England, eager to conquer France, landed at Harfleur, took the place by storm, and wished to march through Picardy

to Calais, in order to fix his winter quarters in its neighborhood. With a powerful force the Dauphin advanced against him. Henry V. retreated to the Somme. The French followed to harass his retreat and to defend the passage from Abbeville to St. Quentin, which he gained only through the inattention of the enemy. The English, however, being destitute of everything and reduced by sickness, Henry asked for peace on disadvantageous terms. The French refused his proposals, and succeeded in throwing themselves between Calais and the English. These latter consisted of 2,000 men-at-arms and 12,000 archers, and were arranged in order of battle between two hills, with the archers on the wings. Stakes, of which every man carried one, were fixed in front of them. The French, commanded by the Constable d'Albret, numbered 50,000 troops, of whom 8,000 were men-at-arms; but other estimates make the French strength much greater. They arranged themselves in two divisions, with the men-at-arms, of whom 2,000 were mounted, in front. The English first put themselves in motion. The French horse instantly hastened to meet them, but were received with such a shower of arrows by the archers that they fell back on the first division, and threw it into confusion. The light-armed English archers seized their clubs and battle-axes and broke through the ranks of the French knights, who could hardly move on account of their heavy coats of mail and the closeness of their array. The English horse rushed to assist the archers; the first French division retreated; the second could not sustain the charge of the victors; and the whole French army was soon entirely routed. The victorious army, in the pursuit of the flying enemy, took 14,000 prisoners in addition to those previously captured; 10,000 Frenchmen lay dead on the battle-field. Among them was the Constable of France, with six dukes and princes. Five princes, among whom were the Dukes of Orleans and Bourbon, were taken prisoners. The English lost 1,600 men killed; among them the Duke of York, Henry's uncle, whom the Duke d'Alençon slew at his side while pressing toward the king. D'Alençon had dashed the crown from Henry's head, and lifted his hand for a more effectual blow, when the king's attendants surrounded him and he fell covered with wounds.

Agis, ā'jis, the name of four Spartan kings. Agis I., son of Eurysthenes, founder of the family Agidæ, and reputed conqueror of Helos. Agis II., son of Archidamus II., and reigned either in 427 or 426 B.C. to 400 or 399 B.C. He was active in the Peloponnesian war; invaded Attica several times; and conquered the Athenians at Mantinea in 418 B.C. Agis III., son of Archidamus III., reigned in 338–1 B.C. He endeavored to overthrow the Macedonian power in Europe, but was routed and killed in a battle with Antipater in 331 B.C. The most important of the four kings was Agis IV., who succeeded to the throne in 244 B.C., and reigned four years. He attempted a reform of the abuses which had crept into the state — his plan comprehending a redistribution of the land, a division of wealth, and the cancelling of all debts. Opposed by his colleague, Leonidas, advantage was taken of his absence in an expedition against the Ætolians to depose him. Agis at first took sanctuary in a temple, but he was entrapped and hurriedly executed by his rivals.

Aglossa, ā-glos'sa (Gr. *a*, priv.; *glossa*, tongue), a group of the order *Anura* (toads and frogs) containing only two living families, the South American *Pipidæ* and the African *Xenopidæ*, and characterized by the lack of any tongue and the union of the eustachian tubes into one opening far back in the palate. The pipa toads and South African plathandlers are typical examples. The group is interesting for its antiquity and primitive relationships.

Agnadello, an-ya-del'lo, North Italy, a village 10 m. E. of Lodi, near which Louis XII. of France completely defeated the Venetians, on 14 May 1509, and the Duke of Vendome gained a victory over Prince Eugene in 1705.

Agnano, an-yä'no, till 1870, a small lake, 3 m. W. of Naples, about 60 ft. in depth, and without visible outlet. As it was supposed to cause malaria it has been drained. The surrounding country is volcanic and mountainous. On the right lies the Grotta del Cane, where the carbonic acid is dense enough to kill dogs, and on the left are found the sulphurous vapor baths of San Germano, which are valuable for gout and blood disorders.

Agnes, Saint, a saint who, according to the received account, because she steadfastly refused to marry the son of the prefect of Rome and adhered to her religion in spite of repeated temptations and threats, suffered martyrdom during the persecution of the Christians in the reign of the Emperor Diocletian, 303 A.D. She was first led to the stake, but as the flames did not injure her she was beheaded. Her festival is celebrated on the 21st of January. Domenichino painted a picture representing her at the moment of her execution.

Agnesi, â-nyā'sē, **Maria Gaetana,** a learned Italian lady: b. in Milan in 1718. In her 9th year she was able to speak Latin, in her 11th Greek; she then studied the Oriental languages, and next geometry and philosophy, mathematics having latterly engaged her chief attention. She was appointed, in 1750, professor of mathematics in the University of Bologna, ultimately took the veil, and died in 1799. Her sister, Maria Theresa, composed several cantatas and three operas.

Agnes of Sorrento, a romance by Harriet Beecher Stowe. The scene is laid in central Italy during the papacy of Alexander VI. (1492–1503). Agnes is the daughter of a Roman prince who secretly marries and then deserts a girl of humble parentage. The young mother dies of grief, and Elsie, the grandmother, takes Agnes to Sorrento, where she lives by selling oranges in the streets. Her beauty and her purity attract to her many lovers, worthy and unworthy, and involve her in many romantic and dramatic incidents.

Agnew, Cornelius Rea, an American physician: b. New York 8 Aug. 1830; d. 8 April 1888. Professor of diseases of the eye and ear in New York College of Physicians and Surgeons. He was a graduate of Columbia College, and later studied in Europe; was surgeon-general of the State of New York at the beginning of the Civil War, when he became medical director of the New York State Volunteer Hospi-

tal. As member of the United States Sanitary Commission he contributed largely to its success. In 1868 he founded the Brooklyn Eye and Ear Hospital. He was interested in the public schools of New York; became founder of the Columbia College School of Mines, and in 1874 one of the trustees of the college. His writings are chiefly monographs on diseases of the eye and ear.

Agnew, David Hayes, an American surgeon and medical writer: b. 24 Nov. 1818; d. 22 March 1892; for many years professor of surgery at the University of Pennsylvania. He was also the operator in several important cases, notably that of President Garfield. He published 'Practical Anatomy' (1867); 'Anatomy and Its Relation to Medicine and Surgery'; 'Principles and Practice of Surgery' (1878); etc.

Agno, ag'nō, an important river in the N.W. part of Luzon, Philippine Islands. It is about 90 m. in length, describing a circuitous course, parallel with a range of coast mountains, and emptying into Lingayen Gulf. The town of Lingayen is at the mouth of the river, which is accessible by railway from Manila.

Agnosticism (Gr. "unknowing"), a school of thought which holds that man can know nothing of ultimate realities, or whether they exist; since, his only means of knowledge being through comparison of phenomena, the absolute could only be cognized by his senses on assuming phenomenal traits, and would then be grasped as a phenomenon and not as absolute, the knowledge of which is therefore a contradiction in terms. We cannot know anything outside our own mental processes and the existence of other minds; in popular phrase, we cannot get behind the looking-glass. This does not, however, deny the absolute any more than affirm it; and most agnostics (as Clifford, one of the greatest) consider the diversity of phenomena as probably indicating a diversity in their causes. The agnostic position involves refusal to accept "evidences" of the origins of the universe, of unseen powers, of a future life, or in general the metaphysical bases of religion, save as more or less probable inferences. The current idea that it involves rejection of these beliefs, however, is entirely wrong: the agnostic does not admit that either the affirmative or the negative of them can be a subject of knowledge, and regards the atheist as less intellectually respectable than the devotee. In point of fact, Prof. Huxley, the inventor of the term, thought the existence of beings higher than man rather probable than otherwise, and the government of the universe by a "divine syndicate" of great spiritual essences quite logical. The greatest of modern agnostics was Herbert Spencer. The theory is practically that of the Pyrrhonist or Skeptical school of Greek philosophers.

Agnus Dei. See SACRAMENTALS.

Agosta, or **Augusta**, a seaport on the S.E. coast of Sicily, in the province of Syracuse, and 12 m. N.N.W. of the city of that name. It was a place of some importance before the earthquake of 1693, which buried a third of the inhabitants in its ruins, and at the same time by supposed sulphurous vapors which issued from the ground, ignited the powder magazine, and blew up the citadel. It was off this port that De Ruyter, the famous Dutch admiral, in command of the united Dutch and Spanish fleet, 22 April 1676, was defeated by the French under Duquesne, and received his death wound. Pop. about 12,500.

Agra, ä'gra, India, a city in the Northwest Provinces, on the right bank of the Jumna, 841 miles by rail from Calcutta. It is a well-built and handsome town and has various interesting structures, among which are the imperial palace, a mass of buildings erected by several emperors; the Moti Masjid or Pearl Mosque (both within the old and extensive fort); the mosque called the Jama Masjid (a cenotaph of white marble); and above all, the Taj Mahal, a mausoleum of the 17th century, built by the Emperor Shah Jehan to his favorite queen, of white marble, adorned throughout with exquisite mosaics. There are several Protestant and Roman Catholic churches, a government college, and three other colleges or high schools, besides a medical college. Agra has a trade in grain, sugar, etc., and some manufactures, including beautiful inlaid mosaics. It was founded in 1566 by the Emperor Akbar, and was a residence of the following emperors for over a century. Pop. 168,662. The Agra division has an area of 10,139 square miles, and a pop. of 4,767,759.

Agrarian Laws, enactments framed at different times by the Romans to regulate the public domain. In the first epoch of the growth of Rome, before the city had extended beyond the Palatine Hill, the whole soil of the state was undivided public property, and from the state, consisting exclusively of citizens, every citizen received a share for his private use. In principle all the land was therefore undivided public property, and the citizen could only acquire possession as tenant at will of the state. In course of time, however, the descendants of the original founders, or the patricians, transformed these primitive concessions into an absolute right called in the Roman law *de jure quiritio*. During the entire existence of the republic the principle was recognized that all lands and personal property acquired by conquest were acquired for the state, and could only become the property of individuals through the cession to them of the rights of the state. As conquest increased the public property, and the class of plebeians was formed, the Roman government gave them an interest in the public domain as private property on condition of their paying a tribute and undertaking other public services. The patricians, however, always preserved their ancient right of receiving in possession and using portions of the public property on paying to the public treasury a tithe of its product. From the earliest period of Roman history lands thus held could pass as an inheritance to children, and were even sold under this uncertain tenure, while the state always reserved the power to resume possession. Spurius Cassius, a patrician, on becoming consul in the early period of the republic, caused a law to be enacted that some portion of the public lands, long before conquered, but occupied by the Roman nobles, should be surrendered to the state and assigned to the needy citizens. The law remained a dead letter because of the resistance of the patricians, who not only prevented any new divisions of the public lands, but by violence or usury acquired

those of the plebeians. The keeping of large flocks of cattle practically ruined the common pasture lands, and in fact excluded the small farmers from them. This caused the publication, in 367 B.C., of the Licinian law, so called from Licinius Stoto, its originator. For a brief period this law was put in force, after which it was neglected for nearly 200 years, when it was renewed by Tiberius Gracchus with some additions and modifications in favor of the patricians. The attempt to execute these laws caused the death of the two Gracchi (133 and 121 B.C.). Not one of the Agrarian laws was ever executed, and it is said by the ablest writers that they had none of that leveling and confiscatory character which has been so often attributed to them. It is believed by able writers that none of the laws aimed at the equal division of real estate owned by individuals in their own absolute right, or intended any limitation upon the ownership of land. The most prominent advocates of the Agrarian laws, Cassius, Licinius, and the Gracchi, all belonged to the class which would have been injured by their operation had they led to an undue interference with the right of private property.

Agrarian Party, a political organization in Germany, representing the interests of the landlords (in political life). The first steps toward the formation of the party were taken by an assembly called together at Breslau, in May 1869, by M. A. Niendorf (d. 1878), and Elsner von Gronow, but the theory on which the party was based had already been formulated by Johann Karl Rodbertus. The organ of the party was *Die Deutsche Landeszeitung*, edited by Niendorf. In February 1876 a constitutional assembly of agrarian reformers was opened, and adopted the official name of "Steuer und Wirtschaftreformer." Their programme was especially devoted to the abolition of taxes on land, buildings, and trades. At first especial emphasis was laid on free trade, but this object fell more and more into the background after 1879. Since that date they have sought to limit the importation of food stuffs, and have opposed several commercial treaties supported by the government; they have also opposed the emperor's project for a canal system, and have been hostile to his navy policy. As the Agrarians dominate the Conservatives in the Reichstag they have frequently obtained important concessions in commercial matters and forced the government to turn to the Radicals for support for its measures.

Agreement, a mutual bargain, contract, or covenant. Agreements may be either express or implied. Express agreements are those openly stated and avowed by the parties at the time of their making. Implied agreements are those which the law supposes the parties to have made although the terms were not openly expressed.

There must be an agreement by the parties, a definite offer made by one party and accepted by the other, and they must assent to the same thing in the same sense. The assent must be mutual and obligatory, and there must be a request on one side and an assent on the other. The assent must be broad enough to cover the whole proposition. It must be exactly equal to its extent and provision, and it must not qualify them by any new matter, and even a slight qualification destroys the assent. The agreement must be based upon a sufficient consideration (q.v.), and as against third persons this consideration must be good or valuable. It need not be adequate provided it has some real value. If the consideration is impossible, or illegal either in whole or in part, the agreement will be void. The agreement may be to do anything permitted by the law, as to sell and buy real estate or personal property. The evidence of the sale of real estate, however, must be by deed, and sealed. In many instances agreements in regard to personal property must be reduced to writing. See CONTRACTS.

Agric'ola, Cneius Julius, lived from A.D. 37 to 93, and was a Roman general and governor in Britain, the greater part of which he brought under the dominion of Rome. His life (which extended through the reigns of the nine emperors from Caligula to Domitian) has been excellently written by his son-in-law, Tacitus, who holds him up as an example of virtue. Agricola was born at Forum Julii (now Fréjus in Provence), and was the son of Julius Græcinus, a senator put to death under Caligula. He served his first campaign in Britain in 60, and after serving in Asia Minor and again in Britain, and governing Aquitania as prætor for three years, he was raised to the consulship in 77, and the next year went to Britain as governor. Agricola was the twelfth Roman general who had been in Britain, but was the only one who effectually subdued it; partly by his consummate military skill, partly by his policy in reconciling the Britons to the Roman yoke, and by teaching them the arts and luxuries of civilization. In his fourth campaign he built a chain of forts between the Forth and Clyde to help to keep in check the peoples to the north of this. His seventh and last campaign (A.D. 84) was marked by the total defeat of the Caledonians under Galgacus, at some place called by Tacitus *Mons Grampius* or *Graupius*. In this campaign his fleet sailed northward from the coast of Fife round Britain to the Trutulensian harbor (supposed to be Sandwich), thus for the first time proving that the country was an island. His death was either caused or hastened by the minions of the jealous tyrant Domitian.

Agricola, Johann, German reformer: b. 1492; d. 1526. He was one of the most active among those who propagated the doctrines of Luther. He studied at Wittenberg and Leipsic; was afterward rector and preacher in Eisleben, his native city, and in 1526, at the Diet of Spires, was chaplain of the Elector John of Saxony. He subsequently became chaplain to Count Albert of Mansfield, and took a part in the delivery of the Confession of Augsburg, and in the signing of the articles of Schmalkalden. When professor at Wittenberg, whither he went in 1537, he stirred up the Antinomian controversy with Luther and Melanchthon. He afterward lived at Berlin, where he died after a life of controversy. Besides his theological works he composed a work explaining the common German proverbs. Its patriotic spirit, strict morality, and pithy style, place it among the first German prose compositions of the time, by the side of Luther's translations of the Bible.

Agricola, Rudolphus, the foremost scholar of the "New Learning," in Germany: b. 23 Aug. 1443, near Groningen, in Friesland; d. 28 Oct. 1485. His real name, Roelof Huysmann (husbandman), he Latinized into Agricola; and from his native place he was also called Frisius, or Rudolf of Groningen. From Groningen he passed to Louvain, then to Paris, and then to Italy; where, during the years 1473–80, he attended the lectures of the most celebrated men of his age, and where he entered into a close friendship with Dalberg, afterward Bishop of Worms. On his return home he endeavored, in connection with several of his former co-disciples and friends, to promote a taste for literature and eloquence. Several cities of Holland vainly strove with each other to obtain his presence, but not even the brilliant overtures made to him by the Emperor Maximilian, to whose court he had repaired in connection with affairs of the town of Groningen, could induce him to renounce his independence. At length yielding (1483) to the solicitations of Dalberg, he established himself in the Palatinate, where he sojourned alternately at Heidelberg and Worms, dividing his time between private studies and public lectures, and enjoying high popularity. He distinguished himself also as a musician and painter. With Dalberg he revisited Italy (1484), and shortly after his return died at Heidelberg. Most of his works were collected by Alard of Amsterdam (2 vols. Cologne, 1539).

Agric'olite, a mineral having the same composition as eulytite, but crystallizing in the monoclinic system. It also occurs in globular forms, with a radiated structure, and the crystals, when they occur, are indistinct. The species needs further examination.

Agricultural Ant, a remarkable species of ant (*Myrmica molefaciens*) that cultivates fields of grass around its hill, allowing only one kind of grass (*Aristida*) to grow in a field; it harvests the seeds and stores them away as food. The fields may be as large as 15 feet across; roads are laid out from the hill to the outer margin of the plantation, so that the crop may not be trampled, and any weeds which appear among the grass blades are at once cut off. These colonies are often found in large grain fields, which they injure in proportion to their numbers.

Agricultural Chemistry is the science upon which scientific agriculture is built; the chemistry of the atmosphere, of the soil, of manures, of plants, and of animals, describe and explain in large part the phenomena of plant growth and of the transformation of plants into animal products. The basic facts which the investigations of agricultural chemists have revealed, and which serve as the foundation upon which the facts derived from further investigation must rest, may be stated as follows:

Sources of Plant Food.—The atmosphere and the soil are the two sources from which plants obtain their food. The atmosphere supplies the plant, either directly or indirectly, with carbon, hydrogen, oxygen, and nitrogen; the carbon mainly directly in the form of carbon-dioxid, the hydrogen and oxygen indirectly in the form of water in the soil, which is absorbed by the roots of plants, and nitrogen mainly indirectly in the form of nitrates in the soil, which is also taken up by the roots of plants. The soil is the only source of the mineral elements used by the plant, and those essential for its growth are potassium, magnesium, calcium, iron, chlorine, sodium, phosphorus, and sulphur, though others may be present in the plant as accidental salts; as, for example, silicon, manganese, boron, etc. These mineral elements are obtained from the soil by means of the plant roots.

Constituents of Manures.—While plants require and use a relatively large number of chemical elements for their perfect development, those essential in manures are limited to four, namely, nitrogen, phosphorus, potassium, and calcium, for the reason that these are contained in the soil in relatively small amounts, and are required by plants in relatively large amounts. Exhaustion of soil means the exhaustion of one or more of these four constituents, which measure the potential fertility, and a direct manure is a substance which contains one or two, or all of these.

The Composition of Plants.— In all normal plant growths there are four distinct classes of substances, namely, albuminoids, fats, carbohydrates and mineral salts, each of which as a class exercises a special function in the nutrition of animals. The varying proportions of these substances in the different plants also determine the value of any plant as a source of any specific substance for commercial purposes; as, for example, sugar or oil.

The Composition of Animals.—The animal body consists of three classes of substances, namely, nitrogenous matter, fatty matter, and mineral salts; these are derived from, and are similar in character to, the same classes of substances in plants. These statements of the basic principles of plant growth and use clearly indicate the important role that agricultural chemistry may exercise in the many directions in which it may be applied in the development of scientific farm practice. It indicates the broad field of agricultural chemistry; and agricultural chemists, because of the many important special lines of inquiry, are classified as soil chemists, fertilizer chemists, food chemists, sugar chemists, agricultural industrial chemists, etc., according as they give special attention to any one of these particular branches.

Methods of Analysis.—The application of chemistry in these various directions, has in recent years been accompanied by a development in analytical and research methods, both in the devising of new apparatus and new methods for the analyses of new materials, and in the improvement of the apparatus and the methods already in use.

The Association of Official Agricultural Chemists, organized in 1880, which at first included only the American chemists engaged in the official analytical control of commercial fertilizers, gave the initial impetus to a movement which has been largely responsible for the progress of agricultural chemistry in this country. This organization has gradually broadened its work, and now includes, as members, analysts and specialists in all the various lines of agricultural chemical work. To this association is reported annually the investigations that have been made by its members in the testing of new

and in the improvement of old analytical methods. The good results of such work are particularly noticeable in the adoption of uniform methods in the different laboratories, either new, or modifications of those standard methods devised by the earlier investigators. The crude apparatus and the tedious methods of 25 years ago, which are still in use in many foreign laboratories, have in this country been supplanted by those which ensure not only greater accuracy, but greater rapidity of execution. These improvements have made it possible for the chemists to perform the large number of analyses now required in the official control of commercial fertilizers, of commercial foodstuffs, and of dairy products.

The Study of the Sources of Nitrogen to Plants.— The most important contribution made to science by agricultural chemists in recent years has been in the study of the sources of nitrogen to plants. The experiments of Berthelot, Helriegel, Wilfarth, and others in Europe, and of Atwater in America, have modified the views originally held in reference to this subject. That the chief source of nitrogen to plants is mainly directly from the soil in the form of nitrates is not disputed, but the experiments referred to have shown that the leguminous plants, such as peas and beans, have the power of obtaining the free nitrogen of the air, and thus both soil and air contribute to their supply of this element. It has been shown that this absorption of free nitrogen is not performed directly, but the fixation is the result of the joint action of certain micro-organisms present in the soil and in the plant itself; that this fixation is connected with the formation of tubercles on the roots of this class of plants, and that these may be the home of the fixing organisms, which are not present in all soils. In other words, the fact has been established that these plants do obtain their nitrogen from the air, a source inaccessible to other classes of plants, though the exact method and the complete phenomena involved in its appropriation are not yet understood; these points are matters under investigation at the present time.

Denitrification.— Denitrification, or loss of nitrogen from soils and manures by the reduction of the nitrates and the setting free of the nitrogen, is another rather new though closely related phase of the nitrogen question which is receiving the attention of agricultural chemists. Denitrification is also due to organisms contained in manures and in soils, and the question involves the study not only of the organisms themselves, but of their food and the conditions which favor or retard their growth. The experiments conducted thus far both in Europe and in America indicate that good conditions of soil management do not favor the activity of these organisms, and that losses due to denitrification are greatest where drainage, cultivation, and management are neglected.

Chemical Investigation of Soils.— Chemical investigations have shown that the active fertility of soils depends both upon the amount of the essential constituents present, and the mutual reactions of the various classes of substances which constitute their bulk. Chemical studies have been directed toward separating these substances, and to the discovery of their relations to each other. The combined study of the influence of the chemical and physical properties of soils in encouraging changes in the chemical form of the constituents, and in their absorptive and retentive power for both water and plant-food, has resulted in showing the adaptation of certain classes of soils to specific crops, and has made it possible to indicate clearly the line of profitable culture.

Further important results of studies in recent years have had their origin in the discovery that micro-organisms living in the soil exert a decided influence in changing its chemical character, and in contributing to active fertility. It has been established that, other things being equal, soils are fertile in proportion as the physical and chemical conditions are favorable for the growth and development of those living forces. This fact has encouraged the chemical study of the various classes of soil substances as sources of supply of food for these lower organisms, and the knowledge gained has contributed materially to the development of methods of soil improvement.

Farm Manures.—The question of the function of natural agencies in promoting fertility is closely related to that of manures, fertilizers, and soil amendments. Chemical studies of the character and value of farm manures as sources of plant food, of the source of loss of the valuable constituents, especially nitrogen, contained in them, and the methods of preservation and use of the various materials, have established the important facts that practically 80 per cent of the fertility elements contained in food are found in the manure, and that more than one half of the nitrogen and practically all of the potash contained are in soluble forms. These constituents are readily available as food to plants, comparing favorably with best artificial supplies, but are liable to suffer great loss, the former by fermentation and leaching, and the latter by leaching. This may be prevented by proper care and the use of preservatives.

Fertilizers.— As to the artificial supplies of plant-food, chemical studies have been mainly directed toward the determination of the availability of the different constituent elements contained in the various sources of supply. Nitrogen, for example, shows varying degrees of availability: with nitrate at 100 per cent as a basis, the range is from 80 per cent in dried blood to as low as 2 per cent for leather. These wide variations in agricultural value are not accompanied by variations in commercial value, hence studies have been made of chemical methods for the determination of the availability of nitrogenous substances in mixed fertilizers, in which it is otherwise impossible to detect their source, and such progress has been made as to enable chemists by the use of these methods to indicate the relative value of the materials used. Much study has also been given to the question of the relative availability of the phosphoric acid as found in the various raw and manufactured supplies, and positive information can now be given as to the best sources of supply for specific crops and for special kinds of soil.

Lime, Marl, and Other Soil Amendments.— The purpose of the use of these materials is mainly to supply the plant indirectly with its needed constituents, and careful investigations have shown that lime, for example, while not usually a deficient constituent, performs very

important functions in the improvement of soil: first, in correcting acidity, and thus making the soil a better medium for the growth and development of soil organisms; second, in acting chemically on organic matter and on phosphatic and potash compounds in the soil, and setting free their constituent elements; and third, in changing and improving the physical character of soils. Notable studies along this line have been carried out in this country, particularly by Wheeler in Rhode Island, and the results of such investigations have done much to promote the growth of leguminous crops, which add to the soil humus-forming material containing nitrogen; the humus exerting an important function in increasing the absorptive and retentive powers of soils.

The Composition and Nutritive Value of Plants.— Recent chemical investigations have also resulted in securing more definite information concerning the approximate composition of plants. It is now possible to classify clearly the nutritive substances contained in any specific crop, and to determine the composition of the various chemical substances in the same group. In the group albuminoids, for example, methods of analysis have been developed which enable a separation of the various nitrogenous bodies contained in it, and which show their relative nutritive value. Very important studies of this group have been carried out by Osborne in Connecticut: those in the use of the respiration apparatus, in the studies of human nutrition, by Atwater, and of animal nutrition, by Armsby, have already contributed materially to our sum of knowledge concerning the energy value of various nutritious bodies. These results have their application in the utilization of wastes and in the selection and preparation of rations and of dietaries, furnishing a rational basis for the selection, combination, and preparation of foods.

The Chemical Improvement of Plants.—The improvement of plants, not only for use directly as food, but as sources of supply of specific compounds for special manufacture, has been very marked in recent years. The chemical study of the sugar-beet, of sugar-cane, and of sorghum, has resulted in the development of varieties which are much richer in sugar than formerly, and poorer in non-sugars, the substances which interfere with the extraction and crystallization of the sugar. So also the chemical study of maize, combined with the selection of seed, has enabled the building up of varieties which possess a larger than normal proportion of either carbohydrates, the fats, or the nitrogenous matter, thus improving this most useful plant for the purpose of the manufacture of starch or as a source of oil, or for use as food for live stock. The increase in the gluten content of wheat for the flour manufacturer, the improvement of barley for the brewer, are also the direct result of chemical supervision in the growth of these plants.

The Chemistry of Dairy Products.— The agricultural chemist has also been active in the study of the composition and character of the milk of different dairy breeds as sources of food supply, as well as the processes involved in the manufacture of butter and cheese. Quick and accurate methods for determining the percentage of the important constituent fat have been developed, and valuable results have been secured in the study of the changes that take place in the manufacture of cheese. The most important recent discovery is that of Russell and Babcock of Wisconsin, that enzymes cause the breaking down of the nitrogenous bodies of the milk, and that they, together with bacteria, are factors to be considered in the curing of cheese.

History.— As a science it was born only a century and a quarter ago. The composition of the soil was then unknown, and its relation to plant-growth, with the true function of fertilizers, a matter of crude and blundering empirics. It is interesting to note that Lavoisier, who did so much to create the general science, formulated also its agricultural application with striking accuracy, saying that the components of plants « in the last analysis are drawn from the air and the mineral kingdom. On the other hand, fermentation, putrefaction, and combustion continually restore to these the principles borrowed from them by plants and animals.» Sir Humphry Davy, following Lavoisier's indications with zeal, was the first great chemist to make agricultural chemistry a special study and write upon it, delivering a course of lectures before the British Board of Agriculture about 1800, and embodying them in a volume. Many of his hypotheses were erroneous, but he greatly advanced the science.

As early as 1807 Count Rumford observed that plants deprived of carbonic acid die; and soon afterward Ingenhousz proved that they absorb it only under the influence of sunlight. These facts led to the great generalization, the basis of scientific agricultural chemistry, that plants live mainly on inorganic matter.

During the second quarter of the century the distinguished French chemist Boussingault devoted himself almost wholly to agriculture, publishing many papers on it, his ‹Rural Economy› (1844) giving him a European reputation; and the second De Saussure (d. 1845) wrote 36 valuable papers on vegetable physiology, collected as ‹Chemical Researches on Vegetation.› But the great era in the science was made by Justus von Liebig, who published in 1840 a famous work entitled ‹Organic Chemistry in its Relation to Agriculture,› translated into several languages and of enormous influence. He had great gifts of exposition; and he established in the popular mind the theory of the plants' almost entire dependence on mineral food, hitherto held only by a few men of science. Further, his researches founded artificial fertilization — that is, the use of chemically-prepared fertilizers; and showed how to make the phosphoric acid in mineral phosphates available by treatment with sulphuric acid. He also demonstrated the value of potash as plant food. He taught that the nitrogen was absorbed solely as ammonia: a view much modified by later researches.

The publication of his experiments made a profound impression, and paved the way for the establishment of experiment stations (q.v.), and in the United States led to the formation of the Agricultural Division of the Patent Office, since developed into the Department of Agriculture.

The work of Pasteur showed that fermentation was due to living organisms, thus revo-

lutionizing the whole theory of organic decay. One important practical application of this discovery was the possibility of preserving food by heat sterilization.

Liebig's theory of nitrogen assimilation by plants was fully demolished only by the discoveries of a few years ago, consequent on Pasteur's, that the proteid matter furnishing the bulk of nitrogenous plant foods is changed by ferments successively into ammonia, nitrous acid, and nitric acid, in which form it is directly assimilated.

As the nitrogenous foods are far the most expensive of all essential manures this discovery is vital to agricultural progress. The Chilean and other South American stores of nitrates are not inexhaustible, and hence every means of increasing the nitrates in the soil is of the first importance. A promising method is to convert atmospheric nitrogen into nitric acid by electricity; electric storms do this in trivial quantities, as detectible in rain-water, but the marvelous recent growth of electrical invention now accomplishes it by dynamos.

In the development of agricultural colleges and experiment stations chemistry has always been the leading science: of the present directors of United States stations 21 were professional chemists when appointed; in Europe the proportion is even greater.

In the valuable feature of scientific bulletins from the experiment stations, Prof. F. H. Storer of Bussey Institute led the way. But perhaps the most successful popularizer of the science since Liebig was Samuel William Johnson, appointed agricultural and analytical chemist at Yale in 1857, whose books, ‹How Plants Grow› and ‹How Plants Feed,› have been more universally read in this country than any other agricultural works. Another powerful early worker was E. W. Hilgard of the University of California, whose work on soils is a classic. At Cornell, from its opening to the present, George C. Caldwell has held the chair of agricultural chemistry with distinction. Others of note are C. A. Goessmann of the Massachusetts Agricultural College, and the late R. C. Kedzie of the University of Michigan. These pioneers are worthy of remembrance for laying broad and deep the foundations of future agricultural progress.

The Association of Official Agricultural Chemists is by act of 1902 the adviser of the secretary of agriculture in fixing United States food standards.

This science has been important in developing the great manufacturing industries dependent on agricultural products, as of cane and beet sugar, starch, beer, wine, and distilled liquors. The fertilizer industry, opening up vast new stores of plant food,— as the vast phosphate deposits of the United States, the deposits of Stassfurt, Germany, and the nitrate beds of Chile,— is wholly created by agricultural chemistry. It also labors to increase the value of crops for given purposes without increasing their draft on the soil by studying the environing conditions which modify its chemical composition, and investigates the nutritive value of the plant foods so as to produce the most economical results from the raw material. It teaches the best methods of utilizing such foods and of conserving them for the future, develops new staple crops, and opens up new avenues of prosperity.

E. B. VOORHEES,
Director New Jersey Agricultural Experiment Station.

Agricultural Colleges. As a result of national and State co-operation, which enables the ordinary farmer to profit from the experiments of widely separated individuals interested in scientific farming, the United States stands foremost in the matter of agricultural development. Our Department of Agriculture renders the greatest service imaginable to the country; but its facilities are greatly improved by the co-operation of the different State agricultural institutions, while the farmers of each section can rely upon their special State colleges to supplement the work of the national institution.

The Massachusetts Agricultural College is one of the foremost representatives of the typical institution devoted to practical agricultural education, and its work and studies are devoted chiefly to the training of students in modern scientific farming. The work is conducted both in the class-room and on an experimental farm. The institution is located on a farm of 400 acres at Amherst, and its buildings and land are valued at $315,000. Its annual income from the State and United States amounts to $45,000, and it is provided with a permanent endowment fund of over $350,000. There are buildings for nearly every imaginable specialty pertaining to agriculture — a chemical laboratory, botanical laboratory, plant-house, creamery and dairy laboratory, veterinary buildings, barns, museum, library, and entomological laboratory and insectary.

Instruction is given by a corps of 18 professors and assistants in chemistry, botany, agriculture, horticulture, zoology, veterinary science, mathematics, civil engineering, and similar studies. Practical work on the farm is a part of the course, and the students cultivate the whole farm, experimental orchard, and nursery. There are 100 acres devoted to orchards, vineyards, and the cultivation of small fruits; 150 acres under cultivation with field crops, and nearly as many more allotted to grass and hay for the 100 head of cattle which are kept on the farm. Considerably over 1,000 men have been educated at the Massachusetts Agricultural College. A recent census of them showed that nearly 400 are

to-day engaged in agricultural pursuits; more than a score are instructors in other similar institutions; and others have drifted into a variety of callings. The effect of the college on the agriculture of the country must prove of immeasurable value if a similar proportion of its graduates adopt farming for their life's work, and perform their labors in a scientific manner, as they were taught to do at the institution.

The State agricultural and mechanical colleges which have sprung up in most of the leading agricultural States of the East and West, and in many parts of the South, in recent years, have in view the training of young men for scientific and practical agriculture, and also for mechanical and manufacturing arts and sciences. They are endowed by the State, and also by private individuals. They are for the most part under the control of the State Board of Agriculture, the governor, and other State officers; but the president and faculty of each institution practically have all the liberty they demand in carrying out the work according to well-defined policies. Some of these State agricultural colleges are remarkably well equipped and endowed for the work they have in hand. Thus, the Iowa State College of Agriculture has 15 buildings, which have been erected by the State at a total cost of $500,000. There are nearly 1,000 acres of land attached to the institution. A corps of 55 professors and nearly 600 students is engaged in study and work. All kinds of crops raised in Iowa are cultivated on the farm, and cattle, horses, and poultry are kept by the students. Experiments are constantly being carried on by the professors and students in agriculture, horticulture, chemistry, and general farming, and the results of these experiments are published in bulletins and papers for the benefit of the world.

The Pennsylvania State college, called the Agricultural College of Pennsylvania, is even broader in its educational aims than the Iowa college. Almost all studies from agriculture, chemistry, physics, engineering, mining, and mathematics up to philosophy, general literature, and languages are taught there. In recent years this college has steadily broadened as a high-grade technical, scientific, and classical institution. Nevertheless agriculture, in all its wide fields of application, is one of the chief studies emphasized at the college. A correspondence course has in late years been organized for the purpose of instructing students on farms who cannot attend the college, but who wish to avail themselves of the researches and facts obtained at it. Forestry is one of the most useful branches of work carried on at this college; and it not only trains young men to appreciate the value of cultivating orchards and woods, but also turns out practical foresters, capable of taking charge of large forests and converting them into profitable possessions, without destroying and denuding them of trees.

The Michigan State Agricultural College is another institution which, for more than 40 years, has endeavored to help the farmers in their struggle to wrest from the soil a fair compensation for their labors. The original idea of this college was to perfect in their studies all graduates of the common schools who wished to possess a complete practical and theoretic knowledge of the arts and sciences which bore directly upon agricultural and kindred pursuits. Economic zoology, meteorology, physics, veterinary science, entomology, bacteriology, chemistry, geology, and agriculture and horticulture are a few of the studies pursued. Post-graduates can pursue advanced studies in the sciences, and in the library of 20,000 volumes they can find nearly all the literature of value pertaining to their particular studies. There are some 676 acres of land attached to the college, 230 acres of which are devoted to field crops, 45 to woodland, 114 to orchards and garden, 47 to experimental fields, and 240 to forest. There is a fine arboretum, a botanic garden, a grass-garden, and a weed-garden, where 100 or more noxious weeds are grown to show their destructive possibilities to the students. There are some 450 students at the college, and more than half of them take the full agricultural course.

The South has a good institution of this class in the Mississippi Agricultural and Mechanical College, with a faculty of some 24 members, and a student membership of nearly 400. The college is under the management of a board of trustees, with the governor of the State an *ex officio* member. The students who attend this college are paid eight cents per hour for their work in the fields or orchards, which enables them to pay for a part of their living while studying.

The Kansas State College, with its 300 acres of land, buildings valued at $350,000, and a faculty of 45 professors and assistants, has become an important factor in the middle West in developing the agricultural possibilities. Agriculture, engineering, and general and household economics are taught to the students. There is a dairy, blacksmith-shop, foundry, machine-shop, printing-office, and woodwork and painting shop connected with the college, where practical work can be followed by the students.

With agriculture as our leading industry, many of the large universities have in recent years established an agricultural course and experimental farms for work in the regular college course. When this subject is mentioned, one turns instinctively toward Cornell University, with its admirable agricultural and forestry departments; toward the Ohio State University, with its buildings and equipments aggregating nearly $3,000,000 and with an income of $350,000; or toward the University of Wisconsin, or the University of California. These typical universities, which have given agriculture and horticulture a prominent place in their curriculums, send forth annually hundreds of students to teach practical farming to new communities which may still labor under the disadvantage of old methods and ideas of agricultural production. The Ohio State University at Columbus has over 1,000 students, and a corps of 78 professors and assistants; but it aims to give a scientific and classical education to both young men and women. It is divided into six colleges, with one devoted to agriculture and domestic science, and another to veterinary science. Students pursuing other studies can take courses in these departments, and there are also opportunities for graduate studies in the science of agriculture. There is a well-stocked farm of 200 acres connected with the university, a dairy department, a large laboratory for student work

in soils and crops, and a veterinary laboratory and operating building.

In the University of Wisconsin, with its membership rapidly approaching 2,000, and a corps of over 130 professors and assistants, there is a college of agriculture, which gives excellent courses in dairying, veterinary science, experimental farm work, entomology, scientific plant investigation, and general horticulture and agriculture. There are cheese factories, creameries, and dairies on the farm, with large greenhouses for raising plants, extensive barns for cattle, and bacteriological laboratories. The college co-operates with the 60 or more State institutes of the farmers in supplying literature and lecturers, and thus becomes an essential part of the State's chief industry.

Like the two former, the agricultural college of Cornell University, in New York, has become one of the greatest factors in stimulating and broadening the farming interests of the State and indirectly of the whole country, while it has contributed largely to the establishment of agriculture on a firmer and higher scientific basis than ever before in its history.

Agricultural Education. The earliest farmers in America had to contend with innumerable and great obstacles; with the wildness of nature, the attacks of Indians and wild beasts upon their stock, the difficulty of obtaining farming implements and seeds, and with conditions of climate and soil, very different from those of the old countries whence they derived all their methods. The colonial farmer was compelled to use the crudest methods. He cut down, heaped and burned the small trees and undergrowth, and belted the large ones. He scratched the surface a little with a home-made plow, and cultivated his corn and tobacco with a wooden hoe. He harvested the crop that nature gave him in a careless manner and used it wastefully. He cultivated the same field until it was worn out, when he cleared another and moved his family near to it. So long as land was so abundant, no attention was paid to the conservation of fertility of the soil. America was such a vast and fertile country that it took the people over a century to find out that there was any limit to its productiveness. These conditions were quite sufficient to explain the slow progress made in agriculture during the 1st century or more after the settlement of America.

It was not until the close of the 18th century that the attention of practical men commenced to be directed to the discoveries of science, and hopes were excited that immediate benefits would accrue from them to agriculture as they had to the other arts. Lavoisier's discoveries and teachings had aroused the hope that chemistry could do a great deal to promote the advancement of farming. Americans commenced to appreciate their disadvantages as compared with British and continental farmers, and to seek better implements and methods for their work. The newly awakened interest in agriculture was marked first by the formation of agricultural societies. George Washington was one of the best technically educated men in America in his day, and was especially interested in everything pertaining to agriculture. His various State papers show that he not only knew the needs of the country, but that he fully realized that schools for the education of the people and societies for the distribution of knowledge were necessary for the safety of the republic. A few extracts will recall his strong opinions on this subject. In his first annual message to Congress (8 Jan. 1790) he expressed the hope that the "advancement of agriculture, commerce, and manufactures, by all proper means, will not, I trust, need recommendation." and adds, "Nor am I less persuaded that you will agree with me in the opinion that there is nothing which can better deserve your patronage than the promotion of science and literature. . . . Whether this desirable object will be best promoted by affording aids to seminaries already established, or by the institution of a national university, or by any other expedients, will be well worthy of a place in the deliberations of the legislature." Notice how agriculture and a national university for the promotion of science and arts were always associated in Washington's mind. He mentions the advancement of agriculture and the establishment of a national university in the same connection in his first message. He discusses them together in many of his writings during eight years, and finally in his eighth annual message, he says, "It will not be doubted that with reference either to individual or national welfare agriculture is of primary importance. In proportion as nations advance in population and other circumstances of maturity, this truth becomes more apparent, and renders the cultivation of the soil more and more an object of public patronage. Institutions for promoting it grow up, supported by the public purse; and to what object can it be dedicated with greater propriety? . . . I have heretofore proposed to the consideration of Congress the expediency of establishing a national university and also a military academy. The desirableness of both these institutions has so constantly increased with every new view I have taken of the subject that I cannot omit the opportunity of once for all calling your attention to them." With marvelous foresight Washington urged the necessity for scientific research and education in America, and he planned at the same time for institutions to discover and collect knowledge, and societies to disseminate it. He saw also that agriculture was to be the chief industry in the country, and that it would need the assistance of science. Thus he appears to have associated plans for the advancement of agriculture with those for a national university. Congress promptly established the military academy, and some years later the naval academy and the department of agriculture. But it has not yet established the national university, which was the chief agency in Washington's mind for the development of all the sciences and arts of peace.

Agricultural Societies and Fairs.— The first society for the promotion of agriculture in the United States was organized at Philadelphia on 1 March 1785; and on the 4th of July following George Washington and Benjamin Franklin were elected members. A similar society was incorporated in South Carolina in the same year, which proposed, among other things, to establish an experimental farm — the first suggestion of the kind in our history. The New York society for the promotion of agriculture, arts, and manufactures, which had been organized on 26 Feb. 1791, published its first small volume of transactions in 1792. The Massachusetts So-

ciety for the Promotion of Agriculture was established 7 March 1792, and commenced, in 1797, the publication of bulletins. The Society for Promoting Agriculture in the State of Connecticut was organized in 1794, and published its first volume of proceedings in 1802. Washington was evidently familiar with the work of these agricultural societies; but his knowledge of such agencies was not limited to his own country. In Great Britain, the Bath and the West of England Agricultural societies had been established. Sir John Sinclair, the "inventor of statistics" and president of the Highland Society, had established, in 1791, the British Wool Society and the Sheep Fair at Newhalls Inn. After agitating the subject for a number of years, Sinclair secured the establishment of the Royal Board of Agriculture, and was appointed its first president in 1793. Washington's correspondence with Sir John Sinclair shows that he had the benefit of all the information to be obtained from the father of the British board of agriculture. Agricultural societies naturally led to the establishment of fairs and exhibitions. A member of the Massachusetts Society suggested first in 1801 that agricultural fairs should be held regularly at Cambridge spring and fall, and premiums be given for farm products. No action appears, however, to have been taken with regard to this suggestion. Dr. Thornton, the first commissioner of patents at Washington, suggested in 1804 that the sale of agricultural products and of cattle would be promoted by the holding of fairs on market days, as in England. As a result of this suggestion we learn from the 'National Intelligencer' of that year that fairs were held "in the mall on the south side of the Tiber." The first fair proved such a success that the citizens raised an appropriation of $50 for premiums for the next one, which was held in April 1805. The third fair, held in November 1805, appears to have been the last. Gov. Edward Winslow, of Massachusetts, is said to have brought to Plymouth, in the ship Charity, in 1694, "the first neat cattle that came into New England." It was appropriate that his descendant, Elkanah Watson, of Plymouth, should import the first pair of Spanish Merino sheep into Massachusetts, and should then give notice of an exhibition of them at Pittsfield. This small exhibit led to a larger enterprise and the establishment of stock shows in America. An invitation was published by Watson and some 20 other persons calling an exhibition of stock at the same place on 1 October. This cattle show was so successful that it became a permanent institution in Massachusetts. A number of public-spirited citizens of Maryland, Virginia, and the District of Columbia had in the meantime formed, in 1809, the Columbian Agricultural Society, which was for many years actively engaged in the work of educating the farmer through the agency of fairs. From these beginnings agricultural societies have spread all over our country, and agricultural fairs have become a potent agency for the dissemination of valuable information with regard to new crops, implements, stock, and improvement in agriculture generally. Nearly all of the States have now either boards of agriculture or commissioners or secretaries of agriculture in charge of the farming interests. Their work varies, but usually includes the collection of agricultural statistics, the preparation of weather and crop reports and the oversight of the stock interests, and frequently also the inspection and analysis of fertilizers and mixed cattle feeds, the testing and examination of dairy and other food products. Some of the State boards conduct the agricultural colleges, hold fairs, give premiums for fine stock, and hold farmers' institutes. The boards, commissioners, and societies all publish reports and bulletins and many of them accomplish a great deal of admirable educational work. The Patrons of Husbandry (Grange) and National Farmers' Alliance, organizations with many subordinate branches and local societies, have exerted great influence especially in educating the farmers and their families. The Farmers' National Congress meets once a year for the discussion of questions of general interest. For the stock interests, we have in this country a national live stock association, 5 national dairy unions, and 56 State dairy associations. There are 14 cattle breeders associations representing the interests of as many different important breeds, 18 horse breeders associations, 29 sheep breeders associations, 17 associations of swine breeders, etc. Nearly all of the States protect their stock from diseases through the agency of sanitary boards or veterinarians under the direction of the State boards or commissioners. There is a national league for good roads that is doing much to educate public opinion. Ten States have forestry commissions or provide for forest protection and improvement in some way. There are besides 18 forestry associations which are doing much educational work. Eleven national or interstate, and 54 State horticultural and kindred societies are at work. (For the names of these societies and the addresses of their officers, see the Year-book of the United States Department of Agriculture for 1898.)

Agricultural Schools.— The origin and development of agricultural schools in America was a part of a general educational movement against the old classical college and in favor of scientific and technical education. Perhaps the demand for agricultural education was the first one to be heard; but it had its origin in the same causes which gave rise to the demand for the application of science to all the arts and professions in life.

As the great universities of Europe grew out of monastic and cathedral schools, so our first American colleges were all the children of the churches. The preachers were in the early days almost the only learned men, and therefore the only teachers. In the case of the rural schools the preacher was both school director and teacher. The institutions for higher education were also founded and controlled by the associations and presbyteries of the different denominations, and the most learned of their clergy became the instructors. Naturally enough, as their founders and teachers were all preachers, these early colleges were devoted almost exclusively to the cultivation of theology, classics, and philosophy. Their parson-teachers taught what they held to be the only thing worth learning, and they were right in putting character and culture above everything else. Their methods produced a race of preachers, teachers, lawyers, statesmen, and soldiers scarcely equaled and never surpassed in any country. But a new and rapidly growing country like America needed engineers, chem-

ists, miners, and manufacturers, and an ambitious and intelligent people were not slow to make their wants heard. Some of the physical sciences, notably chemistry and geology, had already made great progress, and had revolutionized some of the arts. The popular writings of great scientific men, notably Liebig's 'Letters' on chemistry, were eagerly read, and people everywhere cherished bright hopes of the benefits to be derived from the application of science to the industries of life, and especially to agriculture. Discovery and invention were already doing much to develop the material resources of the world and to change the occupations of men. Steam was beginning to be used for the purpose of transportation, chemistry was being applied in working iron, in dyeing fabrics, and in many other arts. Great railroads were to be built, but with the exception of the military academy at West Point, there was no school to train the engineers to survey them. Mines of coal and iron were to be opened, but miners had to be imported to open them. Factories needed to be built, but engineers had to be brought over from England or Holland to build them. Iron works and many other important industries were calling loudly for chemists, who had to be obtained from Germany or France. These influences, but more especially the need of scientific knowledge in a rapidly developing country, produced a profound effect on the theories and practice of education; and thus a vigorous demand arose for the sciences and their applications to the arts of life. The old college was not meeting the new demands; but what the new college was to be, and what its methods, no one knew for a long time.

Columbia College, in the city of New York, appointed, in 1792, Samuel L. Mitchell "professor of natural history, chemistry, and agriculture." The records of the college do not show what instruction he gave in agricultural science, if any, but Prof. Mitchell, so far as we know, was, by title at least, the first professor of agriculture in America. The Philadelphia Society for the Promotion of Agriculture, of which Washington was an honorary member, appointed a committee on 21 Jan. 1794 to "prepare a plan for establishing the State Society for the Promotion of Agriculture, connecting with it the education of youth in the knowledge of that most important art." This committee made a report offering several alternative propositions for promoting agricultural education. One suggestion made was "the endowment of professorships to be annexed to the University of Pennsylvania and the College of Carlisle, and other seminaries of learning, for the purpose of teaching the chemical, philosophical, and elementary arts of the theory of agriculture." Another suggestion was to use the common school system of the State to educate the farmer in his business, "the county schoolmasters being made secretaries of the county societies, and the school-houses the places of meeting and the repositories of their transactions, models, etc. The legislature may enjoin on these schoolmasters the combination of the subject of agriculture with other parts of education." This is, so far as we know, the first formal effort made in the United States to present the claims of agricultural education to a legislature and to incorporate instruction in agriculture in the common schools.

United States Department of Agriculture.— The war with England, the expansion of territory, the rapid development of manufacturing, and many other causes, contributed to retard the progress of agricultural education for several decades after the beginning of the century. The agitation continued, but little was accomplished until after 1840.

Upon the motion of Elkanah Watson, the Berkshire Agricultural Society of Massachusetts presented in 1817 a memorial to Congress praying for "the establishment of a national board of agriculture in accordance with the original suggestion of President Washington." The bill reported in the House of Representatives was promptly defeated by a large vote. It was well known that President Madison was opposed to it on constitutional grounds. Others based their opposition on the indifference of the farmers of the country and the idea that such a board was not needed. The only striking event in the agricultural history of the country during the next decade was the agitation of silk culture, commonly called the "Morus multicaulis" craze from the variety of the mulberry tree which was introduced everywhere to supply food for the silk worm. Congress responded to the popular demand for information on this subject by ordering the preparation and publication of a manual of silk culture, which was done.

The United States Department of Agriculture grew finally out of the recommendation of President Washington for a national board of agriculture, but more immediately out of the seed distribution originated in the Department of State during the presidency of John Quincy Adams. The patent office was first in the hands of the Department of State, and the seeds collected by consuls in various parts of the world were turned over to it, as the scientific branch of the government for distribution. So it came about that when on 4 July 1836, the patent office was made a separate bureau and Henry L. Ellsworth, a practical farmer of Connecticut, was appointed commissioner, he found it one of his duties to distribute seeds and plants. It was a congenial duty and one for which he was well qualified both by education and experience. During his travels over the country as Indian commissioner, Mr. Ellsworth had been deeply impressed with the agricultural possibilities of the western prairies and also with the great ignorance and destitution of the settlers upon them. He believed that what they needed was better implements and seeds adapted to the climate and soils. So deeply impressed was he with the necessities of these people that, without the authority of Congress and outside of business hours, he collected seeds and plants, which he distributed to farmers in all sections of the country, but especially to those in the far West, using the postal franks of members of Congress for this purpose. This was the beginning of the seed distribution by the United States government, which has since grown to such colossal proportions. Thus also was born the United States Department of Agriculture. In his first annual report Mr. Ellsworth begged earnestly for an appropriation to continue and enlarge this distribution of seeds and one was made during the last days of the Twenty-fifth Congress which provided $1,000 from the patent office fund "for the purpose of collecting and distributing seeds, prosecuting agricultural in-

vestigations, and procuring agricultural statistics." With the exception of the years 1840, 1841, and 1846 Congress made a small appropriation for this purpose each year from the patent office fund. The first separate appropriation for agriculture, made in the year 1854, was $35,000, and it has never been less than that sum. An agent was authorized also at this time to "investigate and report upon the habits of insects, injurious and beneficial to vegetation," and a botanical garden was established. The same year arrangements were made with the Smithsonian Institution for collecting meteorological statistics. The present United States Department of Agriculture was established by an act of Congress, approved by President Lincoln on 15 May 1862. This act was chiefly due to the strong plea made by Commissioner of Patents David P. Holloway, of Indiana. It is remarkable that the other great act for the promotion of agriculture in America, known as the land-grant act establishing colleges of agriculture and mechanic arts, was passed by the same Congress and approved by President Lincoln on 2 July of the same year, both in the midst of the terrors of the Civil War. The act of 15 May 1862 did not establish an independent department of the government. Its chief officer was styled simply "commissioner of agriculture." He did not become a member of the Cabinet until 11 Feb. 1889, when President Cleveland approved another act of Congress making the Department of Agriculture an executive department.

Agricultural Colleges.— The demand for scientific and technical education did not cease as the years passed by, but grew louder and louder with the development of the country. The history of the agitation in New York may be taken as an illustration. In 1819 there was published anonymously at Albany a pamphlet on "the necessity of establishing an agricultural college," which has been commonly attributed to that active and intelligent man, Simeon De Witt, Surveyor-general of New York. He proposed the establishment of an institution to be called the agricultural college of the State of New York, to be endowed by the State and conducted under State authority. The 'Transactions' of the New York Agricultural Society for 1822 contain allusions to the same subjects, and the matter was never allowed to drop entirely out of sight. About 1825 a private agricultural college or school was undertaken in Columbia County. This was the period (1830 to 1850) of the agitation for the so-called "manual labor schools," and many of the schools of the time took that form. The Oneida Institute was one of the first of these schools, and it is said to have had a course of instruction in practical agriculture. These were not manual training schools or technical schools in the modern sense, but schools having farms attached where the students could support themselves by manual labor while pursuing their studies. This plan, which was received with much popular favor for a time and led to the establishment of numerous schools, was soon found to be impracticable and abandoned. The demand in New York for agricultural education grew steadily, and by 1838 petitions bearing 6,000 signatures were presented to the legislature demanding State aid in behalf of agricultural schools. The committee to whom the petitions were referred deplored in strong language "that there is no school, no seminary, no department of any school in which the science of agriculture is taught," and recommended very strongly the establishment of a school of agriculture. No action was taken at this time, but the matter came up in a different form at each succeeding session of the legislature, and appears to have grown steadily in favor. The State Agricultural Society helped greatly to advance the interests of the cause, and in 1844 appointed a committee of which Gov. Seward, Lieut.-Gov. Dickinson, and James S. Wadsworth, were members, to promote "the introduction of agricultural studies in the schools of the State," and also "for the purpose of selecting books for family and school libraries." It was resolved at the same time, "That this society regards the establishment of an agricultural institute and pattern farm in this State, where shall be taught thoroughly and alike the science, the practice, and the profits of good husbandry, as an object of great importance." This committee co-operated with the association of school superintendents, with the result that that body adopted, in June 1844, a resolution drawn by Prof. Potter, of Union College, setting forth the opinion that "the time has arrived when the elements and scientific principles of agriculture should be taught in all schools." Still the State took no action. However, numerous private agricultural schools were established.

Gov. Hamilton Fish first recommended, in January 1849, in his annual message to the legislature, the establishment of a State agricultural college. During the following session of the legislature Prof. Johnson, the great agricultural chemist of Scotland, was invited to Albany and delivered a course of lectures under the auspices of the New York Agricultural Society. The same year this society established a chemical laboratory at Albany for the analysis of manures, fertilizers, etc. Still nothing was done about the school. Prof. William H. Brewer writes: "In 1850 Mr. John Delafield, a graduate of Columbia College, where he may have received instruction from Prof. Mitchell, was living on one of the best farms of the State, in the town of Fayette, Seneca County. He was at one time president of the New York State Agricultural Society, and originated and carried out an agricultural survey of Seneca County. He took a deep interest in the cause of agricultural education, and owing to his action and energy on 15 April 1853, the State passed an act establishing an agricultural college. This act created a board of 10 trustees, of which Mr. Delafield was president, but appropriated no money. The college was to be located on Mr. Delafield's farm in the town of Fayette, but as he died 22 October of the same year nothing more was done about building a college there." The Rev. Amos Brown, principal of Ovid Academy, who was to become later the chief assistant of Senator Morrill in securing the passage of the land-grant act establishing agricultural colleges, appears to have gotten his inspiration and information from Mr. Delafield. He afterward became president of the People's College near Havana, N. Y., and after the passage of the Morrill Act in 1862 secured an act from the legislature of New York, giving the whole of its share of the land-grant to this college. But that institution failed to comply with the condi-

tions of the law, and the land-grant of the State of New York was turned over to Cornell University, which thus became the agricultural college of the State. This narrative has been introduced to show the growth of the idea which led to the establishment of Cornell University, probably our greatest agricultural institution. See CORNELL UNIVERSITY.

The first agricultural college to be actually established and put in operation was that of the State of Michigan. Article 13, section 11 of the constitution of the State of Michigan adopted in 1850, says: "The legislature shall encourage the promotion of intellectual, scientific, and agricultural improvement; and shall as soon as practicable, provide for the establishment of an agricultural school." This was the first State constitution to provide for the establishment of an agricultural school. It is noteworthy, also, that it was the first one to provide that all instruction in the district schools should be conducted in the English language. The act establishing the State Agricultural College of Michigan was passed on 12 Feb. 1855. The college was located upon a farm of some 500 acres, situated about four miles east of the city of Lansing; buildings were erected, and the college was formally opened in May 1847.

The legislature of Maryland incorporated the next agricultural college in 1856, which was, however, in part a private institution. Some 500 citizens of Maryland, and of the District of Columbia, together with a few from adjacent States, subscribed to a certain amount of stock, which the legislature required should be provided. The stockholders elected a board of trustees, and this body located the college upon the estate of Charles B. Calvert, situated in Prince George County, about nine miles east of the city of Washington. The institution was opened for students in September 1859, when Prof. Joseph Henry of the Smithsonian Institution, delivered the oration.

Marshall P. Wilder first urged the importance of establishing an agricultural college in Massachusetts, in an address before the Norfolk Agricultural Society made in 1849. The State Senate of Massachusetts passed a bill in 1850 establishing such a school, but it failed in the House. A committee was appointed to investigate the matter, and they sent Prof. Hitchcock to the continent of Europe to visit agricultural schools. His report was transmitted to the legislature by the governor in the following year, with the result that the Massachusetts Board of Agriculture was established in 1852. Mr. Wilder kept up the agitation, however, and finally in 1856 succeeded in obtaining from the legislature a charter of the Massachusetts School of Agriculture. The Massachusetts Agricultural College was not regularly opened, however, until 1867. The general assembly of the State of Pennsylvania incorporated the Farmers' High School, now the State College, in 1854. The act provided that people of different sections of the State might offer land and property and thereby secure its location in their midst. Funds for building and equipment were provided from the State treasury. The State Agricultural Society made certain donations, and the college was opened for students in the winter of 1859. These were the leading agricultural schools established before the passage of the Land-grant Act in 1862.

Closely related to these agricultural schools were the scientific schools established at Yale and Harvard between 1840 and 1850, in response to the same demand for a new education. John P. Norton was appointed professor of agricultural chemistry, vegetable and animal physiology at Yale College, New Haven, Conn., in 1846. Thus was begun the Sheffield Scientific School, which was more of an agricultural institution than any of the other schools of that time. Prof. Norton began his lectures in 1847, and for some years wrote voluminously for agricultural journals. He also prepared and published his first work, 'The Elements of Agriculture.' Among his first students in the course in agricultural chemistry was the distinguished Prof. W. H. Brewer, of the Sheffield Scientific School at Yale. The Lawrence Scientific School at Harvard, established about the same time, was founded upon an endowment of $40,000, given by the Lawrences, who, being interested in factories, caused this school to direct its attention more to the applications of chemistry to manfactures. Francis Wayland, president of Brown University, became greatly interested at this time in scientific and technical education, and took a prominent part in the discussion of the reforms needed to adapt the institutions of America to the requirements of the time. In his little book on the 'Present Collegiate System of the United States,' he argued earnestly in favor of the introduction of scientific subjects into the college curriculum and the adoption of a system of electives. A science hall and a museum of geology were erected at Brown in 1840; but means failed to support the scientific work, and Dr. Wayland was constrained to resign in 1855, when the old classical course was re-established. These changes were all parts of a general movement for the modification of the classical curriculum, and the introduction of scientific and technical study. Wherever this was done the sciences pertaining to agriculture were sure to be introduced. The next great movement in agricultural education began with the Land-grant Colleges. See COLLEGES, LAND-GRANT.

Requirements for Admission.— The requirements for admission to the agricultural colleges vary in the different States in accordance with the school systems and the other opportunities for preparation. The Western and Southern agricultural colleges usually take the students from what is known in this country as the eighth or ninth grade of the public school course. A majority of the institutions require for admission either certificates from the preparatory schools or examinations in the more important subjects. The average standard of admission to the agricultural colleges is presented in the report of the Committee on Entrance Requirements made to the association of colleges at the meeting in November 1896. They recommended the following (Rep. of Bureau of Education, 1896–7, p. 429):

"The committee holds that it is advisable, as a beginning, to determine the requirements in a few subjects upon which it is possible for all the colleges to agree, and to recommend others, which although too high at present for adoption by some of these institutions, may yet serve as a standard or goal toward which effort may be directed.

"As a standard series of entrance requirements, to be adopted as soon as possible, we recommend the following: (1) Physical geography; (2) United States history; (3) arithmetic, including the metric system; (4) algebra to quadratics; (5) English grammar and composition, together with English requirements of the New England Association; (6) plane geometry; (7) one foreign language; (8) one of the natural sciences; (9) ancient, general, or English history."

Many of the universities have a much higher standard of admission, some of them requiring a preparation fairly comparable with that for students entering the literary and scientific courses. Candidates for admission at Cornell, for example, must be at least 16 years of age and pass an examination in English, geography, physiology, and hygiene, history of the United States and England, Greece or Rome, plane geometry, elementary algebra, and at least two of the following subjects: Greek, Latin, French, German, and advanced mathematics.

Courses of Study.— The courses of study in the separate colleges for agriculture and mechanic arts are not essentially different from those of the agricultural departments of the State universities, with the exception that in most cases the work of the separate colleges begins a little earlier and is not so much differentiated as that in the universities. Many of the separate agricultural colleges have, however, quite as high requirements for admission as any of the State universities, and do as high a grade of work as the best of them. On the whole, it appears that practical agriculture occupies the highest place in the separate colleges, though more research in the sciences pertaining to agriculture is being carried on in the universities. In universities in which departments of agriculture are maintained, it may be said in general that the tendency is to make the four years' course in agriculture correspond in scope and thoroughness with those in philosophy, sciences, and engineering. As more means are obtained, instruction in agriculture is divided among an increasing number of specialists, who are provided with separate buildings, laboratories, and shops. It is characteristic of American State universities that they are seeing more clearly that agriculture and manufacturing are important human interests which may rightfully claim the best efforts of the greatest scientific intellects for their advancement, and that on the basis of agricultural sciences may be built a system of instruction in literature, mathematics, and technology which is as well or better adapted to produce scholars, investigators, and leaders in civilization as was the old philosophical or the pure science course. The courses of study in agriculture are variously arranged. Nearly all these institutions maintain a four years' course, which is made up usually of two years of preparatory sciences and general culture studies, followed by two years of more advanced scientific and technical agricultural work, largely elective. At present there is little demand in our country for the all-around agricultural expert, and few colleges attempt to educate them. Such an expert cannot be trained in four years, if at all. At present the agricultural colleges content themselves with giving their students a fair general knowledge of the sciences underlying agriculture, horticulture, and the animal industry, with opportunities to acquire experience in some one line of practical work. The arrangement of this four years' course differs a good deal in different institutions, but the standard for it is laid in the reports adopted by the association of American agricultural colleges at its meetings in 1896–7.

The course of study presents the largest problem now before the faculties of our colleges. The present courses and methods have been criticised for their lack of "pedagogical form," for the "confusion of studies," and especially for lack of "orderly sequence in the progress of instruction" which has made the classical education and to a certain degree the scientific and engineering courses of our institutes of technology processes commanding the respect of scholars the world over. These critics are in error when they speak of agriculture as an independent science, and propose to formulate the instruction in it as they would that in chemistry or in biology. The fact is, agriculture is not a science but an art, and what we are attempting to do in these colleges is to carry out the injunction of the Act of Congress of 1862 and "teach the sciences (chemistry, physics, geology, biology, vegetable physiology, etc., each including numerous branches), related thereto." For this reason the course of study in agriculture with good "pedagogical form" must be made up of a course in chemistry and agricultural chemistry, a course in vegetable physiology, a course in the physiology of animals, a course in soil physics, etc.— many distinct courses. When the student has mastered all these it would seem to be possible, if he stays at the college long enough, to teach him in good "pedagogical form," some of their applications in agriculture. As Prof. Jordan, director of the Maine agricultural experiment station, has well said: "The real and important need of which the farmer is conscious is for a knowledge of conditions and not for methods or for skill in manipulation. When he clearly understands the reasons for that which goes on about him, the right method will appear. The difficulties lie with explanations, not with mechanical processes. And besides, agriculture is not a business involving such delicate and intricate mechanical operations that attendance upon a college would be justified in order to learn them, although the modern dairy, the forcing house, and the fruit garden do require skill. The spraying of fruit with fungicides and insecticides illustrates how readily the necessary manipulation was acquired when the reasons for these operations became evident. It is the explanation of phenomena, then, which the extended course of study should give in order that the farmer may know how to adapt himself to the varying and complex conditions which he meets in his work."

This is the real problem and one which the colleges and universities are working out with marked success. Perhaps the colleges and universities having departments of agriculture are doing more immediate good to the largest number of persons through their short courses and their special schools for dairying, horticulture, etc., than through the long course. These short courses are designed to meet the wants of young farmers who desire practical, helpful instruction in agriculture after leaving the high schools and before taking up their chosen vocations.

A number of the colleges maintain courses in agriculture of 12 weeks beginning the first of January of each year. They usually include lectures on feeds and feeding, breeds of live stock, elementary agricultural chemistry, physics of soils, meteorology, elements of vegetable physiology, the chief facts of veterinary science, dairying, horticulture, and some of the leading facts of bacteriology. Courses are selected from these to meet the needs of special classes of students from different districts. Laboratory practice is usually given in soil physics, stock judging, dairying, vegetable physiology, and practical horticulture. Other short courses are limited to the chemistry and bacteriology of milk and practical dairying, or to plant propagation, grafting, pruning, and practical horticulture. These courses are more largely attended than the four years' course. The tendency at present seems to be to split up the four years' course into special courses or to distribute among the different short courses students who cannot attend the institution more than a few months at a time. It is encouraging to note that such students frequently return winter after winter for additional training.

Expenses of Students.— The expenses of students in the agricultural colleges of the United States vary with the location and advantages offered. The tuition is uniformly free to all students pursuing the agricultural courses. It is customary to charge small fees to cover the actual expenses of material used in the laboratories and shops. Students pay their own board and personal expenses. Some institutions give free lodgings, though a majority charge only the actual cost of the maintenance of the buildings, fuel, lights, etc. Many institutions have special funds with which to pay for student labor, which usually takes the form of a fixed allowance for work regularly performed. The total college expenses of a student will vary from $150 for a session of nine months at a Western or Southern college, located in the country, to $400 or $500 at a university in one of the Eastern States. More assistance and more opportunities for self-support are offered agricultural students than any others in our institutions. The tendency everywhere is to increase these opportunities and to reduce the expense of the students of agriculture, while all the facilities provided them are constantly improved.

Extension Work in Agriculture.— The farmers' institute is to the adult farmer what the agricultural school is to his son. They were the outgrowth in part of the public meetings of agricultural societies and State boards of agriculture, and in part of the extension work of colleges and universities. The object of these institutes is to bring the workers in the agricultural sciences and the practical agriculturists together for the discussion of questions of mutual interest. Through such discussion the farmer gets the benefit of the information which the scientist has obtained in the course of his investigations, and the scientist learns what the farmer's needs and difficulties are. The results of the practical tests made by the farmer of the scientist's theories are also brought out. By such conferences both classes of workers have their opinions and experiences broadened. Institutes in the United States are carried on under all conceivable auspices; most commonly, however, by the State commissioners, the State boards of agriculture, or the agricultural colleges. In some States there is an independent organization with a secretary of institutes in charge. Some States make special appropriations for institutes, others merely allow a limited amount of the funds appropriated for the board of agriculture or college to be used for this purpose. Subjects connected with good roads, public education, and the interests of the home and farm are also discussed frequently. Those connected with sectarian religion or partisan politics should be carefully excluded, but almost any other topic of interest to the local community may properly find its place on the programme of a farmers' institute. In States where institutes have beeen carefully planned and systematically conducted by competent persons they have become exceedingly popular, with the result that large appropriations are being made for them each year. Something like the farmers' institute is now held in almost all the States in the Union.

Closely related to the farmers' institute are the various other methods of agricultural college extension work, such as co-operative field experiments, correspondence courses in agricultural sciences, reading circles for farmers, and itinerant agricultural schools. Co-operative field experiments were inaugurated soon after the establishment of the colleges for agriculture. The college or station makes plans and supplies the fertilizers or gives prescriptions for the same, with full directions as to methods of carrying out the experiments. The farmers report upon blanks prepared for the purpose, and the different results are compared and published. A great deal of good has been accomplished in this way, especially in educating farmers as to the proper method of using chemical manures. Similar methods have been used in testing seeds of field and garden crops, and in testing insecticide and fungicide materials and methods. Such co-operative experiments have done much to promote the study of scientific agriculture in the States, and especially to develop habits of observation among the younger farmers, who are always the ones to take hold of this work.

Instruction by correspondence and by courses of home reading in agriculture have been well developed under the direction of the State College of Pennsylvania. The main features of the plan are, "first, a carefully prepared course of reading designed to cover the most important branches of agricultural science and practice; second, a reduction of the price upon the books needed; third, personal advice and assistance through correspondence; fourth, examinations upon the subjects read, with certificates and diplomas for those attaining a certain grade of excellence." "This course has attracted great attention at home and received numerous applications from farmer students, many of whom have done excellent work, completed the prescribed courses, and received certificates." The courses have now been extended to include five subjects, with five books in each one; namely, crop production, animal production, horticulture, dairying, and domestic economy. A supplemental list of 15 books is suggested from which students may select reading matter to form additional courses if they desire. The full course consists of the thorough study of 10 books, followed by an examination. Lessons are

provided from the various books, and sent the students free of cost, in the form of printed slips. They give suggestions for study, observation, and experiment, with references to the books recommended. Each lesson is accompanied by an examination paper covering the particular subject. The students are expected to file answers to all these questions and discuss them before they receive the second lesson.

The itinerant agricultural school, a still later scheme, has been best developed in the State of New York, under the so-called Nixon Bill, "for the purpose of horticultural experiments, investigation, instruction, and information in New York." This bill placed the sum of $35,000 under the control of the college of agriculture at Cornell University for the two years 1899-1900, and has enabled it to inaugurate a number of most interesting and promising experiments in promotion of agricultural knowledge, especially of nature study in the common schools. The itinerant agricultural school is one only of the plans now being tested by this institution. The meetings of these schools last two or more days.

Agriculture in the Common Schools.— From the earliest time it has been the idea of the friends of agricultural education that instruction in this subject should be given in the common schools. The subject has been presented to the legislatures of many of the States, and by some it has been required to be taught. Any real instruction in agriculture must be based upon a knowledge of chemistry, geology, and the physiology of plants and animals. Such a knowledge cannot be given to young children, and the old-fashioned school teacher, trained to study books, and not things, could give no instruction in nature or science. The whole system of education had to be revolutionized to prepare the way for the study of agriculture in the schools. Since the introduction of the natural method great progress has been made. Agricultural colleges have trained the professors, who, in normal schools have taught the teachers, who in turn have introduced the new methods in the common schools. The following extract relating to the Cornell attempt to introduce nature teaching into the rural schools is from 'Popular Education for the Farmer,' by A. C. True, Ph.D.

There is every reason to believe that the plan of "nature teaching," as proposed by Cornell University, may prove a grand success and be a very great benefit to farmers' children. The element of education which is at present most lacking in our common schools is the training of the powers of observation. The children need above all things else to be taught to observe carefully and correctly and to state their observations in clear terse language. The ordinary child, whether on the farm or in town, actually sees comparatively little in the world about him. The wonders of the trees and plants in park or meadow, of birds and insects flying about the house, float like shadowy visions before his eyes. "Seeing, he sees not." He needs a teacher who can open his eyes and fix his mind on the realities among which his daily life is passed. This accurate observation of natural objects and facts is the only foundation on which scientific attainments can rest. The scientist is chiefly a man who sees better than his fellow men. But it is also a great help in practical life. Many farmers acquire much of this power by their own unaided efforts. And these are the very men who most regret that they did not have in early life the help of a trained teacher. The farmer's child lives where he has the best opportunity for such training. It would benefit him in the practice of his art, and it would add an interest to his life which would do much to wean him from a desire to leave the farm for the turmoil and uncertain struggles of the town. With proper provision for the training of teachers in normal and other schools, it would be entirely feasible to have this nature teaching in all our common schools within a few years. It is such teaching that the child mind craves. With it the school becomes a delightful place and the teacher an angel of light.

Thus far only a few attempts have been made in this country to provide agricultural instruction of the high school grade. It is true that some of the agricultural colleges receive students directly from the common schools, but the constant tendency is to raise the grade of instruction in these institutions to a college basis and, under any conditions, they very imperfectly perform the duties of secondary schools of agriculture. The University of Minnesota has in recent years maintained a school of agriculture in which instruction in agriculture of a lower grade than that given in the college of agriculture has been successfully imparted. This school has proved quite popular. Some 300 students were in attendance last year, and it has been found desirable to offer courses for girls as well as boys. The State of Alabama has recently provided for the maintenance of a school of agriculture of secondary grade in each of the nine congressional districts of the State.

The establishment of such special schools of agriculture of high school grade is greatly to be commended. One of the best effects of such schools at the present time is to show the people what distinctions should be drawn between colleges and high schools for agricultural education. By the separation of these grades of instruction the colleges will be enabled to do their work more efficiently, and better opportunities will be secured for those students whose previous training only fits them for high-school work in agriculture. But it is not believed that these special agricultural high schools will fully meet the needs of our farmers for agricultural instruction of this grade. Any school so distant from the farmer's home as to necessitate long journeys and residence at the school for two or more years must necessarily be too expensive for most of the farmers' children, especially after they have reached an age when their services may be more or less utilized on the farm. What is needed is courses in agriculture in numerous schools to which farmers' children resort, near their homes, to "finish" their education after they are through with the common schools.

Research in the sciences related to agriculture was always prominent in the minds of the advocates of agricultural education. After the agricultural colleges were firmly established, and the work of instruction was well under way, it became evident that the department of research in these institutions needed a special endowment and to be placed under a somewhat separate management. The funds provided were not sufficient for the purposes of instruction, and research and experiment were in danger of being neglected at the colleges so thronged were they with the young people who came to secure the benefits of this free tuition.

Several of the land-grant colleges early attempted to establish separate departments for scientific research and practical experiments on the plan of the German experiment stations. The act establishing the agricultural college of Maryland, passed in 1856, contained a section requiring the college to establish a model farm and conduct "a series of experiments upon the cultivation of cereals and other plants adapted to the latitude and climate of the State of Maryland, and keep a careful record of the kind of soil upon which they were undertaken, the system of cultivation adopted, the state of the atmosphere, and all other particulars which may be necessary to a fair and complete understanding of the results of said experiments." This work was commenced in 1858 and continued two or three years only, when the Civil War stopped all the operations of the college. When Connecticut established her agricultural school in connection with the Sheffield Scientific School of Yale College, Samuel W. Johnson was appointed professor of agricultural chemistry, and experimental work was commenced. "To the influence of

the professors and pupils trained in this school, more than to any other single cause, is due the recognition of the importance of the establishment of agricultural experiment stations." In 1870 the trustees for the Massachusetts society for promoting agriculture granted to Harvard College a sum of money "for the support of a laboratory and for experiments in agricultural chemistry to be conducted upon the Bussey estate." A school of agriculture and horticulture had been founded upon the bequest of Benjamin Bussey. The work of the new institution commenced in 1871. The experiments consisted of field tests of fertilizers and chemical analysis of commercial manures. The first report was published in December 1871. Other interesting and valuable work was done the next few years, but the commercial crisis of 1873 crippled the institution financially, and it has since been able to make comparatively few original investigations.

At a meeting of the State Board of Agriculture of Connecticut on 17 Dec. 1873 Prof. S. W. Johnson of New Haven, and Prof. W. O. Atwater of Wesleyan University, urged the establishment of an agricultural experiment station "after the European pattern." The result of this movement was that the State of Connecticut made, in 1877, an appropriation of $5,000 "to promote agriculture by scientific investigation and experiment." This station was first connected with the chemical laboratory of Wesleyan University, at Middletown, which had been established by Orange Judd and was in charge of Prof. Atwater, but after two years it was reorganized under the direct control of the State and permanently located in the neighborhood of New Haven. The State of North Carolina established an agricultural experiment and fertilizer control station in connection with the State University at Chapel Hill, on 12 March 1877. The Cornell University experiment station was organized by the faculty of that institution in February 1879 without any special appropriation. The New Jersey station was organized in 1880. The Tennessee experiment station in 1882. From these beginnings the experiment stations multiplied in the States until 1887, when Congress passed the Experiment Station Act, known as the "Hatch Act," there were 17 stations already in existence.

The stations were also authorized to publish annual reports of their operations, and "bulletins or reports of progress" at least once in three months, which should be sent to "each newspaper in the State, and such individuals actively engaged in farming as may request the same." The franking privilege was given for station publications. In the annual appropriation bill for the Department of Agriculture for the fiscal year ending 30 June 1889, Congress established the office of experiment stations as a branch of the Department of Agriculture. It compiles and publishes the results of their work, and aids them in many ways.

The work of the American Agricultural Experiment Station supplements that of the colleges in many most important ways. It is fully described in the admirable publications issued by the office of experiment stations of the United States Department of Agriculture, to which the reader is referred for fuller information. See AGRICULTURAL EXPERIMENT STATION.

Consult: 'Reports and Year Book of the United States Department of Agriculture.'

CHARLES W. DABNEY,
President of the University of Cincinnati, Cincinnati, Ohio.

Agricultural Experiment Station. An institution for scientific research in agriculture. The modern agricultural experiment station owes its origin chiefly to the work of Boussingault and Liebig, born respectively in 1802 and 1803, although the earlier work of Sir Humphrey Davy, De Saussure and others had prepared the way for that of these great chemists. During the third decade of the century Boussingault established and for a few years maintained a chemical laboratory on his farm, and there began the combination of field experiment with laboratory investigation which characterizes the experiment station of to-day.

In 1837 a young Englishman, John Bennett Lawes (q.v.), began making experiments in the use of bone superphosphate on his ancestral estate at Rothamsted, near St. Albans, Hertfordshire, about 25 miles northeast from London. The success of these experiments led him to engage in the manufacture of superphosphate and also stimulated a desire for further investigation, and after some years of preliminary work, in 1843 he associated with himself Dr. Joseph Henry Gilbert, a young chemist and a recent pupil of Liebig, and the two entered upon a systematic line of research which has been continued without material change of original plan until the present day. For more than half a century these two men worked together; both received the well earned honor of knighthood, and before his death, which occurred in 1900, Sir John Lawes made provision for the permanent continuance of the work, under what is now known as the "Lawes Agricultural Trust."

The feature of the work of Lawes and Gilbert which distinguished it from anything that had previously been undertaken, except the work of Boussingault, was the combination of systematic and long continued field and feeding experiments with parallel investigations conducted in the chemical laboratory, in which the principal agricultural plants adapted to the English climate are grown both continuously on the same land and in various rotations, the composition of the crops and of the soils upon which they are grown being determined from time to time, and in which large numbers of animals have been fed over long periods and under such conditions that it was possible to determine the chemical elements consumed in the food and the proportion of each utilized by the animal. Extensive detours have also been made into other fields of chemical research, especially that of the assimilation of nitrogen by plants. For many years several general assistants have been employed, including chemists, botanists, computers and other help. The entire expense of this work has been met by the originator, except that a chemical laboratory was presented to him some years ago in recognition of the value of his work.

In 1851 a small company of Saxon farmers, organized as the Agricultural Society of Leipsic, incited by the revelations of Liebig and Boussingault (q.v.), who were then in the full zenith of their work, employed a young

chemist, Emil von Wolff, and started him in the experimental study of agricultural problems, especially those related to the feeding of animals. In a few years the government was induced to assume the cost of this work, and thus was established at Moeckern, near Leipsic, the first public agricultural experiment station in the world.

In the United States attempts at experimental research in agriculture were undertaken at the Agricultural High School, afterwards State College, of Pennsylvania; at the Michigan Agricultural College, and at the Maryland Agricultural College, all established between 1854 and 1858, and later several of the institutions organized under the National Agricultural College act of 2 July 1862, undertook some investigations of this character.

The first regularly organized agricultural experiment station in America was established at Wesleyan University, Middletown, Conn., in 1875, under the directorship of Dr. W. O. Atwater, a young chemist who had become enthused with the idea while studying in Germany. For the inauguration of this work private initiative was necessary; Mr. Orange Judd, then editor and proprietor of the 'American Agriculturist,' contributed $1,000 on condition that the State should appropriate $2,800 for the support of the station for two years. This offer was accepted and work was begun in October of that year. In 1877 at the expiration of this period the State assumed the entire support of the station, and it wa. removed to New Haven.

Similar stations were established by North Carolina in 1877; by New Jersey in 1880; by New York and Ohio in 1882; and by Massachusetts in 1883. During this period also several of the agricultural colleges organized their research work on a more definite basis, and by 1887 there were 17 stations in operation in 14 States.

In 1883 a bill was introduced in the House of Representatives of the National Congress by C. C. Carpenter, of Iowa, providing for the establishment of experiment stations in connection with the colleges of agriculture, but it was not voted upon. In the next Congress Mr. Cullen, of Illinois, introduced a bill providing for a grant of $15,000 annually to each State and Territory for this purpose. This bill was re-introduced in the following Congress by William H. Hatch, of Missouri, and after being so amended as to authorize States, in which experiment stations independent of the agricultural colleges had been previously established, to use the grant in support of such independent stations — a proviso applying to the five stations above mentioned — the bill became a law on 2 March 1887.

Under this law experiment stations have been established in every State and Territory in the United States, 50 such stations being enumerated in 1904 — the fund being divided between two stations each in Connecticut and New York; while additional stations have been established under State or territorial support in Alabama, Hawaii, Louisiana and Missouri, and in several of the States substations or test farms have been established under State support, but as adjuncts to the regular stations. In addition to these the National Government has established stations in Alaska, Hawaii and Porto Rico.

In 1904 the stations organized under the act of 1887, commonly known as the "Hatch Act," had a total income of $1,508,820.25, of which $719,999.67 was received from the National Government, the remainder, $788,820.58, coming from State appropriations, fees, sales of produce and other sources. The stations employed that year 795 persons in the work of administration and research, and published 393 annual reports and bulletins, which were sent to nearly 700,000 addresses.

The following are among the principal subjects under investigation by the American stations: (1) The soil: its physics, chemistry, and biology; including tillage, drainage, irrigation and the maintenance of fertility by crop rotation and the use of manures and fertilizers. (2) The plant: its physiology, chemistry, nutrition and pathology; the introduction of new varieties; improvement in productiveness by selection and breeding; the control of fungous and bacterial diseases and injurious insects; the various phases of forestry. (3) Animals: the special adaptations of the various breeds; the chemistry of animal foods and the economics of feeding; dairying and its manifold problems; the control of animal diseases.

In addition to the work above outlined, several States have laid upon the stations certain lines of police work, such as the inspection of fertilizers, seeds, drugs, foods and animal feeding stuffs for the prevention of adulteration; that of live stock to prevent communication of animal diseases, and that of orchards and nurseries for the control of insect pests and fungous diseases; but such work is not scientific research; it frequently interferes materially with the conduct of such research, and is more properly an executive function of the state government. In some States it is so recognized.

Under the provisions of the Hatch Act the stations are governed under the laws of their respective States, the National Government exercising no control except to make sure, through annual financial reports from the stations and through personal visits by officers of the Office of Experiment Stations of the Department of Agriculture, that the money appropriated by Congress is being expended for the purpose designated in the national law.

The stations, in connection with the colleges of agriculture, have organized an "Association of American Agricultural Colleges and Experiment Stations," which meets annually at some point in the United States for the discussion of matters pertaining to their work, and the Office of Experiment Stations publishes a monthly journal, the 'Experiment Station Record,' in which notices or summaries are given, not only of the publications of the American stations, but also of the scientific agricultural publications of the world.

While this work has been thus extending in the United States it has also spread over most of the civilized world, 728 such institutions being enumerated in other countries in a bulletin of the Office of Experiment Stations, published in 1904. The only countries in which experiment stations were not found in that year were Greece, China, Turkey, Russia, Afghanis-

tan, Beluchistan, Mexico, Central America, Bolivia, Colombia, Ecuador, Patagonia, Peru, Uruguay, and Venezuela.

The European stations as a rule are confined to single lines of investigation, and very often to inspection work merely, whereas the American station generally embraces several co-ordinate departments, each with a chief and one or more assistants and helpers, all working under the general supervision of a single director. Many of the European stations would be classed as substations in America. Another point of difference is that in Europe the stations are very generally limited to laboratory work, whereas in America, England and the English colonies the laboratories are generally used as adjuncts to field investigation.

The rapid extension of this work throughout the world and the large and constantly increasing sums of money devoted to it are sufficient evidence that it has obtained and holds the confidence of the people; but this position has been attained rather through the gradual substitution by the stations' investigations of demonstrated facts for the theories which had previously held sway in agriculture than by epoch-making discoveries, although a few of these also are to be placed to the credit of these institutions.

It was the Rothamsted Station which demonstrated that leguminous plants do not absorb and fix the free air nitrogen of the air through their foliage, a demonstration which cleared the way for the solution of a mystery which had puzzled the student of plant growth for many years, and Dr. S. M. Babcock, of the Wisconsin Station, perfected a method of determining the fat in milk, which has been adopted throughout the world, and for which a medal was voted to him by the legislature of his State; but it is the patient, plodding work, by which a body of exact knowledge in agriculture is being slowly accumulated, which has been the chief factor in winning confidence and support.

On 15 Feb. 1906 a bill, introduced by H. C. Adams of Wisconsin, passed the House of Representatives by a unanimous vote, increasing the national allotment to the experiment stations by $5,000 for each State for 1906, this amount to be increased by $2,000 annually until the total shall reach $15,000, at which amount it is to remain, thus making the total appropriations for this purpose from the general government $30,000 annually for each station.

Charles E. Thorne,
Director Agricultural Experiment Station, Wooster, Ohio.

Agricultural Machinery. See American Farm Implements.

Agriculture, in its strict signification, is the art of cultivating the earth for the purpose of causing it to produce more abundantly roots, plants, and seeds suitable for the sustenance or service of man, and for the support of the animals domesticated in his service. It was the first and has always been the most extensively practised of the arts.

In its accepted meaning, however, agriculture not only includes the tillage of the soil and the cultivation of crops, but also the rearing and feeding of all kinds of farm live stock, and in some instances the manufacture of the products of the farm into such forms as may be more convenient or more valuable for use or for sale. The manufacture of butter and that of cheese constitute recognized branches of the art of agriculture. The distinction between arable agriculture, which includes the cultivation of the ground and the growth of crops, and pastoral agriculture, which comprises merely the feeding and management of the flocks and herds of the farm, has been observed since the earliest times: "Abel was a keeper of sheep, but Cain was a tiller of the ground." In modern times, and probably in some degree at all times within the historical period, the practice of arable agriculture has been commonly associated in greater or less degree with the keeping and tending of live stock; but over immense tracts of the world's surface that are unfitted for arable cultivation the practice of pastoral agriculture still prevails, as the ancient days, wholly unmixed with the plodding labors of the husbandman.

All the great nations of antiquity which had attained to any degree of civilization, the Chinese, the Assyrians and Babylonians, the Phœnicians, and the Egyptians, appear to have held the art of husbandry in high esteem, and numerous references to agriculture and its practices are found scattered throughout all ancient literature.

The agricultural practices of Palestine are the subject of repeated allusions in the books of both the Old and New Testaments, and among the Greeks agriculture was described by such authors as Hesiod and Xenophon. The Romans attained very high perfection in agriculture, and the Latin literature devoted to this subject alone appears to have been extensive. Its authors include, among others, the names of Columella, who wrote a complete treatise on agriculture in 12 books, Vergil, whose 'Georgics' constitute the most famous of the classical poems on agriculture, as well as Varro, Pliny, and others.

It was in all probability during the Roman occupation that agriculture in Britain first attained the position of an art, but during the disturbed period of the Anglo-Saxon conquest its practice fell into inevitable neglect, and the Roman principles of culture were forgotten through disuse. When society became more settled, agriculture again revived, especially after the introduction of Christianity among the Anglo-Saxons. Under the feudal system introduced by the Normans, agriculture was long neglected in favor of war and the chase, crops were sacrificed to game, and laborers were starved that nobles might have sport. For several centuries agriculture made no progress, and its English literature did not commence till nearly 500 years after the battle of Senlac. This literature began with Sir Anthony Fitzherbert's 'Book of Husbandry,' published in 1525, which was followed half a century later by Tusser's metrical 'Five Hundred Points of Good Husbandry.'

About the middle of the 17th century the field cultivation of clover and of turnips was introduced into England by Sir Richard Weston and gradually extended. Blith's 'English Improver' was published in 1649, and the 'Legacy or Discourse on Husbandry,' by Hartlib, a follower of Cromwell, and a friend of Milton, in 1650. By the end of the century a number of other works on agriculture had been produced.

In the succeeding century still greater progress was made, of which the first steps were due to Jethro Tull, a gentleman of Berkshire, and to Lord Townshend. In Tull's 'Horse-Hoeing Husbandry,' published in 1731, was first advocated the system of sowing crops in drills or rows so wide that cultivation could be carried on between them. To Townshend belongs the credit of the introduction of the Norfolk or four-course rotation, which is still widely practised, and which has formed the basis of all the rotations of crops since adopted on light and medium land. The next great name is that of Robert Bakewell (1725-94), who discovered the method of improving live stock by judicious mating and selection. He formed the new Leicester sheep, which surpassed all pre-existing breeds in early maturity and fattening propensity, and thus exemplified the principles by which all breeds of farm live stock have since been improved. His methods were soon after applied with like success to the Southdown, the Cheviot, and other breeds. Bakewell's Leicesters were also extensively used to improve other sheep breeds by crossing. The same principles, applied in the end of the century to cattle by the brothers Colling, produced from the native Teeswater or Durham the Shorthorn, which has become celebrated as one of the valuable breeds. The improved Shorthorn has been even more extensively used in the improvement of other breeds of cattle than the Leicester in sheep. Herefords were subjected to similar selective treatment by Tomkins.

Other notable events of the 18th century were the rapid extension of the cultivation of the potato, which only attained a position of importance among field crops in England about the middle, and in Scotland in the latter half of the century. In this period were also founded the leading agricultural societies, which have exercised such a powerful influence in the education of farmers and the advancement of agriculture. These included the Highland and Agricultural Society of Scotland, founded in 1774; the Bath and West of England Agricultural Society, founded three years later; and the Smithfield Club, founded in 1793. In the same year there was established, chiefly through the exertions of the celebrated Sir John Sinclair, the first Board of Agriculture, which continued till 1816. Sir John Sinclair was its first president, and its first secretary was the famous Arthur Young, whose graphic descriptions of agricultural practices at home and abroad contributed in no slight degree to the general improvement of agriculture.

The history of American agriculture is a continuation of that of Europe so far as the methods and implements of the home-land were introduced by colonists in the New World, and with the exception of the raising of cotton and tobacco by the people of the Southern seaboard the early agriculture of the country was nothing more than the production of food for home or near-by consumption. Even so late as the beginning of the 18th century very little progress had been made, the old ways still holding their own. The development of agriculture in Great Britain and Europe, as outlined above, had its echo in America, but really substantial advance was not made until the wonderful achievements of the next century accomplished more for the world's benefit in decades than had been gained before in centuries. In considering the causes that produced this astonishing advancement and turned an industry into a science we will find in the last analysis that the prime agency was the improvement in the means and methods of transportation. The general adoption of power propulsion made it possible to market crops from lands that were otherwise outside the pale of cultivation, so the great fertile plains of the Mississippi and its tributaries, and the vast areas of Australia, Russia, and South America were added to the food-producing regions of the world. The possibility of marketing the products of these remote lands created a demand for machinery to make good the lack of laborers; then as the good soils became exhausted, or the pressure of demand necessitated additional supplies from cultivated land, the problems presented were solved by the labors of scientists, who brought chemistry to the aid of the tiller, and agriculture ceased to be a haphazard means of livelihood, becoming, even, almost independent of the vagaries of the seasons. The importance to the farmer of the application of power to the labors of the farm is shown by the statement of an official of the Department of Agriculture, who states that the amount of human labor necessary to produce a bushel of wheat was reduced in 66 years from three hours and three minutes to an average of about ten minutes, while the cost of that labor fell from 17¾ cents to 3½ cents a bushel.

The improvement in every line of human endeavor that comes through competition has not failed in agriculture, and it is no longer an acceptable reason for raising certain crops on a farm that they always have been raised there. The successful agriculturist looks upon his farm as a business plant, and strives in every possible way to get from that plant the maximum of product, fitting his crops to the peculiarities of the soil, or, if need be, fitting the soil to the requirements of the crops his market demands. Even the smallest farmer has the world for his market, for the apples raised on the hillsides of Vermont are sold in the markets of New Orleans, London, and Paris, and the small fruits and vegetables of the southern States are found in the far north at midwinter. The farmer has come to realize the value of such modern aids to business as the advertising pages of the newspapers, and it is no rare thing to find an up-country producer offering his products through the medium of the great metropolitan dailies. So agriculture has awakened with a start, and in great leaps and bounds placed herself in the front ranks of the century's progress.

The division of labor in agriculture has, as in other productive occupations, become a feature of the age. Although the farmer should still be somewhat of an «all-around man,» he no longer requires to be a plow-wright, farm-implement maker, harness-maker, woodman, etc., but may devote his entire attention to the more immediate demands of his vocation.

But farming itself has come very extensively under the influence of this division of labor, and each successful husbandman devotes his attention to a particular branch rather than attempt the cultivation of every farm product needed for home consumption. One is a wool-grower, another breeds horses or raises beef, or devotes

TWENTY-FOUR DOUBLE-ROW CULTIVATORS IN OPERATION.

his attention to dairying, or market gardening, or fruit growing, or some other specialty. Often a single crop, as tobacco, onions, potatoes, or wheat, receives his principal efforts.

Among a great variety of new and improved methods in tillage and soil improvements belonging to the century, tile drainage and sub-surface irrigation by means of pipes are instances of marked advance over old practices.

Ensilage for forage has been a long stride in the economical preparation and conservation of cattle food. By its means not only is it possible to furnish farm animals with a palatable and succulent food at all seasons, but an important saving of forage, and of labor in securing it, is effected. The introduction of silage as a cattle food marks the dawn of an intensive husbandry hitherto unknown, making it possible to increase greatly the number of animals kept on a given area, and correspondingly to increase the food supply for the human family.

The winter feeding of farm animals is no longer the task of a century ago, but has become a simple problem. Indeed, so easy has winter feeding become, that pasturage, the blessing of our fathers, has by comparison become difficult, and feeders are becoming keenly alive to the needs of a better system of summer feeding than pasturage alone affords.

Ever since the patriarch Jacob outwitted his father-in-law in the division of their flocks and herds by the use of « peeled rods,» the art of breeding has been more or less faithfully pursued. If we may judge of the results, however, this century has witnessed more progress in many directions than the 3,000 years preceding.

Practically all the improved breeds of swine belong to the more recent period. Sheep have undergone a marked transition in fleshing properties, and certain breeds have made no less conspicuous gains in the quality of their fleece. A sheep producing 52 pounds of wool in 13 months was unheard of a generation ago.

The beef breeds of cattle would hardly recognize their ancestors of a century ago as of the same race, while dairy cows of that time would forget their cud in contemplation of a Pieterje II., with a record of over 30,000 pounds of milk in a single year.

As instances of remarkable development in horses within the century may be mentioned the American trotter and the Kentucky gaited saddler. In the former instance the unnatural trot and pace, by selection, breeding, development, and training, have acquired the speed of a mile in 2 minutes 2¼ seconds and 1 minute 59¼ seconds, respectively, with a long list of performers of miles faster than 2:10. The perfection of a breed of horses taking each of five different gaits at a word from their riders, which every Kentucky gaited saddler must do, is another monument to the agricultural skill of the age.

In the diversity of talents used by husbandmen, those of the chemist play an important role. Evidence of this is found in the Wolff-Lehmann and other feeding standards. By patient study extending over a long period of time and a large number of animals, tables have been arranged showing the food requirements of all common domestic animals in all ordinary conditions of use. The chemical composition of feeding stuffs has been accurately determined. The percentages of nutrients — albuminoids, fat, and carbohydrates (starch, sugar, fibre, etc.) — digested by animals have been worked out and recorded. Numerous tests have been made to determine the most advantageous amounts and proportions of these nutrients for each of the various purposes for which animals are kept.

These results, compiled, arranged, and published, give the feeder information of inestimable value in the profitable pursuit of his vocation. These studies and investigations have not only proved of great advantage in feeding animals, but have resulted at the same time in the discovery of principles of human nutrition having an important bearing on man's subsistence.

Great strides have been made in methods of preventing and overcoming animal diseases, deserving of far more extended mention than it is possible here to make. The discoveries of Dr. Koch, resulting in the preparation of tuberculin as a diagnostic for consumption in cattle; the inoculation of cattle, rendering them immune from Texas fever heretofore considered fatal to all improved breeds; the successful potassium iodide treatment for milk fever; and a host of other discoveries,— have marked the century in veterinary achievements.

The occupation of the drover has passed away with the advent of railroad transportation of farm animals. While this belongs to the subject of commerce, it is of incalculable importance to agriculture as well. A very large share of the developments of husbandry may be ascribed to the opening up of the country by the grand facilities for transportation that now annihilate both time and space. Interstate and transoceanic traffic in live stock have recently been greatly improved by mechanical and scientific efforts until our cattle travel with a degree of safety and comfort not experienced by our human ancestors of a century gone.

It is said that among the early town records of Hadley, Mass., is an entry to the effect that the cows gave so little milk through the winter that the babies had to take cider as a substitute. Could the mothers of those babies go to Hadley now and observe the methods whereby winter has become the principal dairy season in the region, would they not feel that their lives were lived too soon?

Contrast the tedious and laborious setting of milk in shallow crocks for two days, then removing the cream with a piece of perforated tin, allowing it to sour in the kitchen, acquiring the aroma of boiled dinners in transit, churning with a dash churn and kneading by hand, with the new process of converting fresh milk into « butter for breakfast in a minute and a half.»

Co-operative butter- and cheese-making has transferred this work from the kitchen of the busy housewife to the factory of the expert, to the great advantage of the product and satisfaction of the wearied housewife.

Perhaps the most interesting achievement of all is the discovery of organic ferments which ripen or sour cream in butter-making, and the study of the specific effects of each of more than a hundred different species of these organisms upon the quality of butter. A practical side of this study is found in the present practice of selecting pure cultures of bacteria for cream-ripening, thus avoiding those forms pro-

ducing bad flavors and other undesirable qualities.

In several large establishments milk is now being modified by changing the proportions of its constituents to make it closely resemble human milk, and for other specific purposes in the feeding of infants, and it has even been made without the intervention of the cow.

During the past 40 years agricultural colleges have sprung up in each of the United States, doing work calculated to make the 20th-century agriculture far superior to that of the past.

Hand in hand with this educational work, investigations have been extended into all the varied fields of husbandry. Insects are yielding up their life's history, revealing facts suggestive of methods of protecting our interests against their ravages. Microscopic organisms reveal a power in nature till now undreamed of, disclosing among their numbers our warm friends and our most deadly foes. It has become possible to measure in heat and motion the energy in every pound of food fed to our animals. The calorimeter faithfully measures every gram of gas exhaled from balance between the intake and outgo, and notes the expenditure of energy in every movement of body or limb. Even the eccentricities of the weather are not allowed to pass unnoted. Forecasts of storm advise the haymaker to be on his guard, and frosts are not allowed to spring upon the ungathered crop unannounced.

Under their specific names the reader will find statistics for each crop, and further information on the general subject may be found under the titles AGRICULTURAL CHEMISTRY; AGRICULTURAL EXPERIMENT STATIONS; DRAINAGE; IRRIGATION, etc.

BIBLIOGRAPHY.— From the beginning of the 19th century interest in agriculture has called forth a very large number of works, both general and special, and also a long list of periodicals, some of which are devoted to individual products of the farm.

The following list of mainly American and British writings has been selected as representatives of the general subject and its main branches. Important specific works are mentioned under the particular subjects of which they treat:

General.— Allen, ‹New American Farm Book›; Bailey, ‹Principles of Agriculture›; Brooks, ‹Agriculture›; Emerson and Flint, ‹Manual of Agriculture›; Fairchild, ‹Rural Wealth and Welfare›; King, ‹Physics of Agriculture›; Loudon, ‹Encyclopædia of Agriculture›; Mortimer, ‹The Whole Art of Husbandry›; Morton's ‹A Cyclopædia of Agriculture› and ‹Handbook of the Farm›; Periam, ‹The American Encyclopædia of Agriculture›; Roberts, ‹The Farmstead›; Tull, ‹Horse-Hoeing Husbandry›; Voorhees, ‹First Principles of Agriculture›; Wilcox and Smith, ‹Farmers' Cyclopædia of Agriculture›; Young, ‹Annals of Agriculture.›

‹A History of Agriculture and Prices in England from 1259 to 1793,› by James E. Thorold Rogers (8 vols., 1866–98), is a work of immense research and monumental significance, undertaking to recover aspects of the history of the people of England which contemporary records of prices give the means of knowing. It sheds light not merely on agriculture, but on politics, political economy, etc., even education, and revolutionizes some accepted views.

Crops.— Flint, ‹Grasses and Forage›; Shaw, ‹Forage Crops Other Than Grasses,› and ‹Soiling Crops and the Silo.› For bibliography on individual crops see specific titles.

Drainage and Irrigation.— King, ‹Irrigation and Drainage›; Miles, ‹Land Drainage›; Waring's ‹Drainage for Profit and Drainage for Health›; ‹Report of the Massachusetts Drainage Commission›; and ‹Sewerage and Drainage›; Wilcox, ‹Irrigation Farming.›

Flowers, Fruits, Vegetables, etc.— Bailey's ‹Evolution of Our Native Fruits›; ‹Principles of Fruit Growing›; and Principles of Vegetable Growing›; Bailey and Miller, ‹Cyclopedia of American Horticulture›; ‹Barry's Fruit Garden›; Cara, ‹Bush Fruits›; Fuller's ‹The Nut Culturist,› and ‹The Small Fruit Culturist›; Harcourt, ‹Florida Fruits and How to Raise Them›; Henderson's ‹Gardening for Profit,› and ‹Practical Floriculture›; Lodeman, ‹The Spraying of Plants›; Nicholls, ‹A Text-Book of Tropical Gardening›; Oemler, ‹Truck Farming in the South›; Thomas, ‹American Fruit Culturist›; Waugh's ‹Fruit Harvesting, Storing, Marketing, etc.,› and ‹Systematic Pomology›; Wickson, ‹California Fruits.›

Historical.—Daubeny, ‹Lectures on Roman Husbandry›; Flint, ‹One Hundred Years' Progress›; Hoskyns, ‹Short Inquiry into the History of Agriculture›; Prothen, ‹The Pioneers and Progress of English Farming›; Rawlinson, ‹Ancient Egypt›; Rogers, ‹History of Agriculture and Prices in England›; Stephens, ‹Book of the Farm.›

Live-Stock and Dairy.— Aikman, ‹Milk, Its Nature and Composition›; Craig, ‹Judging Live-Stock›; Curtis, ‹Horses, Cattle, Sheep, and Swine›; Decker, ‹Cheese-Making›; Felch, ‹Poultry Culture›; Henry, ‹Feeds and Feeding›; Jordan, ‹Feeding of Animals›; Miles, ‹Stock-Breeding›; Robinson, ‹Poultry Craft›; Shaw's ‹Animal Breeding,› and ‹Study of Breeds›; Stewart's ‹Feeding Animals,› and ‹Shepherd's Manual›; Wallace's ‹Farming Industries of Cape Colony›; ‹Farm Live-Stock of Great Britain›; ‹India in 1887›; and ‹The Rural Economy and Agriculture of Australia and West Zealand›; Wing, ‹Milk, Its Products›; Wright's ‹New Poultry Book,› and ‹Practical Poultry Keeper.›

Manures.— Aikman, ‹Manures and the Principles of Manuring›; Griffith, ‹Treatise on Manures›; Harlan, ‹Farming with Green Manures›; Harris, ‹Talks on Manures›; Sempers, ‹Manures: How to Make and How to Use Them.›

Soil.— King, ‹The Soil›; Roberts, ‹The Fertility of the Land.›

Periodicals.— ‹American Gardening,› New York; ‹Farm and Fireside,› Springfield, Ohio; ‹Farm and Home,› Springfield, Mass.; ‹Farmer's Advocate,› London, Ont.; ‹Farmers' Review,› Chicago; ‹Farm Journal,› Philadelphia; ‹Florists' Exchange,› New York; ‹Michigan Farmer,› Detroit; ‹Practical Farmer,› Philadelphia.

Agriculture, Department of, an executive department of the United States, whose head is a member of the Cabinet with the title sec-

Photographed by Tibbits.

A COMBINED STEAM HARVESTER AT WORK IN THE FIELD.

The greatest of all agricultural machines, which heads the grain, threshes it clean, and lays it in bags in piles on the ground

retary of agriculture. It was formed early in 1889 under President Cleveland, the first secretary being Norman J. Colman, of Missouri; he was succeeded in the same year, under President Harrison, by Jeremiah M. Rusk, of Wisconsin; in 1893 President Cleveland in his second term appointed J. Sterling Morton, of Nebraska; in 1897 President McKinley appointed James Wilson, of Iowa, who still holds it (1902). Its germ was a distribution of seeds to farmers by the Commissioner of Patents in 1836, enlarged by Congress in 1839 to include the prosecution of agricultural investigations and collection of agricultural statistics; in 1854 a special appropriation was made and an entomologist employed; in 1855 a chemist and botanist were added and a propagating garden begun. In 1862 the Agricultural Bureau was established separate from the Patent Office, and President Lincoln appointed Isaac Newton, of Pennsylvania, Commissioner of Agriculture; the last Commissioner was Mr. Colman, the first Secretary. The Department's quarters in Washington are in a large park near the Washington Monument. Its functions are expressed by statute as: «To acquire and diffuse among the people of the United States useful information on subjects connected with agriculture in the most general and comprehensive sense of that word, and to procure, propagate, and distribute among the people new and valuable seeds and plants»; but scientific and administrative duties have been heaped upon it till it has become not only an enormous workshop and museum of every class of scientific research relating to plant and animal life and that of agricultural animals, but an establishment of practical services in trade and commerce, quarantine, statistics, tree-planting, road-making, irrigation, insecticides, and almost everything that can affect the interests of those engaged in raising and marketing all articles that grow from the ground or living things that feed on them. Even the Weather Bureau was transferred to it, in 1891, from the War Department. Its publication department is immense, and includes a ‹Year-Book,› regular ‹Farmers' Bulletins,› and a monthly list of publications, all sent free to applicants or obtainable through members of Congress. The periodicals, ‹Experiment Station Record,› ‹Monthly Weather Review,› and ‹Crop Reporter,› also works of more special character, are given free to scientific institutions and collaborators of the department, libraries, colleges, and experiment stations, and sold by the Superintendent of Documents. Its cost is about $4,500,000 a year, of which about $700,000 goes to the agricultural experiment stations. The detailed statement below will give a full conspectus of its activities.

Organization, Subdivisions, and Functions of the Department, 1902.

Office of the Secretary.— Supervision of public business relating to the agricultural industry and management of department subdivisions; advisory supervision over government agricultural experiment stations; control of quarantine stations for imported cattle and of interstate cattle quarantine, including inspection of cattle ships; also carrying into effect the interstate game laws and those on importation of noxious animals, with authority to control that of other animals.

The Weather Bureau.— Records daily existing atmospheric conditions and formulates therefrom — for distribution — forecasts of probable weather during the succeeding 48 hours. It maintains a central office in Washington, and about 180 subordinate stations in the United States and West Indies. It also receives daily telegraphic reports of observations in Canada, Mexico, the Azores, and the western coast of Europe.

The Bureau of Animal Industry.— Investigates the nature and prevention of communicable diseases dangerous to live stock, and takes measures for their extirpation; inspects live stock and their food products in interstate and foreign commerce, also the transport vessels for exported and quarantine stations for imported animals; disseminates information on our dairy interests and their foreign markets; and reports on our animal industries and means of improving them.

The Bureau of Chemistry.— Studies the chemical problems of agriculture: soils, fertilizers, and irrigation waters; agricultural products and industries; insecticides and fungicides; foods of man and beast; raw materials, products, and processes of agricultural-chemical industries; chemical relations which modify the results of environment — as soil, latitude, altitude, and meteorological conditions — on agricultural products; inspects food products imported or for export; and examines quality of materials used in road construction. The chemical problems of other departments are turned over to it.

The Bureau of Plant Industry.— Studies plant life in relation to agriculture, including vegetable, pathological and physiological, botanical, pomological, grass and forage plant investigations and experiments; has charge of experimental gardens and grounds, the Arlington experimental farm, Congressional seed distribution, seed and plant introduction, and tea-culture experiments.

The Office of Experiment Stations.— Supervises the expenditures of those in the United States, manages those in Alaska, Hawaii, and Porto Rico, and prepares publications chiefly based on their results, including the monthly ‹Experiment Station Record›; conducts relations with American and foreign institutions for agricultural education and research; and supervises special investigations ordered by Congress, in co-operation with the agricultural colleges and experiment stations.

The Bureau of Forestry.— Prepares and executes plans for conservative lumbering of woodlands, public or private; investigates trees and methods for planting, and gives practical assistance to tree-planters; studies commercially valuable trees for their special uses in forestry, and the relations between forests and fire, grazing, lumbering, stream flow, and irrigation; maintains a photographic laboratory and collection and a library.

The Bureau of Soils.— Studies physical and chemical properties of soils, and materials and methods of artificial fertilization, with their influence on the original soils; classifies and maps soils in agricultural districts to show the distribution of soil types for adaptability to certain crops and their management; investigates alkali problems and their relations to irrigation and seepage waters; reclamation of abandoned lands; studies tobacco soils and methods of cultivation

and curing, introduction of improved varieties, and methods of exporting tobacco.

The Division of Statistics.— Collects and digests statistics of agricultural production; area annually sown to each of the leading crops, their condition on the first day of each month, the quantitative results at close of the crop year, and estimated farm value 1 December. Supplementarily it collects periodical information on minor crops of importance, meadows and pastures, and the principal foreign crops. The stock of corn, wheat, and oats on United States farms at certain regular fixed dates is estimated, with the proportion shipped out of the county where grown; the number and value, by species, of animals on United States farms at the beginning of each year, and the annual losses from disease and exposure; also the annual clip of wool and average weight of fleeces, by States and Territories. It computes the world's production of the chief crops, by countries, and prices of principal agricultural products in various United States markets.

The Division of Publications.— This is the publishing house of the Department. It has general charge and assignment of expenditures under the appropriation for printing and distributing agricultural documents, preparation and distribution of the ‹Year-Book,› ‹Farmers' Bulletins,› and other bulletins, reports, and circulars; supervises the Department's printing and binding in the Government Printing Office; prepares the drawings for illustrations; and prepares and distributes official information and advance notices to agricultural writers.

The Division of Entomology.— Studies the entire field of insect life in its relation to humanity; primarily, insects injurious directly to man, to agriculture and horticulture, and to stored products; the geographic distribution of such insects, and their relations to climate. It conducts field and laboratory experiments with different classes of remedies, and reports thereon. It also studies beneficial insects — both those which are the source of industries, like the honey-bee, the silkworm, and the fig-fertilizing insect and those indirectly beneficial by preying on injurious ones. It makes large collections of insects and of insecticidal machinery and chemicals.

The Division of Biological Survey.— Studies the geographic distribution of animals and plants, and maps the natural life zones of the country; also investigates the economic relations of birds and mammals, recommends measures for the preservation of beneficial and the destruction of injurious species, and carries into effect the Federal laws concerning the importation of wild birds and other wild animals, and the interstate game laws.

The Office of Public Road Inquiries.— Investigates the United States system of road management, and the best methods of road-making and maintenance; experiments on best methods of road-building, and analyzes chemical and physical qualities of road materials; co-operates with agricultural colleges, experiment stations, and local authorities, in building short sections of road as object lessons, etc.

The Section of Foreign Markets.— Has for object the extension of our agricultural export trade. It studies foreign conditions of demand and supply (using chiefly foreign official statistics of production), and imports and exports, supplemented by details obtained from consular reports, trade journals, and other sources. In cases of special importance a representative of the office is sent to obtain by personal investigation the information needed.

The Division of Accounts and Disbursements. — Audits and pays all accounts and adjusts claims against the Department; decides questions involving the expenditure of public funds; prepares advertisements, schedules, and contracts for annual supplies, leases, agreements, letters of authority, and all letters to the Treasury Department and Department of Justice; issues requisitions for the purchase of supplies, and requests for transportation; prepares the annual estimates of appropriations; etc.

The Library.— The librarian purchases books and periodicals, supervises their arrangement and cataloguing, and has charge of the preparation of catalogues, indexes, bibliographies, and similar publications.

Agrigentum, ăg-rĭ-jĕn'tŭm, a town in Sicily, of which this was the Roman name, the Greek name having been Akragas and the modern Italian name being Girgenti. It is thought to have been founded by Dorian colonists about 582 B.C. Its situation on the southern shore of the island was peculiarly strong and imposing, standing as it did on a bare and precipitous rock about 1,000 feet above the level of the sea. During the Greek period Agragas rose to a position of great wealth and importance, and was adorned with splendid temples and public buildings. Among Sicilian towns it was second only to Syracuse. In 406 B.C. the city received a blow from which its dignity and power never recovered, in its capture by the Carthaginians. Under the Roman dominion we do not hear much of the town, which, however, seems to have been always prosperous, having mines as well as the most fertile territory. The town is celebrated in Greek history as the birthplace of the famous philosopher Empedocles, and the celebrated and almost legendary tyrant Phalaris was ruler there,— in what capacity is not clearly recorded. In the history of fine art Akragas was famous as the centre of a school of sculpture and refined architecture. We still have vestiges of this in the extraordinary group of temples, that dedicated to Hera Lacinia; that called "Temple of Concord," a remarkably well-preserved monument of the Doric style; that called "Temple of Hercules," much ruined; and, finally, the gigantic Temple of Zeus, a building wholly unique in Grecian art as having columns engaged in the walls of the cellar and a great interior evidently treated as a public hall, and differing in this way from all other Hellenic temples.

Ag'rimony (*Agrimonia*), a genus of plants belonging to the natural order *Rosaceæ*, distinguished from the other genera of the same tribe (*Roseæ*) by having but two carpels enclosed in the deep tube of the calyx, from 7 to 20 stamens, and small notched petals. *A. eupatoria*, or common agrimony, is an erect, hairy, herbaceous plant found on the borders of fields and woods, by the wayside, etc., probably escaped from gardens, as it is not a native of the United States.

Agrippa, Herod. See HEROD AGRIPPA.

Ague. See MALARIA.

Aguilar, ā-gē-lar', **Grace,** an English writer: b. in Hackney, 2 June 1816; d. in Frankfort, 16 Sept. 1847. Of Jewish parentage, she at first devoted herself to Jewish subjects, but her fame rests on her novels, ‹Home Influence,› ‹A Mother's Recompense,› ‹Home Scenes,› and ‹Heart Studies,› etc., most of which were published posthumously under the editorship of her mother.

Aguilar de la Frontera, fron-tā'rä, Spain, a town of Cordova province, Andalusia; 26 m. S. by E. from Cordova. It has three good squares and several handsome public buildings, and in the time of the Moors was defended by a strong castle. The inhabitants are employed in agriculture, stock-raising, manufacturing, and in quarrying lime, gypsum, and freestone. Pop. about 14,000.

Aguil'arite, a native sulpho-selenide of silver, having the formula $Ag_2S.Ag_2Se$. It is found at Guanajuato, Mex.

Aguilas, ä-gē'läs, Spain, a flourishing seaport in Murcia province, about 37 m. to the S.W. of Cartagena, with copper and lead smelting works. It carries on considerable trade in ores, etc. Pop. 15,000.

Aguilera, Ventura Ruiz, ä-gē-lā'rä, ventoo'rä roo'ēth, lyric poet, «the Spanish Beranger»: b. Salamanca, 2 Nov. 1829; d. Madrid, 1 July 1881. After a medical course at home he became a Madrid journalist (1843) and an important official under Liberal governments; later a director of the Madrid Archæological Museum. His bold incisive editorials endeavored to instil fervid national patriotism into the masses, an aim also of his poems like «National Echoes» and «Satires.» His «Elegies» (1862) were masterpieces translated into nearly all European languages. He wrote also ‹The Book of the Fatherland› (1869); ‹A Christmas Legend› (1872); ‹The Modern Arcadia›; collections of novelettes, etc. Complete Works, Madrid, 1873.

Aguinaldo, ä'gē-näl-do, **Emilio,** the leader of the insurgents in the Philippine insurrection of 1896, and their chief in the Spanish-American war of 1898: b. in Imus, 1870. A Chinese mestizo, of Chinese and Tagalog parentage. His father was a planter and he received his early education at the College of St. Jean de Lateran and the University of St. Tomas in Manila. Later he became the protégé of a Jesuit priest, and was for a time a student in the medical department of the Pontifical University of Manila. In 1888 he had some trouble with the authorities and went to Hong-kong. Young Aguinaldo there became interested in military affairs and gained a knowledge of warfare. He learned something of the English, French, and Chinese languages, together with various native tongues. He achieved a reputation for intelligence, ability, shrewdness, and diplomacy, and had a personal magnetism which gave him influence among his countrymen. On the outbreak of the rebellion against Spanish authority in 1896 Aguinaldo became a commanding figure with the insurgents. He was at the head of the diplomatic party, which succeeded in making terms with the Spanish government, the latter paying a large sum to the Philippine leaders to lay down their arms. Aguinaldo quarreled with his associates in Hongkong over the division of this money, and went to Singapore, where he came in contact with the United States consul shortly before the breaking out of the war between the United States and Spain. On the representations of the consul Commodore Dewey telegraphed to have Aguinaldo sent to him. The insurgent leader arrived at Cavité shortly after the battle of Manila Bay. Aguinaldo was given opportunity to organize the Filipinos against the Spanish authority; but no promises were made to him and the insurgents were never officially recognized by the Americans. Friction early arose and the Americans protested against the cruel treatment of Spanish prisoners by the Filipinos. The strain became serious at the capture of Manila, the insurgents claiming the right to sack the city, which the Americans denied. On 12 June 1898 Aguinaldo organized a so-called Filipino Republic, with himself as president, but very soon proclaimed himself dictator. He protested against the Spanish-American treaty of peace, which ceded the Philippine Islands to the United States, and claimed the independence of the islands. He organized an extensive conspiracy among the native population of Manila, and ordered the complete massacre of the Americans, together with the entire European population of the city, while yet at peace with them. The plot was discovered in time and failed. The intention of Aguinaldo to oppose by force the American occupation had been growing increasingly evident, and on the evening of 4 Feb. 1899 his forces attacked the American lines in the suburbs of Manila. The news of this overt action caused the prompt ratification of the Spanish-American treaty by the United States Senate. Aguinaldo made a determined resistance to the Americans, and the rainy season soon prevented the latter from following up their uniform successes in the open field; but early in 1900 the organized insurrection, which was chiefly confined to the Tagalog nationality, was broken up, Aguinaldo driven into hiding, and his correspondence, order books, etc., were captured by Gen. Funston, who captured Aguinaldo himself at Palawan, Luzon, 23 March 1901. On 2 April he took the oath of allegiance to the United States. In January 1903 he sent a petition to Congress on the terrible conditions of famine and pestilence in the island.

Agulhas, ä-gool'yäs, **Cape,** the most S. point of Africa, lies about 100 m. E.S.E of the Cape of Good Hope, in lat. 34° 49' S.; lon. 20° 0' 40" E. The point is very dangerous for ships; fogs are frequent, the currents are uncertain, and there are many rocks to seaward. In 1849 a lighthouse was erected on the point. The Agulhas bank extends along the whole southern coast of Africa, from near Natal to Saldanha Bay. It has an average breadth of 40 miles, but is difficult of navigation. The waters abound in fish. Agulhas (Portuguese) means needles.

Agustite, a name given by Trommsdorf to a variety of apatite occurring in Saxony, and supposed by him to contain a new earth, named in German *augusterde*.

Aguti, á-goo'ti (Fr. through Sp. from the native name), a gregarious South American and West Indian rodent,— any species of the genus *Dasyproctidæ*. Agutis are destructive to crops, particularly to sugar-cane; they are forest-dwellers, living in holes, but they come out into the fields, usually at night, to feed. In some regions they are considered edible; in Brazil a species, the «pampas hare,» is hunted as game, and the others are hunted with a view to saving the crops. About the size of a rabbit, they more resemble squirrels, for their legs are long and thin, their ears short and round, their claws hoof-like, and tail stumpy. The tail and the hinder part of the body are covered with the long stiff hairs from which the genus is named. The spelling of the name is varied to acouchi, acouchy, agouti, agouty, and aguchi; in Guiana and the West Indies a species is called «achouchy» or «achuchi.» The same name has been applied to a species of cavy (q.v.).

Ahab, king of Israel 875–853 (?) B.C., son and successor of Omri (1 Kings xvi.–xxii.). He found his kingdom in extreme peril: whole districts in the north had been swallowed up by the growing Syrian kingdom with capital at Damascus, which menaced its very life; and Moab and Edom were possessions only to be held down by force, with Syria constantly inciting them to revolt. He proved a prince of great energy and ability: twice he drove back Ben-hadad of Damascus, and he held down Moab with a strong hand, crushing a wholesale insurrection, as proved by the inscription on the Moabite Stone (q.v.); he made the kingdom of Judah an ally and perhaps a vassal, and gained at least the neutrality and perhaps some of the resources of the kingdom of Tyre by marrying the Princess Jezebel. Unfortunately this involved letting her establish the worship of the Tyrian Baal, called Melkart, and made the extremists of the Yahwé priesthood his irreconcilable enemies and defamers. Yet he was no deserter of Yahwé, but merely a cool politician, who felt that his first duty to his country and even to its national religion was to save it from absorption in Syria, which would end Israel and the Yahwé cult at once; and 400 priests of Yahwé prophesied before him previous to his last campaign. His entire internal policy has been blackened by the affair of Naboth's vineyard, and Jezebel is a name of execration. Certainly the judicial murder was a great crime, but it shows at least that even an Oriental monarch 2,750 years ago could not expropriate an obstinate holder by sheer violence; defiance of royal orders was not as safe to let go for a precedent then as now; and more than one king has had his hand forced by his queen. Nor in fact did these things prejudice the larger interests of his reign. In 854 we find him strangely allied with his old enemy Ben-hadad against Shalmaneser (q.v.) of Assyria, though one would suppose he would gladly have seen Ben-hadad crushed, and Assyria was no immediate danger: possibly he was menaced from other quarters and dared not refuse. At any rate, Shalmaneser inflicted a crushing defeat on the allies at Karkar near the Orontes in 854, and Ahab recovered liberty of action if he had lost it: for the next year he engaged in a new campaign against Ben-hadad, in alliance with Jehoshaphat, king of Judah, and was killed in battle. The Biblical narrative is taken from two opposed sources: one embodying the popular tradition of Ahab as a brave, capable, and popular king, the other the priestly view of him as a bad man and monarch. His contest with Elijah (1 Kings xvii.–xix.) is a picturesque rendering of the latter.

Ahasue'rus, Scripture history, a king of Persia, the husband of Esther, to whom the Scriptures ascribe a singular deliverance of the Jews from extirpation, which they commemorate to this day by an annual feast, that of Purim, preceded by what is called the fast of Esther. Different opinions have been entertained as to which of the kings of Persia mentioned in other historical books may be the Ahasuerus of the Bible. He is probably the same as Xerxes. Ahasuerus is also a Scripture name for Cambyses, the son of Cyrus (Ezra iv. 6), and for Astyages, king of the Medes (Dan. ix. 1). The word Ahasuerus is merely the Latin form of the Hebrew Ashashverosh, and is believed by some to be a transcription of the Persian Khshayarsha ("venerable king"), and this name may be reasonably supposed to have been originally an appellative, so that its application by foreigners, like the Jews, to different royal personages is explained.

Ahaz, the 12th king of Judah, succeeded his father Jotham, 742 B.C. Forsaking his father's religion, he gave himself up so completely to idolatry that he is said to have caused his own son to pass through the fire to Moloch, and plundered the temple to obtain presents for Tiglath-pileser, king of Assyria, whose assistance he desired to obtain. His powerful ally freed him from his most formidable foes by invading Syria, taking Damascus, killing Rezin, the king, transporting the inhabitants to Kir, thus putting an end to the Syrian kingdom of Damascus, and by stripping Israel of the whole country east of the Jordan.

Aiken, S. C., city and county-seat of Aiken co., on the Southern Railroad, 17 m. N.E. of Augusta, Ga., and 120 m. N.W. of Charleston. It is one of the most picturesque and attractive towns in the United States, being located at an elevation of 600 feet above the sea, in the midst of numerous pine forests. The dryness of the atmosphere and the comparative mildness of the climate have combined to make Aiken the most noted health resort in the South. The town is the centre of a large and important agricultural district. There is located here the Aiken Institute for white students; the Schofield Normal and Instructive School and Immanuel Training School for colored youth, and several private schools, and academies for both sexes. Many Northern families of wealth and culture have winter homes here. Aiken was first incorporated in 1835, and is governed by charter, secured in 1890 and revised in 1897, which provides for a mayor elected every two years, and a city council composed of the mayor and six aldermen. The town officials are elected annually at town meetings. The water supply and sewerage system are controlled by the town. There are two national banks here, numerous large hotels, a number of manufactories, and several newspapers. Pop. (1890) 2,362; (1900) 3,414.

Aikinite. See Needle Ore.

Ainsworth, Frederick Grayton, American soldier: b. Woodstock, Vt., 11 Sept. 1852. He was appointed first lieutenant and assistant surgeon, U. S. A., in 1874; major and surgeon 1891; colonel and chief of Record and Pension Office in 1892, where he introduced the index-record card system by which 50,000,000 cards made the military and medical record of any soldier at once accessible. In 1899 he was appointed brigadier-general, and made editor of the "Official War Records."

Ainsworth, William Harrison, an English novelist: b. 4 Feb. 1805; d. 3 Jan. 1882. He was the son of a Manchester solicitor. He wrote 'Rookwood' (1834); 'Jack Sheppard' (1839); and about 40 other novels, including 'Guy Fawkes,' 'Tower of London,' 'Windsor Castle,' 'Lancashire Witches,' 'Flitch of Bacon,' etc.

Ainus. See JAPAN.

Air, the gaseous substance that envelops the earth and forms its atmosphere. (See ATMOSPHERE.) It consists almost entirely of the gases oxygen and nitrogen, which are merely mixed and not chemically combined; but in addition it contains many other substances in small amounts, among which are water-vapor, carbon-dioxid, nitric acid, ammonia, ozone, argon, neon, and organic matter, as well as dust, germs, and other solid particles held in suspension. In certain localities other components may occur. Near the sea, for example, salt can always be detected in it, and over the land it contains sulphates in small amounts. The quantity of water-vapor present in air varies greatly with time and place, and in all analyses and statements of its composition the water-vapor is supposed to have been removed first. The quantity of carbon-dioxid is subject to considerable variation also. It is very constant in the open country, where it constitutes about 0.043 per cent (by weight) of the air; in cities the percentage is higher, rising to 0.07 and occasionally to 0.10. In crowded rooms, especially where artificial lights are burning, the quantity of carbon-dioxid present may be even greater than this. In country air the percentage of carbon-dioxid is subject to a diurnal change amounting to about one-eighth of its total amount, more being present at night than in the daytime. This is undoubtedly due to the fact that plants absorb the gas by day and exhale it during the night. The proportion of nitrogen and oxygen in air is subject to variation also, though within much narrower limits. In general, 100 volumes of air contain about 21 volumes of oxygen and 79 of nitrogen. Regnault analyzed air collected in different parts of the world, and found that the volume-percentage of oxygen in the air of Europe varied from 20.903 to 21.0 per cent. The average of 17 samples collected from over the arctic seas gave 20.91 per cent. Regnault was of the opinion that sea air contains slightly less oxygen than land air; but Lewy considered that no distinct difference could be proved except in the tropics, where sea air exhibited a slight diurnal variation. Argon constitutes about 1 per cent of air, and neon about 0.001 per cent. The nitric acid present in the air is so small in amount that it can be detected only in rainwater, by which it is dissolved and brought down. It is very likely formed partly by the direct combination of oxygen and nitrogen under the influence of electric discharges, and partly by the action of ozone upon ammonia. The quantity present is greatest in summer and least in winter. The ammonia of the air occurs partly as carbonate and partly as nitrate. Its amount is exceedingly variable, ranging from 0.1 to 135.0 parts (calculated as carbonate) in 1,000,000 parts of air, the average amount being perhaps 6. The amount present decreases during a heavy rain, but within a few hours it returns to the normal amount again. No ozone can be detected in city air, and air over marshes and in malarial regions contains very little of it. Normal country air contains not more than one volume of this gas to 700,000 of air. It is more abundant in summer than in winter, and is most noticeable during thunderstorms and heavy winds. In the laboratory ozone is produced by the action of electric discharges upon oxygen, and it is probably produced in the air in the same way. Hydrogen peroxid has been detected in the air, and some authorities consider that it may be present in greater abundance than ozone, and that it may sometimes be mistaken for ozone. (For further information on the composition of the air, see Angus Smith's 'Air and Rain.') According to Regnault, one cubic centimeter of air that has been freed from water-vapor, carbon-dioxid, and ammonia, weighs 0.0012932 gramme when the air is at the temperature 0° C., and under a barometric pressure of 760 millimeters of mercury at Paris (lat. 48° 50′ N.), and at a height of 60 metres above the sea. In English equivalents this means that at ordinary atmospheric pressure and at the temperature of melting ice (32° F.) a cubic foot of air weighs 0.080681 pound; «ordinary atmospheric pressure,» signifying the pressure that would be exerted by a weight of 14.7 pounds, resting upon a base one inch square at sea level in the latitude of Washington. When a mass of air, originally at atmospheric pressure and at the freezing-point (32° F.), is heated to the boiling-point (212° F.) without changing its volume, its pressure becomes 1.36728 atmospheres according to Balfour Stewart, or 1.36706 according to Wiebe and Böttcher. The average of these is 1.36717, which agrees well with the value 1.36719 as given independently by Morley and Miller. The older estimates of Regnault and Magnus are probably too small. The specific heat of air (the pressure being kept constant) is 0.2375 according to Regnault, and 0.2389 according to Wiedemann. The specific heat (the volume being kept constant) is 0.1715 according to Joly's direct measurement with the steam calorimeter. Air cannot be liquefied by any pressure whatever so long as its temperature is higher than about 220° F. below zero (−140° C.); but if it be first cooled to a temperature slightly below this it condenses to a liquid upon the application of a pressure of 39 atmospheres. (See CRITICAL POINT.) If it be cooled to a temperature materially lower than 220° F. below zero, it can be liquefied by a correspondingly smaller pressure. Liquid air is opalescent at first, probably from particles of solid carbon-dioxid held in suspension. These can be separated by filtration, or they will rise to the surface in a short time, leaving the clear, transparent air beneath. When liquid air is ex-

posed in a glass vessel it absorbs heat rapidly from surrounding objects, and boils actively until it has entirely evaporated. The nitrogen that it contains evaporates faster than the oxygen, however, and the liquid remaining in the vessel becomes increasingly rich in oxygen until toward the last it consists almost entirely of that gas. Liquid air may be frozen to a clear, transparent solid by surrounding it with liquid oxygen and then forcing the evaporation by means of an air-pump. Liquid air is of great interest to the physicist for many reasons; but its importance in the arts has been grossly exaggerated. In particular, the project that is put forth from time to time, to utilize liquid air for running a motor that shall condense more liquid air than it consumes, is impossible of realization, because although such an action would not necessarily imply perpetual motion it would violate the second law of thermodynamics. (See THERMODYNAMICS.) If liquid air is confined and allowed to become warm through the absorption of heat from its surroundings its expansion gradually generates an enormous pressure. This fact, together with the safety with which liquid air can be handled, has led to its use to a limited degree for blasting in tunnels and mines, where the presence of the irrespirable products of combustion of ordinary explosives is objectionable; but even this application has been discontinued, owing to certain grave and apparently insuperable practical difficulties that were encountered. See LIQUID AIR.

The scientific study of the air has been much stimulated in recent years by the establishment of the Hodgkins Fund. In October 1891 Mr. Thomas George Hodgkins of Setauket, N. Y., made a donation to the Smithsonian Institution, the income from a part of which was to be devoted to the «increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man.» The first prize of $10,000 from this fund was awarded on 6 Aug. 1895 to Lord Rayleigh of London, and Prof. William Ramsay of University College, London, for their discovery of the previously unknown element argon in the atmosphere. (See ARGON.) A prize of $1,000 was also awarded at the same time to Dr. Henry de Varigny of Paris, for his 'L'Air et la Vie' («Air and Life»), which was considered to be the best treatise upon atmospheric air, its properties, and relationships. Further information concerning the Hodgkins Fund may be had from the Smithsonian Institution, Washington, D. C. (For information concerning dust and germs, see Tyndall's 'Fragments of Science,' and Dr. T. Mitchell Prudden's 'Dust and Its Dangers.')

Dephlogisticated Air, in the old chemistry, was air that had been deprived of phlogiston (q.v.); in modern terminology it is called oxygen. Fixed air was Dr. Black's name for carbon-dioxid, suggested by the fact that certain alkaline substances can «fix» this gas, or combine with it to produce a solid substance.

The word «air» also occurs as an element in a host of compound words. The significance of many of these is evident, but some few call for special mention, and they will be found below in their respective order.

A. D. RISTEEN, PH.D.,
Editorial Staff, 'Encyclopedia Americana.'

Air, in music (in Italian, *aria*), means a continuous melody in which some lyric subject or passion is expressed. The lyric melody of a single voice, accompanied by instruments, is its proper form of composition. Many of the Italian airs of the present, together with too great a proportion of the popular music of the day, are destitute of meaning and character. The song-writers of Germany strive to construct their airs in direct conformity to the meaning of the words. Air is also the name often given to the upper or most prominent part in a concerted piece, and is thus equivalent to treble, soprano, etc. *Arietta* signifies a short, less elaborate air than *aria*, and is designed to express a more simple and transient emotion.

Air-bath, an apparatus designed for drying substances by exposing them to air of any desired temperature.

Air Beds and Cushions, often used by the sick and invalids, are composed of india-rubber, or of cloth made air-tight by a solution of india-rubber, and when required for use filled with air, which thus supplies the place of the usual stuffing materials. They tend to prevent bed-sores from continuous lying in one position. They are also cheap and easily transported, as the bed or cushion when not in use can be packed in small compass to be again inflated with air when wanted.

Air-bladder. See FISH.

Air-blast, a stream of air, issuing from a nozzle or other aperture under pressure. Such blasts are used for throwing sand or other abrasive material against a body that is to be eroded or polished; for forcing the fires of forges or furnaces, and for burning out the impurities in pig iron in the manufacture of Bessemer steel; for removing dust from grinding-machines and saws; for cleansing woven fabrics; and for multitudes of other purposes.

Air-box, a flue or other form of conduit conveying air to or from a furnace or into a mine for ventilation.

Air Brake, a mechanical apparatus, by which the expansive force of compressed air is employed to stop or control the speed of railroad trains. The air brake, in its present perfected and efficient form, not only represents the result of the remarkable progress of railroad operation during the last quarter of the 19th century, but has also contributed in no small degree to the character of the development of railroad practice. The air brake has developed into its present form through a series of stages, each of which was dictated by the occurrence of new conditions; and the modification of the air brake to meet such conditions has, in each case, enlarged the field of progress in railroad transportation. The original conception, and practically every succeeding improvement, of the air brake has been due to the quick perception and ingenuity of George Westinghouse, so that a review of the development of the Westinghouse air brake forms practically the history of the art. In the course of its development, the air brake has become known in four different forms — the straight air brake, the automatic air brake, the quick-action automatic air brake, and the high-speed air brake — each fulfilling the requirements of its day and forming the foundation of the structure of the next succeeding form.

The Straight Air Brake.— The straight air brake was the earliest and simplest form and was introduced by Mr. Westinghouse about the year 1869. An air compressor was attached to and operated by steam from the locomotive, and compressed atmospheric air into a storage reservoir, also located upon the locomotive. A line of ordinary gas or water pipe, commonly called the train pipe, extended from the reservoir through the engineer's cab and back underneath the tender and each of the cars of the train. Between the cars, the train pipe was connected, by means of rubber hose and suitable couplings, so as to form a continuous line throughout the length of the train. Near the centre of each car was placed an air cylinder, called the brake cylinder, which was connected by means of a short branch pipe with the train pipe. The brake cylinder contained a piston with a stem which was connected, through a system of levers and rods, with the brake shoes which were to be applied to the car wheels to check the motion of the train. In the cab, and within reach of the engineer, an operating valve, consisting of a three-way cock, was placed in the line of the train pipe. By means of this valve, the engineer could permit air to flow from the reservoir into the train pipe and connected brake cylinders, thereby forcing out the pistons and applying the brake shoes to the wheels. When sufficient air pressure to meet the requirements of the occasion had thus been admitted to the brake cylinders, the engineer could move the handle of his operating valve into such a position as to cut off further flow of air from the reservoir and to retain within the brake cylinders so much air pressure as had already been applied. By moving the handle of the operating valve into still another position, the engineer could cause the air already accumulated in the train pipe and brake cylinders to be discharged, through the operating valve, into the atmosphere, thereby releasing the pressure of the brake shoes upon the car wheels.

Control of the Air Pressure.— By means of this apparatus, the degree of air pressure in the brake cylinders, and, consequently, the pressure of the brake shoes upon the wheels, could be varied by the engineer from such a moderate application as would be required for checking the speed of the train upon descending grades or in bringing the train gently to a stop at stations, to the most powerful application required when an immediate stop of the train is demanded. This form of air brake came into quite extensive use upon the comparatively short passenger trains of that period. As the length of the trains became increased, however, it was found that a serious loss of time occurred in the operation of applying the brakes, because of the fact that all the compressed air for operating the brake cylinders of the different cars must travel back throughout the length of the train pipe from the storage reservoir to the brake cylinders, which operation was seriously retarded through the frictional resistance presented by the walls of the train pipe to the rapid passage of such a considerable quantity of compressed air. Also, in the case of the accidental detachment of a portion of the train while in motion, the brakes upon the detached cars were no longer capable of being applied by the engineer. Again, if the rubber coupling hose burst, or if any other portion of the apparatus became ruptured, the escape of the compressed air at such a point prevented the effective application of the brakes, and the control of the train was thereby lost.

The Automatic Air Brake.— The automatic air brake, introduced by Mr. Westinghouse in 1876, was designed to remedy the defects of the earlier system and to meet the advancing requirements of the time. The apparatus consisted of that already employed in the straight air-brake system, with the addition upon each vehicle of a storage reservoir, of sufficient capacity to supply the brake cylinder upon that vehicle, and a valve mechanism, called a triple valve, operated by variations in the air pressure in the train pipe, to control the operation of the brake cylinder. This triple valve was placed in the branch pipe leading from the train pipe to the brake cylinder, and was also supplied with a pipe leading to the new storage reservoir. It was called a triple valve because it performed the three functions of (1) permitting air to flow from the train pipe into the storage reservoir, for the purpose of charging the latter with air pressure; (2) causing the compressed air to flow from the reservoir into the brake cylinder, for the purpose of applying the brakes, and (3) permitting the compressed air to escape from the brake cylinder to the atmosphere, to remove the pressure from the brake cylinders and thereby release the brakes. The storage reservoir upon the locomotive became thereafter known as the main reservoir, and those upon the individual cars became known as auxiliary reservoirs. The characteristic feature of the automatic air brake is the triple valve, under the immediate control of which are all the operations of the brakes upon individual cars.

The triple valve, with the parts in their normal positions when the brakes are not applied, is illustrated, in section, in Fig. 1. The location of the several connections for the branch pipes to the train pipe, the auxiliary reservoir and the brake cylinder are indicated. A piston *a* is adapted to move backward and forward in a piston chamber, from which the piston stem *b* extends forward into a somewhat smaller valve chamber, containing a slide valve *c*, which is loosely confined between two shoulders upon the piston stem. Within the slide valve *c*, there is a small poppet valve *d*, called the graduating valve, which is secured by a pin to the piston stem *b*. When compressed air is admitted into the train pipe from the main reservoir by the

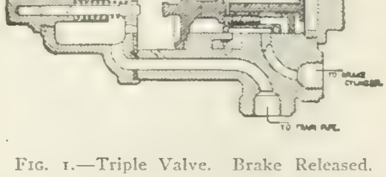

Fig. 1.—Triple Valve. Brake Released.

engineer, it enters the triple-valve structure through the passageways leading to the left of the piston *a*, where its pressure forces the piston and its accompanying parts into the positions shown in Fig. 1, if they were not already

in those positions. In this position of the piston, the small feed grooves *h* and *i* permit the compressed air to gradually pass from the train pipe, around the piston, into the valve chamber, and thence into the auxiliary reservoir, which thus becomes ultimately charged with the same pressure of air that exists in the train pipe. The brake apparatus is now in operating condition.

To apply the brakes, the engineer discharges a portion of the air contained in the train pipe, through his operating valve, whereby the air pressure in the train pipe and the chamber at the left of the piston *a* is more or less reduced. Owing to the inability of the compressed air in the auxiliary reservoir to pass rapidly out through the small feed grooves *i* and *h*, the superior pressure remaining in the auxiliary reservoir and valve chamber forces the piston *a* to the left, thereby first cutting off communication between the auxiliary reservoir and the train pipe through the feed groove *h*, and simultaneously withdrawing the graduating valve *d* from its seat in the slide valve. The shoulder at the end of the piston stem *b* then comes into contact with the end of the slide valve *c*, which subsequently accompanies the piston in its progress toward the left, until the latter is finally arrested by coming into contact with the stem *j*, which is supported in the position shown by a spring called the graduating spring. The positions of the parts are then as shown in Fig. 2.

Compressed air from the auxiliary reservoir now passes through a transverse port *e* in the slide valve, the passageway uncovered by the removal of the graduating valve *d* and the passageway *f* and connecting pipe to the brake cylinder, where it forces out the brake-cylinder piston and causes the brake shoes to be applied to the wheels. The discharge of air from the auxiliary reservoir into the brake cylinder necessarily results in reducing the air pressure in the auxiliary reservoir and valve chamber of the triple valve, and such discharge and reduction of air pressure continues until the pressure has become slightly below that of the air remaining in the train pipe and the connecting chamber at the left of the triple-valve piston. The slight preponderance of pressure then existing upon the left face of the piston *a* causes it to move to the right until the graduating valve *d* becomes seated in the slide valve and thereby prevents further discharge of air into the brake cylinder. The air pressure then existing in the brake cylinder causes the brake shoes to remain applied to the wheels, with a corresponding retarding effect upon the car.

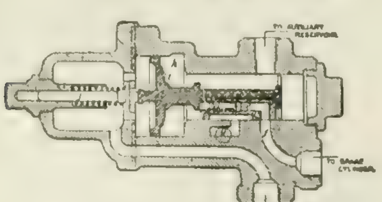

Fig. 2.—Triple Valve. Brake Applied.

Graduating the Pressure.— Should it appear to the engineer that an increased retarding force of the brakes is desirable, he discharges a further portion of the air remaining in the train pipe, through his operating valve. This results in a further reduction of the air pressure in the train pipe and the connecting chamber at the left of the piston *a*, whereupon the preponderating pressure in the auxiliary reservoir and chamber at the right of the piston causes it to again move to the left, until stopped by the stem *j*, thereby moving the graduating valve *d* and reopening the passage through the slide valve for the further discharge of air from the auxiliary reservoir into the brake cylinder. This discharge continues until the air pressure in the reservoir and chamber at the right of the piston *a* has become again reduced to a point slightly below the pressure yet remaining in the train pipe, when the preponderance of the latter upon the left face of the piston moves it inwardly and once more cuts off further discharge of air to the brake cylinder, by reseating the graduating valve *d*. This process, customarily called graduating, may be again repeated by the engineer, if the air pressure in the brake cylinder is still found by him to be insufficient to meet the demands of the occasion. In this manner, the engineer is enabled to apply the brakes with any of the various degrees of force required under the variable conditions calling for checking the speed of the train or for bringing it to a smooth and gentle stop at stations.

To discharge the air from the brake cylinder and release the brakes, the engineer moves the handle of his operating valve into the position for restoring communication between the main reservoir and the train pipe. The air pressure in the train pipe is thereby elevated, and, acting upon the left face of the triple-valve piston, moves it, with its connected valves, to the right, until it again reaches the position shown in Fig. 1. In this position of the slide valve, the passageway *f*, connected with the brake cylinder, is brought into communication, through a cavity in the lower face of the slide valve, with a port and passageway *g* leading directly to the atmosphere. The air in the brake cylinder thereby discharges to the atmosphere and the brakes become released. At the same time, the feed groove *h* again establishes communication between the train pipe and the auxiliary reservoir, so that compressed air from the main reservoir upon the locomotive passes into and recharges the auxiliary reservoir, so that it is restored to a condition of readiness for again applying the brakes.

An Emergency Discharge.— Should an emergency arise, in which it is important to stop the train quickly, the engineer discharges at once a considerable quantity of air from the train pipe, through his operating valve, thereby rapidly reducing the pressure upon the outer face of the triple-valve piston. This results in such a considerable preponderance of pressure upon the right face of the piston that the movement of the latter toward the left cannot be resisted by the spring supporting the stem *j*. The spring becomes compressed and permits the piston to continue its movement to the left until stopped by reaching the end of the chamber in which it operates. Under such conditions, the slide valve *c* moves so far to the left as to completely uncover the passageway *f* leading to the brake cylinder. A less obstructed discharge of air from the auxiliary reservoir to the brake cylinder results, and the maximum air pressure which can be supplied in the cylinder by the air in the auxiliary reservoir is more quickly attained.

As the automatic air brake is applied by an operation of the triple valve which results from the discharge of air from the train pipe to the atmosphere, it is evident that the application of the brakes need not be confined to the manipulation of the operating valve by the engineer, but will result from any cause by which the train-pipe air pressure may become sufficiently reduced. It was this feature of the apparatus which gave it the designation "automatic." Should any portion of the train become detached, or should the train pipe or hose become ruptured, a reduction of air pressure in the train pipe immediately follows, and the brakes become automatically applied upon all the cars of the train. The importance of this feature of the automatic brake is very marked. Of all the operations of the air-brake apparatus, the necessity of prompt and reliable action, when the full retarding effect of the brakes is needed, stands pre-eminent. Of all the various manipulations of the air pressure, that of permitting the air pressure in the train pipe to be discharged to the atmosphere is the simplest and most surely attainable. In this way, the prompt response of the brake apparatus, when emergency calls for its operation, is most fully assured, and the automatic air brake has therefore taken a most conspicuous place in the front rank of railroad safety appliances. No accidental disorder of the apparatus can prevent the application of the brakes in emergencies. By means of the engineer's operating valve, or of a valve called the conductor's valve, connected with the train pipe in each passenger car, or by the occurrence of any disorder which dissipates the air pressure in the train pipe, the apparatus automatically causes the train to come to a stop — in the latter case calling attention to the disorder and giving opportunity for such repair as shall again insure safety before the train proceeds.

Power Brakes for Freight Trains.— The automatic air brake was very generally adopted for the passenger trains of all important railroads, and fully met all the requirements of its day. When, however, in the development of railroad transportation, the necessity for the use of an automatic power brake upon freight trains became apparent, new conditions were discovered which the automatic air brake was not qualified to meet. During the year 1886, a series of brake trials was conducted at Burlington, Iowa, by a committee of the Master Car Builders' Association, and it was then demonstrated that the operating requirements of power brakes upon long freight trains could not be fulfilled by any power brake in existence. Prompt and efficient as had been the operation of the automatic air brake upon passenger trains, it was discovered that, upon long freight trains, the required reduction of air pressure in the train pipe to actuate the triple valves at the rear end of the train, occupied too long a period of time, when that reduction was effected only by the discharge of the train-pipe air through the engineer's operating valve. The length of the train pipe upon a freight train of 50 cars is about 2,000 feet, or two fifths of a mile. When, in an emergency, the engineer turned the handle of his operating valve so as to permit the compressed air to discharge from the train pipe to the atmosphere as freely as possible, the movement of the air in the train pipe toward the engineer's valve was so resisted and retarded by friction upon the walls of the train pipe that fully 17 seconds elapsed from the time that the discharge began at the engineer's brake valve until the pressure in the train pipe upon the rear cars became sufficiently reduced to cause the triple valve to operate. The brakes upon the forward cars were promptly applied with full force, so that the speed of the forward portion of the train became materially reduced before the brakes began to apply upon the rear portion of the train. In consequence, the cars of the rear portion of the train plunged forward unresisted into those which were retarded by the brakes at the forward end, with a force that almost equaled that of collision. The shocks produced by such collision were sufficient to seriously damage the cars and their lading.

It was clearly evident that the usefulness of the automatic air brake upon freight trains became contingent upon the discovery of some means whereby the interval of time elapsing between the application of the brakes upon the cars of the forward end and those at the rear end of the train, could be so diminished that no damaging shocks should result from any operation of the brakes. An examination of the conditions of operation made it equally evident that but two methods could be utilized for securing a more nearly simultaneous application of the brakes to all the cars, one of which is to reduce the air pressure in the train pipe so gradually that such reduction is nearly uniform throughout the train, and the other is to provide a series of openings in the train pipe, in addition to that through the engineer's brake valve, so that the train-pipe air may be discharged at different points throughout the train, at approximately the same time. While the first of these two methods proves entirely satisfactory for ordinary applications of the brakes in regular service, so much time is occupied by it that it is wholly unsuitable for applying the brakes when emergencies require prompt and efficient action. The second method, therefore, became the only practical solution of the use of the compressed air brake as an effective safety appliance upon freight trains.

The Quick-Action Air Brake.— This invention, introduced by Mr. Westinghouse about the beginning of the year 1888, was the result of

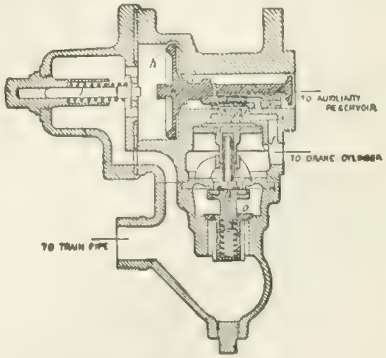

Fig. 3.—Quick-Action Triple Valve.

the development of the principle of venting the train pipe at each car, for quickly applying the brakes. The train pipe is provided with a vent

valve upon each car, which is operated by the mechanism of the triple valve, when, and only when, an emergency application of the brakes is desired. By discharging the air, vented from the train pipe in emergency applications, into the brake cylinder, instead of into the atmosphere, Mr. Westinghouse also discovered that a considerably more powerful and effective application of the brakes could be secured in emergencies than is found to be necessary or desirable for use in the ordinary operations of the brakes in customary service. The mechanism of the quick-action automatic air brake consists of the apparatus hitherto employed in the automatic air-brake system, with the simple addition of the train-pipe vent valve and the means for causing it to operate in emergency applications. A sectional view of the quick-action triple valve is illustrated in Fig. 3.

All of the upper portion of this triple valve is of the same construction as that already described in connection with the automatic air brake, with the single exception that the main slide valve *c* is lengthened at the forward end, and this added portion is supplied with a somewhat restricted port *k*. In all applications of the brakes which result from such moderate reductions of train-pipe air pressure as occur in all ordinary service, this portion of the triple valve is alone operative. The additional quick-action mechanism consists of the supplemental piston *m*, situated in the cylindrical chamber below the slide valve, an emergency valve *n*, with a stem extending upward to the piston, and a check valve *o* directly below the emergency valve. A light spring, situated between the check valve and the emergency valve, serves to support the emergency valve and supplementary piston in the positions shown, under all ordinary circumstances. The port or passageway *p*, indicated by dotted lines, connects the main valve chamber with the chamber above the supplementary piston *m*. This port is normally covered and closed by the slide valve *c*, and is only uncovered when the triple-valve piston *a* moves to the left with sufficient force to compress the supporting spring of the stem *j*, and thereby completes its full traverse to the end of its chamber. When the complete movement of the triple-valve piston thus occurs, the port *p* is uncovered through a notched opening in the lower face of the slide valve *c*, which, however, could not well be illustrated, because of the fact that both it and the dotted port *p* are situated behind the plane of the section shown.

Making a Sudden Stop.— When an emergency occurs, in which the engineer finds it necessary to bring the train to a sudden stop, he moves the handle of the brake valve into a position for quickly discharging the air from the train pipe, whereby a sudden and material reduction of the air pressure is effected in the train pipe upon the first car and in the connected chamber at the left of the triple-valve piston *a*. This results in such a preponderance of air pressure from the auxiliary reservoir upon the right face of the triple-valve piston that the piston is quickly moved to the left, compressing the supporting spring of the stem *j*, until it reaches the end of its chamber. The passageway *p* being thereby uncovered, air pressure from the auxiliary reservoir instantly acts upon the upper face of the supplemental piston *m*, to force it downward and open the emergency valve *n*, as illustrated in Fig. 4.

To clearly comprehend what then takes place, it is important to fully realize the conditions which exist at this instant; they are (1) that no compressed air has as yet, during the practically instantaneous operation above described, entered the brake cylinder from any source; (2) that the compressed air can be discharged from the auxiliary reservoir into the brake cylinder only comparatively slowly, because of the restricted character of the port *k* in the slide valve; and (3) that the air pressure in the train pipe, while having been suddenly and materially reduced below the pressure in the auxiliary reservoir, to the extent of 5 or 10 pounds, or possibly more, is still very considerable (60 or 65 pounds), and it has, by merely lifting the check valve *o*, a capacious and unobstructed passageway, past the open emergency valve *n*, into the as yet empty brake cylinder. In consequence of the existence of these conditions, the check valve *o* is lifted from its seat, against the light resistance of its spring (as indicated in Fig. 4.), and the train-

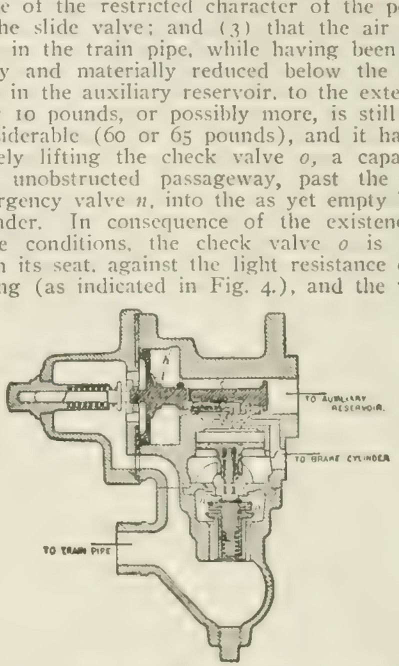

FIG. 4.—Quick-Action Triple Valve, Emergency Valve Open.

pipe air rushes into the brake cylinder, thereby greatly reducing the train-pipe air pressure in the vicinity. When the brake cylinder has become filled with air at the reduced pressure in the train pipe, the spring above the check valve *o* immediately causes it to be closed, cutting off a return of any air from the brake cylinder to the train pipe, as the pressure in the latter becomes further reduced. The air in the auxiliary reservoir, which also has been comparatively slowly discharging into the brake cylinder during the operation just described, now continues to discharge through the port *k* and the passageway *f*, and to add to the contents of the brake cylinder, until equilibrium of pressure exists in the reservoir and brake cylinder.

The sudden discharge of a large quantity of air from the train pipe into the brake cylinder of the first car, not only thus causes a quick and powerful application of the brakes upon that car, but also produces a sudden and material reduction of the air pressure upon the left face of the triple-valve piston *a* upon the second car, thereby reproducing the conditions necessary for the complete movement to the left of the triple-valve piston and a repetition of the operation which occurred in the triple valve of the first car. This operation of the triple valve of the second car similarly actuates the quick-action

triple valve upon the third car, and so on, from car to car, throughout the train. The accomplishment of these successive or serial operations of the triple valves throughout the train occurs with such astonishing rapidity that, whereas 17 seconds elapsed between the application of the old automatic brake upon the first car and the application upon the fiftieth, this interval is but about two and a half seconds in the operation of the quick-action air brake — but little longer than is required for sound to travel through a distance equal to the length of train pipe upon a freight train of 50 cars.

The quick-action automatic air-brake system thus virtually consists of two distinct brake systems — one of moderate power and smooth and gentle application for all the customary operations of every day train service, and the other of high power and violent application for use only when emergencies require most energetic means to avert destruction of life and property. It has practically succeeded all other forms of power brake upon railroad trains, and is now in almost universal use upon the passenger and freight trains in America.

It has already been noted that the condition which determines whether a service or an emergency application of the brakes will result from a reduction of the air pressure in the train pipe, is the rate of rapidity, or the suddenness, with which the reduction of the air pressure in the train pipe takes place. When the air pressure in the train pipe is reduced comparatively slowly, the leftward movement of the triple-valve piston is terminated, by the resistance of the spring supporting the stem *j*, in such a position that the compressed air of the auxiliary reservoir becomes discharged into the brake cylinder, thereby reducing the air pressure of the auxiliary reservoir (which acts upon the right face of the triple-valve piston) co-ordinately with the continued reduction of the air pressure in the train pipe (acting upon the left face of the piston), so that such a preponderance of air pressure upon the right face of the piston, as is necessary to compress the spring of the stem *j*, does not occur. It is only when the air pressure acting upon the left face of the triple-valve piston is reduced much more rapidly than the discharge of auxiliary reservoir air to the brake cylinder will permit the air pressure upon the right face of the piston to be reduced, that the piston makes its complete movement to the left and causes a quick application of the brakes throughout the train. It is necessary, therefore, that the engineer's brake-operating valve shall be provided with such means as shall readily enable the engineer to discharge air from the train pipe with only such rapidity as shall result in a service application, or to discharge the air with such greater rapidity as shall cause the emergency application of the brakes.

It is found also that, inasmuch as it is necessary to elevate the air pressure in the train pipe, as rapidly as possible, to a point somewhat above the pressure of the air remaining in the auxiliary reservoirs after an application of the brakes, in order to force the triple-valve piston to the right and release the brakes, the provision of a stored pressure in the main reservoir upon the locomotive, higher than that ordinarily charged into the train pipe and brake apparatus, is very desirable for temporary use in effecting a prompt release of the brakes. It has thus occurred that the primitive three-way cock, used for an engineer's brake-operating valve in the earlier forms of the air brake, has given place to a more complicated device, now employed for effecting the various operations of the quick-action air brake.

Engineer's Brake Valve.— The functions of the modern engineer's brake valve may be enumerated as follows: To supply air to the train pipe and the auxiliary reservoirs throughout the train, at a certain definitely determined pressure, for the proper operation of the brakes — the standard pressure adopted for this purpose by the railroads being 70 pounds; to discharge air from the train pipe to the atmosphere at such a rate of rapidity that all the applications of the brakes in customary service may be effected without the operation of the quick-action mechanism of the triple valves; to maintain any reduced train-pipe air pressure, resulting from an application of the brakes, so that the brakes may be kept applied with the force corresponding to such reduced train-pipe pressure; to discharge air from the train pipe to the atmosphere with such rapidity, in emergency applications of the brakes, as shall cause the quick-action mechanism of the triple valves to operate with certainty; and to temporarily supply the train pipe with an unusually high air pressure, whenever the brakes

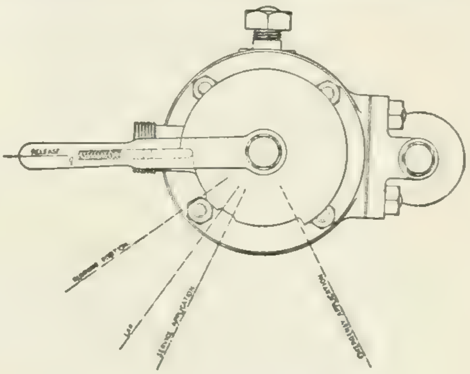

Fig. 5.—Engineer's Brake Valve.

are to be released. These various operations are in practice controlled by different positions of a rotary disk valve, the various positions of which are defined and secured by the movement of a handle operated by the engineer.

In order to avoid confusion, and to more clearly illustrate the construction and operation of the engineer's brake valve, it is somewhat diagrammatically shown, with its ports and passageways so arranged in one plane that a single sectional view of the structure will show them all, except those in the rotary disk valve.

Fig. 5 illustrates a plan view of the valve, showing the handle in the position for releasing the brakes. The other various axial positions of the handle are indicated by dotted lines. Within the handle, there is a latch or pawl, held in position by a coil spring (indicated by dotted lines, and also shown in Fig. 10), which, by engaging with various projections upon a disk, against which the pawl presses, readily indicates to the engineer's sense of touch the various positions of the handle for causing corresponding operations of the brake apparatus.

Fig. 6 illustrates a sectional view of the en-

gineer's valve, with the handle in the running position, in which air from the main reservoir is admitted into the train pipe for the purpose of charging the brake apparatus upon the cars with the proper degree of air pressure. The handle *q* is connected, by means of a spindle, with the rotary disk valve *r*. In the seat upon which the valve *r* rotates, there are shown four passageways. The passageway *e* leads directly to the train pipe; the passageway *z* leads directly to the atmosphere; the passageway *x* leads to the chamber *y* above the piston *u* and the passageway *g* leads to the chamber containing the valve *v*, at the upper end of the structure, called the feed valve. In this feed valve, the small supply valve *u* controls communication between the passageway *g* and a chamber above the piston *t*, which chamber is connected by a passageway *l* with the passageway *e* leading directly to the train pipe. In Fig. 6, the piston *t* and valve *v* are shown in their uppermost positions, being sustained in those positions by the upward pressure of the spring *s*, which upward pressure is properly adjusted by means of the screw plug which supports the lower end of the spring. It is a standard practice upon railroads to charge the train pipe and auxiliary reservoirs upon the cars with air at 70 pounds pressure, and the adjustment of the spring *s* is, therefore, so regulated by the screw plug that an air pressure of 70 pounds per square inch upon the upper face of the piston *t* is necessary to force the piston downward and compress the spring, thereby permitting the valve *v* to be forced to its seat by the light spring pressing upon its upper face.

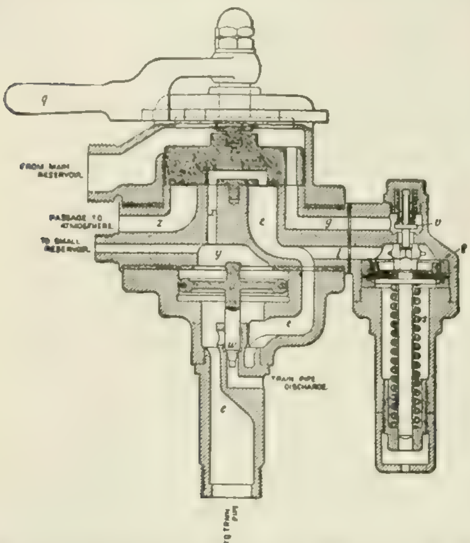

FIG. 6.—Engineer's Brake Valve, Handle in Running Position.

Extending downward from the piston *u*, is a stem which terminates in the poppet valve *w*. The valve *w* normally closes a passageway leading from the train-pipe passageway *e* to the atmosphere. The lower face of the piston *u* is always subject to the air pressure existing in the train pipe, while the upper face is subjected to the variable air pressure in the chamber *y*. Because of the necessarily small volume of the chamber *y*, owing to its position in the midst of a structure which must occupy as small a space as practicable, a passageway leads from it to a small reservoir, which is connected with the structure of the engineer's valve by means of a pipe. In this manner, the chamber *y* becomes a portion of a reservoir or chamber of sufficient volume to permit an accurate reduction of air pressure therein, through the discharge of a portion of the compressed air therefrom to the atmosphere. This small reservoir, which is located in any convenient place, out of the way of the engineer, has, therefore, no other function than to virtually provide such a volume for the chamber *y* as could not otherwise be acquired, without greatly increasing the bulk of the engineer's valve structure, and so rendering it cumbersome and an obstruction in the engineer's cab.

With the handle in the running position, as shown in Fig. 6, the rotary valve *r* is shown in the position in which a passageway through the valve conducts air from the main reservoir to the passageway *g*, leading to the feed valve. The air passes beneath the supply valve *v* into the chamber above the piston *t* and thence by the passageways *l* and *e*, into the train pipe and the auxiliary reservoirs upon the cars. This flow of air from the main reservoir into the train pipe and auxiliary reservoirs continues until they are charged with a pressure of 70 pounds per square inch, whereupon the piston *t* is forced downward, compressing the spring *s* and permitting the supply valve *v* to become seated and cut off further communication between the main reservoir and the train pipe.

The apparatus upon the cars is now charged and ready to apply the brakes, whenever desirable; but the air pump upon the locomotive continues to compress air into the main reservoir, until the latter is charged with an air pressure of about 90 pounds per square inch, at which pressure a pump controlling device, called

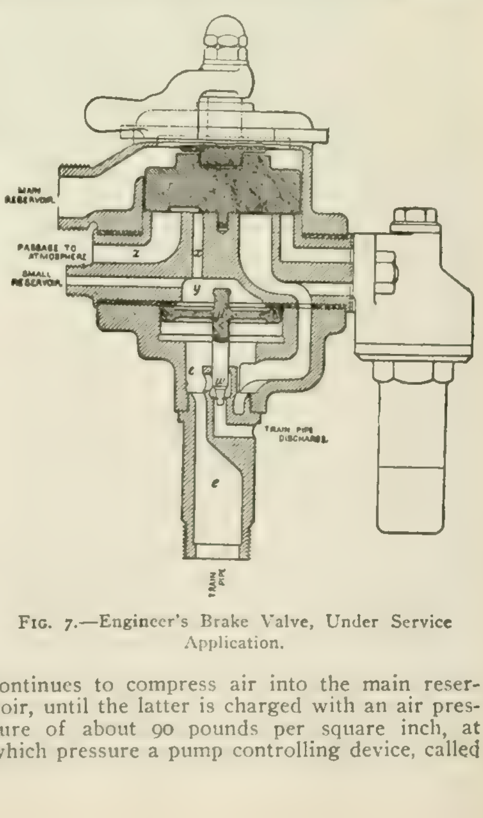

FIG. 7.—Engineer's Brake Valve, Under Service Application.

the pump governor, connected by pipe with the main reservoir, is so caused to operate as to cut off the steam supply to the pump and stop its operation.

It is also to be noted that, in this position of the rotary valve *r*, a passageway is provided which connects the passageways *e* and *x*, so that the chamber *y* and the small reservoir connected therewith are in direct communication with the train pipe and charged with the same air pressure as exists in the train pipe.

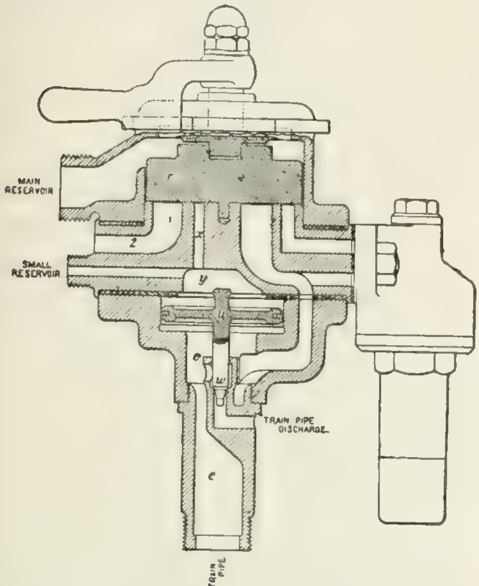

FIG. 8.—Engineer's Brake Valve, Communication Cut Off.

If, while the air-brake apparatus throughout the train is thus charged with the proper air pressure, any reduction of the air pressure should occur through leakage at any part of the apparatus, the effect is to diminish the pressure upon the upper face of piston *t* of the feed valve, thereby permitting the spring *s* to force the piston upward, unseating the supply valve *v*, and so to permit air from the main reservoir to flow into the train pipe and restore the pressure therein, and in the connected auxiliary reservoirs, to 70 pounds. In like manner, a reduction of pressure in the main reservoir, from any cause, acts upon the pump governor to restore the steam supply to the air pump, which replenishes the pressure in the main reservoir and restores it to 90 pounds.

In making a service application of the brakes, the engineer brings his handle into the proper position, thereby moving the rotary valve *r* into a position where the conditions are as illustrated in Fig. 7. In this position of the rotary valve, all communication between the main reservoir and other parts of the apparatus is cut off, and communication between the chamber *y*, above piston *u*, and the train pipe is similarly broken. At the same time, by means of a small cavity in the rotary valve *r*, the passageway *x* is placed in communication with the passageway *z*, so that air from the chamber *y* and the small reservoir connected to it may be discharged into the atmosphere. The immediate effect of reducing the air pressure upon the upper face of piston *u*, while the train-pipe air pressure below the piston remains unchanged, is to cause the piston *u* to be forced upward, thereby unseating the valve *w* and permitting air to be discharged from the train pipe directly to the atmosphere, through the train-pipe discharge passage. The pipe connecting the chamber *y* with the small reservoir is also connected by a branch pipe with an air-pressure gauge, by means of which the engineer is enabled to see how much the air pressure in chamber *y* is reduced by so discharging the air therefrom. When the air pressure in chamber *y* has been reduced to the extent that it is desired to reduce the train-pipe air pressure, the engineer moves his handle into the lap position, thereby bringing the rotary valve into the position illustrated in Fig. 8.

In this position of the rotary valve, all communication between the respective passageways is cut off. The air continues to discharge from the train pipe, through the train-pipe discharge passage, until the air pressure in the train pipe has been reduced to a point slightly below that to which the pressure in the chamber *y* was reduced by discharge of air from the latter chamber to the atmosphere. Thereupon, the preponderance of pressure upon the upper face of piston *u* causes the piston to move downward and reseat the valve *w*, thereby cutting off further discharge of air from the train pipe to the atmosphere. Should the engineer subsequently wish to apply the brakes with a greater force, he again moves the handle of his valve to the position for making service applications and discharges an additional quantity of air from the chamber *y*, to further reduce the air pressure therein. This results in the piston *u* being again

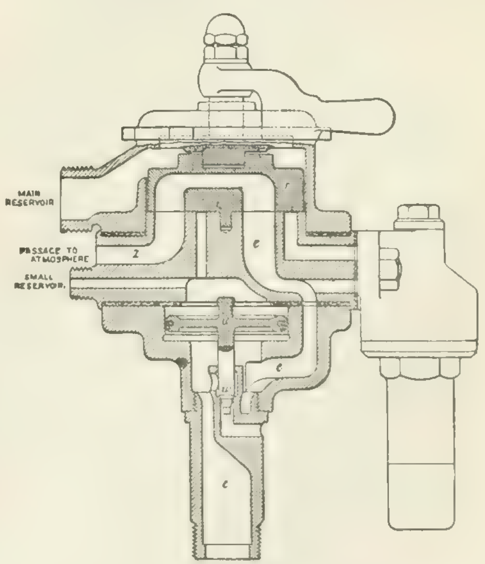

FIG. 9.—Engineer's Brake Valve, Emergency Application.

forced upward, again unseating the valve *w* and further discharging air from the train pipe.

There are two reasons for the interposition of the piston *u* and valve *w*, in this process of

discharging air from the train pipe, instead of discharging it directly to the atmosphere, through a port in the rotary valve *r*, which would appear to be the most natural and simple course. One reason is that, as the number of cars composing a train varies greatly, the length of train pipe of a train of cars likewise varies between wide limits. Upon a short train, the volume of air which must be discharged from the train pipe, to effect a given reduction of air pressure therein, is very much less than the volume which must be discharged from the train pipe of a long train, to produce the same reduction of air pressure. If the air were directly discharged from the train pipe into the atmosphere, therefore, it would be necessary for the engineer to hold the handle of the brake valve

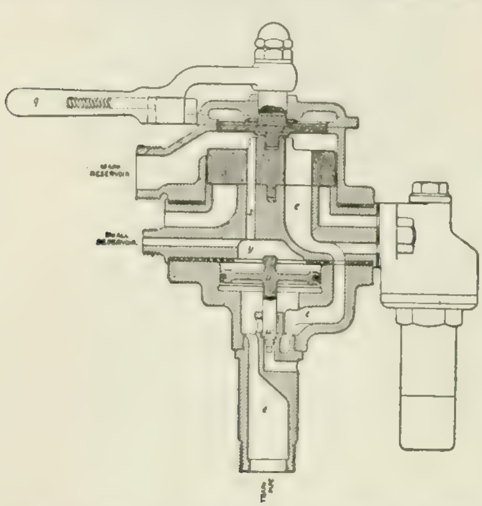

Fig. 10.—Engineer's Brake Valve. Release Position.

in the position for making a service application a different length of time for each different length of train, to cause the same reduction of air pressure; while, with the use of the chamber *y* and connected reservoir, the engineer discharges the same quantity of air therefrom to the atmosphere, upon any length of train, to cause a given reduction of train-pipe air pressure, and the piston *u* remains in its upward position a longer or shorter time, depending upon the length of the train. By this means, the engineer becomes readily accustomed to hold the handle of his brake valve in the service application position the proper length of time to produce any given reduction of train-pipe air pressure, and thus, with experience, he is enabled, with reasonable accuracy, to apply the brakes with the desired force, without the necessity of consulting the pressure gauge.

The other reason for the use of piston *u* and valve *w* is that it is desirable that the discharge of air from the train pipe to the atmosphere shall be gradually and not suddenly terminated. The body of air in the train pipe acquires considerable velocity of movement toward the engineer's brake valve, during the period that the discharge continues, and the sudden termination of such discharge usually results in a temporary increase of pressure at the forward end of the train pipe, sufficient to cause the release of the brakes that have most quickly applied at the forward end of the train. By means of the conical teat below the valve *w*, the downward motion of the piston *u*, which is gradual, is accompanied by a gradual closure of the train-pipe discharge passage, thereby preventing such an increase of air pressure in the forward end of the train pipe, after closure, as would result in causing the release of any of the brakes.

In an emergency application of the brakes, the rotary valve *r* is turned to a position for establishing the conditions illustrated in Fig. 9. By means of a cavity in the rotary valve, the train-pipe passageway *c* is brought into direct communication with the passageway *z*, leading to the atmosphere. The air in the train pipe is thus provided with an unobstructed avenue for discharge to the atmosphere, whereby the train-pipe air pressure is so rapidly reduced as to cause an emergency application of the brakes throughout the train.

To release the brakes, after any kind of an application, the handle of the engineer's brake valve is placed in the release position, in which the rotary valve *r* is brought to a position for effecting the conditions illustrated in Fig. 10. In this position of the rotary valve, communication is established from the main reservoir to the train pipe, through a port leading to the passageway *c*, and to the chamber *y*, by a port leading to the passageway *x*. By this means, the main reservoir air is furnished with an unobstructed passageway to the train pipe, for quickly replenishing the air pressure therein, and the air pressure in the chamber *y* and connected reservoir is simultaneously replenished so as to prevent the increasing train-pipe pressure from lifting the piston *u*. The handle of the engineer's brake valve is customarily left in the release position only long enough to assure the release of all the brakes upon the train when it is turned into the running position, which restores the conditions illustrated in Fig. 6, whereby the train pipe and auxiliary reservoirs are again charged with an air pressure of 70 pounds and are so placed in a condition of readiness for the next application of the brakes.

About the year 1891, the high-speed brake was devised. As long ago as 1876, during some extensive brake trials in England, with apparatus designed and constructed by Mr. Westinghouse and conducted by Capt. Douglas Galton, in behalf of the Institute of Mechanical Engineers of London, it was discovered that the friction between brake shoes and wheels varies greatly at different speeds. The friction of the brake shoes upon the wheels produces a tendency to stop their rotation, while the friction between the rails and the wheels causes the wheels to continue to rotate in spite of the resistance to rotation produced by the brake-shoe friction, and thus the rail friction upon the wheels is what finally and actually retards the motion of the train. In the Westinghouse-Galton brake trials, it was discovered that the rail friction upon the wheels (which is really the friction of rest) is practically the same at all speeds, and the same brake-shoe friction ought therefore to be utilized at all speeds, to produce the best results in stopping. But, as already stated, it was discovered that the friction of the brake shoes continually decreases as higher speeds are attained, and it is therefore very desirable that the brake shoes should be applied to the wheels with

greater pressure at high speed than at low speed, to compensate for the reduced coefficient of friction at the high speeds.

The high-speed brake is designed for the purpose of realizing a greater brake-shoe pressure at high speed, which is subsequently reduced, as the speed of the train declines during the stop, until the pressure has become only such as may be safely maintained until the final stop,

RELEASE.

without sliding the wheels upon the rails, it being a well-known fact that the sliding of wheels upon the rails not only seriously damages the wheels but also very materially increases the distance in which the train can be stopped. The apparatus consists of the ordinary quick-action automatic brake apparatus, with the addition of an automatic pressure-

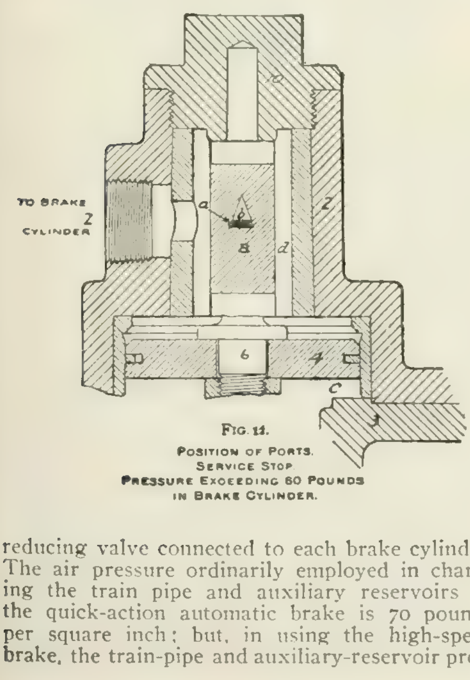

FIG. 12.

SERVICE STOP
PRESSURE EXCEEDING 60 POUNDS
IN BRAKE CYLINDER.

reducing valve connected to each brake cylinder. The air pressure ordinarily employed in charging the train pipe and auxiliary reservoirs of the quick-action automatic brake is 70 pounds per square inch; but, in using the high-speed brake, the train-pipe and auxiliary-reservoir pressure is increased to 110 pounds. In consequence of this increased train-pipe and auxiliary-reservoir pressure, the emergency application of the high-speed brake occurs with a much increased brake-cylinder pressure, which, by means of the automatic reducing valve, is gradually reduced until it becomes only about that which would occur in an emergency application of the ordinary quick-action brake.

It is very important that, in ordinary service applications of the high-speed brake, the brake-cylinder pressure shall not materially exceed that which occurs with the use of the quick-action brake, and it is therefore essential that the automatic reducing valve shall provide such a large release passage for the brake-cylinder air in service applications that the brake-cylinder pressure shall not materially exceed the limit attained with the use of the quick-action brake; but the discharge passage must also be sufficiently small in emergency applications to cause the higher air pressure to accumulate in the brake cylinder and to be discharged only slowly.

These functions of the automatic reducing-valve are obtained by the use of a triangular port opening, the broad base of which exposes

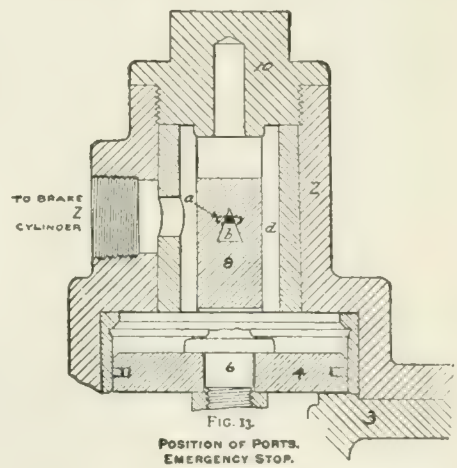

FIG. 13.
POSITION OF PORTS.
EMERGENCY STOP.

a comparatively large opening for releasing any excess pressure in the brake cylinder in service applications, while in emergency applications the valve moves so as to expose the portion near the apex of the triangular port for discharging the air. The arrangement of this port in the reducing valve is illustrated in Figs. 11, 12, and 13, which show the upper portion of the reducing-valve structure. At Z, a pipe connects the reducing valve to the brake cylinder. The piston 4 is thus subjected, upon its upper face, to the air pressure from the brake cylinder, while it is supported at its lower face by a spring, adjusted to hold the piston 4, and the valve 8 attached to it, in the positions shown in Fig. 11, when the brake-cylinder pressure does not exceed that desired in service applications. The slide valve 8 is supplied with the triangular port *b* which, when the pressure in the brake cylinder is less than that for which the spring is adjusted, is in the position shown in Fig. 11, the discharge port *a* in the casing being covered by the slide valve, so that no air

can escape from the brake cylinder. In a service application of the brakes, the brake-cylinder pressure can only comparatively slowly exceed the limit for which the reducing valve is adjusted, and the piston 4 is thereby slowly depressed until the base of the triangular port *b* registers with the discharge port *a*, as shown in Fig 12. In this position of the slide valve, the excess of air in the brake cylinder is rapidly discharged, and the air pressure is thus permitted to but very slightly exceed the limit for which the reducing valve is adjusted.

In an emergency application of the brakes, however, the air pressure in the brake cylinder increases with much greater rapidity than in service applications, and the accumulation of pressure upon the piston 4 causes it to move down more rapidly, bringing the triangular port *b* of the slide valve to register near its apex with the release port *a*, as shown in Fig. 13. In this position of the slide valve 8, the air discharges from the brake cylinder comparatively slowly and the pressure is thus gradually reduced, the piston 4 gradually rising with the reduced pressure, until the pressure has finally become reduced to the limit for which the device is adjusted, when the port *a* is closed and the air pressure then remaining in the brake cylinder continues effective until the train is stopped or the brakes have been released in the customary way by the engineer.

The high-speed brake is now quite generally employed upon the fast passenger trains throughout the United States, and stops trains from speeds of about 60 miles an hour in about 30 per cent shorter distance than the ordinary quick-action air brake.

R. A. Parke,
Expert for Westinghouse Company.

Air-cells, cavities in the cellular tissue of the stems and leaves of plants which contain air only, the juices of the plants being contained in separate vessels. They are largest and most numerous in aquatic plants, as in the *Vallisneria spiralis* and the *Victoria regia,* the gigantic leaves of which latter are buoyed up on the surface of the water by their means. There are also air-cells in the bodies of birds. They are connected with the respiratory system, and are situated in the cavity of the thorax and abdomen, and sometimes extend into the bones. They are most fully developed in birds of powerful and rapid flight, such as the albatross.

Air-chamber, a reservoir in a hydraulic apparatus, in free communication with the water. The chamber or reservoir is filled with air, which by its elasticity diminishes the shocks that would otherwise be produced by sudden changes in the speed of flow of the water, and also equalizes the flow. When the pressure in the pipes is momentarily greater than the normal pressure, water enters the air-chamber and compresses the air it contains; and when the pressure is momentarily less than the normal, the reverse action takes place, and the elasticity of the air forces water back into the pipes.

Air-cock, a cock placed upon a water- or steam-pipe (notably upon a steam radiator) to allow of the escape of air from the piping.

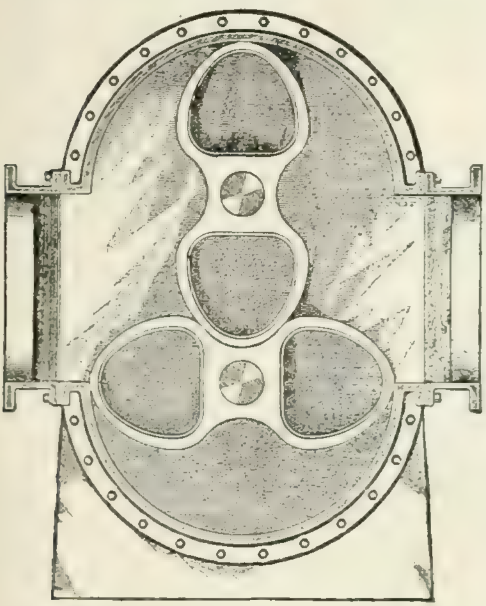
Air-compressors. The various practical applications of compressed air cover a range of pressure from a fraction of an ounce to several thousand pounds per square inch. To produce the required supply of air with proper pressure and economy, numerous types of compressors, each having its peculiar and appropriate field, have been designed. These are, in the order of the pressure produced: the disc fan, the centrifugal blower, the positive blower, the blowing engine, the direct-acting compressor, and the compressor with crank and flywheel. By the operation of all these, the same result is produced — the delivery of a quantity of air under an increased pressure and correspondingly increased temperature, and the subsequent rapid loss by the air of its excess of temperature, with a proportionate decrease in volume. Most of the problems in the design of compressors are created by the heating of the air during compression and by the effects so produced upon the apparatus.

Disc Wheel.

The Disc Fan.—The disc fan, corresponding to the marine screw propeller in action, is useful for producing a flow of air of considerable volume but with almost inappreciable increase of pressure. It is thus suitable for purposes of ventilation in expelling foul air, gases, or smoke, or for removing dust, fine shavings, and waste particles from woodworking and grinding machines. The power expended in revolving the fan goes in great part toward whirling the air current around in the fan casing and pipe — a waste of effort which limits the application of this device to conditions of moderate speed and very light pressure.

The Centrifugal Blower.—By taking advantage of the tendency of revolving particles to fly away at a tangent, a fan blower of better efficiency and a wider field of usefulness is afforded. Particles of air whirled around by the blades of the disc fan merely fly out and press against the casing; but the centrifugal blower converts this action into useful compression through the provision of a spiral casing around the fan, in which the air whirled off by the blades of the fan is deflected and conducted into a discharge pipe leading off from the casing. The blower therefore consists of a fan with radial or sometimes curved blades which stand parallel to the axis instead of obliquely as in the case of the disc fan, and which revolve

in a circular or spiral casing surrounding the fan and opening into a large discharge pipe that leads off at a tangent in any desired direction — up, down, or sideways. Air enters around the shaft of the fan through openings in the centre of the casing, and, being received by the blades, is whirled around and thrown outward into the surrounding chamber with a pressure proportional to the square of the speed of the fan. The pressure thus produced is sufficient for blowing fires of all kinds, for removing small fragments of wood as well as finer particles from wood-cutting machines, for delivering illuminating gas to holders, and for other purposes requiring a pressure of not much over one pound per square inch. The centrifugal blower is the most efficient contrivance known for producing pressures of a few ounces, but its economy falls off very fast if the speed is increased so as to produce pressure as high as one pound per square inch.



Cross-section of Positive Pressure Blower.

This machine seems peculiar in its behavior owing to the fact that it requires less power to maintain a certain speed when the discharge passage is partly closed than when it is fully open. It is evident that when there is no discharge opening, the fan, together with the air between its blades, will spin around freely like any wheel. If the discharge gate be opened, air will flow about the fan blades to their outer ends, and so into the casing and thence to the pipe system; while air from the centre of the fan follows out into the space between the blades, its speed increasing as it approaches the ends of the blades, where it is hurled into the casing. It is the work done in accelerating the motion of these particles of air, which explains the resistance to the movement of the fan; and this work is evidently in proportion to the quantity of air that passes along the fan blades, being zero when, by reason of the closing of either suction or discharge opening, no air is discharged, and being greatest when, with full opening, the volume of air passing is the maximum. The blades of the blower would fly in pieces before the speed could be increased sufficiently to produce an air pressure much over one pound per square inch.

An apparatus identical in principle is the centrifugal pump, which, handling far heavier fluids, produces by centrifugal action pressures measured by pounds instead of ounces.

The Positive Blower.—In direct competition with the centrifugal fan is the positive blower. Consider a fan having opposite blades, revolving in a closed casing, and carrying around with it the air confined between the blades. If a radial partition could be slipped in just after one of the blades had passed, the following blade would compress the air between it and the partition, and would force it out through a discharge pipe if one were provided near the supposed partition. This partition might be imagined to be momentarily withdrawn as each blade passed, so that successive portions of air would be trapped and compressed. The positive blower consists of a fan of this sort, with one or more blades, revolving in connection with an "abutment" performing the office of the partition just alluded to. A well-known form consists of a cylinder carrying two radial blades, and revolving in contact with a cylinder of half the diameter which is provided with a gap of proper form to receive the passing blades. As each blade travels around the casing, it drives the air before it up to the smaller cylinder, whose gap comes around at the proper instant to allow the blade to pass, while intercepting the air continuously. Another type consists of two similar two-leaved cams meshing together like gears, as shown in the sectional illustration.

The positive blower is necessarily made of cast-iron on account of the peculiar shapes required, and its parts are therefore unduly heavy in comparison with their work of compressing air to low pressures. The limit of pressure is not far above that of the centrifugal blower; but as the quantity of air delivered per revolution is practically constant (except for slight leakage), this machine possesses, for certain purposes, some advantages. It is much used for blowing foundry cupolas, moving illuminating gas in gas-works, and for pneumatic-tube transportation.

The Air-compressing Engine.—The air-compressor proper is a cylinder-and-piston machine like the common steam engine. It comprises two sets of valves, usually designed to be opened automatically by excess of pressure under them and to be closed by gravity or by the actions of springs when the pressures become equal. The inlet valves open just after the piston commences its stroke, when the expansion of the compressed air remaining in the cylinder behind the piston has lowered the pressure above the valves. They close at the end of the intake stroke, just as the piston comes to rest. The outlet valves lift during the compression stroke, at about the time the rising pressure in the cylinder becomes equal to that in the outlet passage above the valves; and they close when the flow of air ceases as the piston completes its stroke.

Perfectly correct action of automatic valves is not realized in practice. The valve must

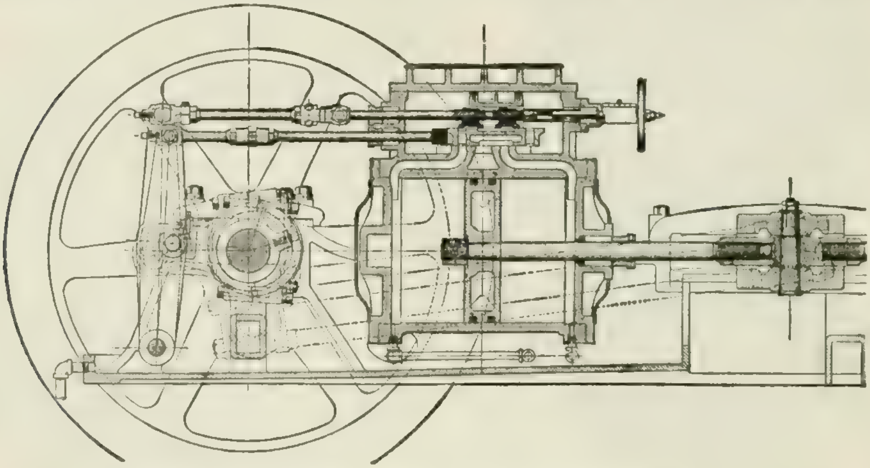
evidently be larger than the opening in its seat, so that the upper surface is larger than the area underneath reached by the lower pressure; consequently the valve will not open until the pressure below is greater than that above. To prevent destructive slamming of the valves, springs must be provided to force them to their seats just as the flow ceases and before the reverse stroke of the piston can cause much backward flow of air. The pressure of the spring acts to choke the flow through the valves, increasing the resistance they offer to the passage of air. Large compressors are therefore often provided with mechanically-actuated valves which are opened and closed smoothly at the proper moment by eccentrics and valve rods. Any of the steam-engine valve gears may be used for compressors, and designed by the same methods, observing only that the compressor is in every way a reversed steam engine, so that its discharge port and valves are duplicates of the inlet details of the engine, while the engine exhaust and the compressor inlet valves are also similarly related.

Varying initial (or boiler) pressure is compensated, except in throttling engines, by varying time of inlet-valve closure or "cut-off"; and varying discharge pressure in a compressor calls for variation in time of opening of the discharge valves. In both cases, the means of variation constitute the chief problem for the designer.

Mechanically-moved inlet valves of compressors act always at the same points, opening a trifle after the piston starts on the intake stroke, and closing exactly at the end of the same stroke; but the discharge valves must open at the instant the piston has compressed the air in front of it to a pressure equaling that above the valves in the discharge pipe, and must close always at the same instant, at the end of the stroke. As the compressor may be working against a pressure greater or less than that regularly carried, the discharge valves must be so controlled as to open at whatever point is required by the pressure then being carried. The requirements are sometimes met by putting automatic lift-valves above, or even directly upon, the mechanical discharge valves, giving the combination the effect of valves automatic as regards their opening, but positively closed by the mechanism at the proper instant. Such lift-valves, being shut off entirely at the proper closing instant, seat themselves without noise or shock, and may therefore have very light springs, causing less resistance to the air passing through.

Where the expense of full mechanical action is warranted on account of the superior efficiency obtainable, poppet or rotary valves may be arranged to open by means of springs or air dashpots. The opening device is released either through the rising pressure in the cylinder easing the valve on its seat, and reducing the friction until the valve, when balanced, slips freely open; or through the same pressure acting on a piston attached to a pusher, the operation of which results either in starting the valve in spite of friction or in lifting a catch and thereby freeing the spring or dashpot mechanism of the compressor.

Compound Compressors.—While low compression pressures are accompanied by only moderate heating of the air during compression, the production of high pressures is attended with excessive heat and considerable increase in the volume of the compressed air. As the air leaving the cylinder soon resumes the normal temperature, and decreases in volume accordingly, the extra work done in compressing the increased volume is wasted. Compressing cylinders in operation are always cooled by water or otherwise; but it is impossible, even by spraying water into the cylinder, to keep the air from rising considerably in temperature. For high pressures, resort is therefore had to compound compression, the air being passed successively through larger low-pressure to smaller high-pressure cylinders, between which are located inter-coolers whose function is to restore the air to its original temperature before it enters on the next stage. The volume of the air is thus kept as small as possible; and the successive stages of compression result in producing the required pressure with a minimum of loss from heating during the process. Two-stage machines are preferred to single-stage where air must be compressed to one sixth or



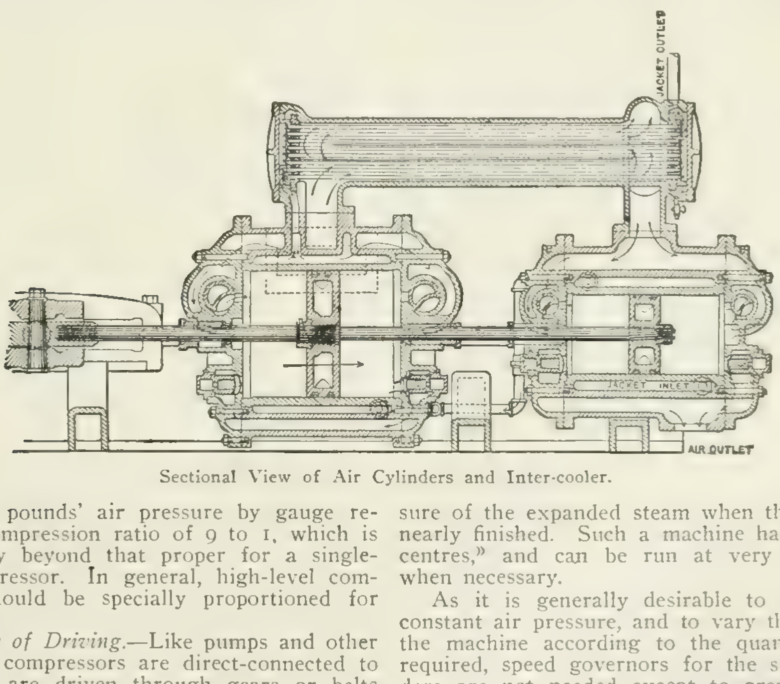
Sectional View of Steam Cylinder of a Typical Air-compressor.

a smaller fraction of its volume at atmospheric pressure (measuring pressures from absolute vacuum); and three or more stages are required in compressing to one sixteenth or less. Cylinder diameters are selected which will provide for about the same amount of work being done in each cylinder.

Most compressor problems deal with air taken directly from the atmosphere at its sea-level pressure; but, as at moderate elevation there is a marked decrease of the atmospheric pressure, compressors for high locations must deal with air at pressures below 15 pounds absolute. Under such conditions the volume of air taken into the compressor at each stroke weighs less, and therefore less air is delivered by the compressor, while there is a corresponding decrease in the power to run the machine. The ratio of compression, and the rise in temperature, are proportionately increased, so that a two-stage compressor may be desirable for pressures that would call for only single cylinders at sea-level. Thus, at many of the mines in the Rocky Mountain region, the atmospheric pressure is as low as 11 pounds per square inch, so that 90 pounds' air pressure by gauge requires a compression ratio of 9 to 1, which is considerably beyond that proper for a single-stage compressor. In general, high-level compressors should be specially proportioned for their work.

Methods of Driving.—Like pumps and other machinery, compressors are direct-connected to engines or are driven through gears or belts from separate sources of power. The reciprocating piston compressor requires a varying effort to balance the cylinder pressure, since, during the stroke, the piston moves against an increasing air pressure, and finally against the full discharge pressure, in pushing out the contents of the cylinder. Direct-connected compressors are either "straight-line" (tandem), having steam and air pistons on the same piston rod, or they are connected to cranks set at an angle on a common shaft. The first method reduces floor space and cost, but requires very heavy fly wheels, and makes the machine liable to stop on a centre if run much below full speed and capacity.

It is evident that steam used expansively supplies against the piston a force decreasing toward the end of the stroke, while air during compression opposes a force increasing toward the end of the stroke; thus the power rapidly falls off as the resistance increases, causing a perceptible reduction in speed at the end of each stroke. If such a machine could be run at high speed, the weight (or more correctly, the mass) of the pistons and connections would, by inertia, help out the decreasing steam pressure when slowing to pass the centres, and thus produce a more even effort on the crank; but sufficiently high speeds are not possible for the automatic-lift valves generally used on small compressors. The varying power and resistance can be very satisfactorily balanced by connecting steam and compressing pistons to separate cranks set at right angles. Having provided two frames and cranks, a slight additional outlay will supply an extra pair of cylinders tandem to the first pair, making a full duplex compressor. The excess steam pressure at the commencement of the stroke of one side is here transmitted by the crank shaft to the other side of the machine, to help out the deficient pressure of the expanded steam when the stroke is nearly finished. Such a machine has no "dead centres," and can be run at very low speed when necessary.



Sectional View of Air Cylinders and Inter-cooler.

As it is generally desirable to maintain a constant air pressure, and to vary the speed of the machine according to the quantity of air required, speed governors for the steam cylinders are not needed except to prevent racing in case of a bursting pipe or other excessive discharge of air. Some form of adjustable cut-off valves is very desirable in order to allow of suiting the work of the steam cylinder to the load. The pressure is controlled by automatic devices actuated by the rise and fall of the air pressure, either shutting off the air intake, opening a by-pass around the compressor piston, or (in case of duplex machines which can start from rest without attention) shutting off steam and stopping the machine.

A description of the standard types of commercial compressors would be incomplete without reference to the most remarkably wasteful "steam eater" known to the compressor trade—a machine using ten times as much steam as

would be necessary for pumping the same amount of air by means of a fairly economical compressor, and yet a device most ingenious and entirely satisfactory for its work. This is the air-brake pump, which, for actual conditions of train service — where it stands idle until the closing of the throttle, and the application of brakes leave a large and heavily fired steam boiler to blow off at the safety valve until the fire can be checked — is seen to be well adapted. Indicator cards show that the entering steam is throttled through about half the stroke, while the exhaust is similarly choked at first and only let out freely about the time of full opening of the valve. The result is a "straight-line" compressor having no crank or flywheel, with nothing moving but its two pistons and one rod, and yet so perfectly balanced between effort and resistance that its strokes are smoothly made at any speed from slowest to fastest, and all with maximum simplicity and minimum weight. These machines are also built with compound steam and two-stage air cylinders, and in these cases have pressures in the cylinders so nearly uniform that the steam distribution may be considerably more economical than it is possible to obtain in the single-stage compressor. See COMPRESSED AIR.

S. H. BUNNELL,
Works Manager, Watertown Engine Company, Watertown, N. Y.

Air Compressors. An air compressor is a device used for compressing air. In itself air lacks the power to do work and serves only as a storer and transmitter of energy. Coal, on the other hand, is a hydro-carbon compound, each element possessing the power to do work when burning. To free the coal of its potential energy it is necessary to apply sufficient heat to begin the operation of burning, and when once started it will continue to give off heat as long as sufficient coal and a sufficient quantity of oxygen are supplied. The burning of coal and the giving up of energy in the form of heat are attended by chemical changes, or changes in the state of matter itself. When air is compressed it has the power to do work by expansion, and as air is expanded the changes in the condition of the air are purely mechanical. Any device which reduces the volume of air with a pressure increase is an air compressor. Air compressors are of two distinct kinds, dry and wet. In the former type a solid piston serves to reduce the volume of air, and in the latter a liquid, usually water, is employed.

Dry or Piston Type.— This is the common form of compressor employed to-day and is widely and extensively used. It consists essentially of a solid shell or cylinder furnished with suitable valves for the admission and discharge of air, and a piston to effect the desired compression. On one stroke of the piston, air is sucked into the cylinder through the inlet valves and when the piston reaches the end of its stroke these valves close just before the piston begins the return stroke. On the return stroke the entrapped air is diminished more and more in volume, with an increase in pressure (and temperature, if compression is not isothermal). At a certain point in the stroke, when a predetermined pressure is reached, the discharge valves open and the compressed air for the remainder of the travel of the piston is forced through the valves into a receiver. When all the air is discharged from the cylinder and the piston begins the return stroke, the discharge valves close and the intake valves again open. Such is, in brief, the operation of an air compressor.

The commercial compressor, however, includes many schemes and modifications to effect the greatest compression with a minimum expenditure of work and trouble. In the practical compressor, the details which receive special attention are main frame, main bearings, air cylinders, air heads, air valves, flywheel, main shaft, crank pins, connecting rod, crosshead, pistons, piston rod, oiling system, bearings, foundation, accessibility, intercooler, governing devices, method of drive, etc. For discussions on these various items, reference should be made to text-books on the subject.

The type of compressor, whether straight line or duplex, single or compound, steam or power driven, depends upon the requirements and natural resources. Following, these points are considered in brief:

Straight Line Compressor.— The straight line compressor is designed to take stresses and strains in direct lines. These machines were originally evolved to meet the demands for compressors which may be easily transported in mountainous countries for distant prospect work, shaft sinking and tunneling operations. Obviously, such service is, almost without exception, hard and continuous. This suggests the question of accessibility and ease in making repairs when no shop facilities are available. The straight line design provides well for all these requirements. Every part of the machine is accessible and an occasional oiling is usually the only attention that such a machine demands. The machine has also been commonly installed in railroad shops for signal work and the like, where absolute reliability in the delivery of compressed air is imperative. For quarrying and also for general contract work this type finds favor. The best straight line machines are built on the lines which a long experience has proved to be the best, that is, power and resistance in straight lines, positive movement of air valves, cold intake air, cooling by a complete surface jacketing, resulting in dry air and effective cylinder lubrication, adjustable steam cut-off for the economical use of steam, small clearance space, automatic speed and air pressure regulation, medium stroke, high rotative speed, extra heavy bearing surfaces for crank pins, shaft and slides, and automatic lubrication. This type of compressor is self-contained and does not require an expensive foundation.

Duplex Air Compressors.— The peculiar requirements of air compressing work are met with in the duplex machine in a manner different from that in the other type just described. In compressing air by means of a reciprocating steam engine the resistance throughout the stroke, due to compression, is inversely proportional to the power in the steam end, that is, at the beginning of compression the pressure is greatest in the steam cylinder and diminishes as the stroke advances, due to expansion of the steam; while the air pressure starts at atmosphere and increases, due to compression.

To equalize resistance and power, no design offers a better solution than the duplex type.

The respective pistons on one side are so adapted, relative to the pistons on the other side, that when one piston is at the beginning of its stroke the other is at the middle of its stroke, whereby the resistance of the air on both pistons is practically equalized throughout the entire stroke.

When steam is the driving fluid, the range of adaptability of the duplex compressor admits of any combinations of duplex or compound steam and air cylinders. The duplex form of construction admits also of installing one side, or the first half, as a compressor complete in itself at a time when the free-air requirement is only one-half of the ultimate demand; the other half may follow later.

Sectional Compressors.— In mountainous regions and in places inaccessible by good roads, where mule-back transportation is the only available means of conveyance, the sectional compressor is employed. Such a machine is so designed that no one section exceeds a given weight limit or proper mule load.

Portable Compressors.— In structural operations where the only air power needed is for driving small machines for operations of a light character and of a shifting nature, the portable compressor outfit possesess many decided advantages. Drilling, chipping and riveting in bridge, railroad, trestle and allied undertakings call for a moderate air supply. It is apparent that the seat of operation is ever changing and that much territory must be covered as the work progresses. The portable compressor is especially adapted for such work. A portable outfit is a complete plant in itself, having boiler, engine, compressor, receiver and the necessary appurtenances mounted on one truck. The plant may be drawn by two or more horses.

Single and Multiple Stage Compression.— Air is compressed in single, two or more stages, depending upon the degrees of compression required. The practical limiting pressure to which to compress air economically in a single stage is about 70 pounds per square inch gauge. Above this point two, three or more stages are employed. Single stage compressors were the earlier forms of machines designed, and are still extensively used for purposes not demanding more than about 70 to 80 pounds pressure. Such machines are used for supplying air to drills, pneumatic tools and the like.

Compound compressors have many advantages over single stage machines. The efficiency, owing to the heat of compression, decreases as the terminal pressure increases, and for pressures above 70 pounds the water jacket of the simple compressor is not sufficiently effective for producing the most economical results; and stage or compound compression is resorted to as the most practical and efficient method for reducing the loss due to the heat of compression. In the compound compressor the cylinder diameters are so proportioned as to divide the work of compression equally between a given number of cylinders. All air cylinders are provided with water jackets and are connected by intercoolers. Free air is admitted to the low pressure cylinder, where it is partially compressed and then forced into the intercooler. The intercooler acts as a receiver and at the same time removes the heat of compression of the intake cylinder before the air is admitted to the second stage cylinder. In the high pressure cylinder (in a two stage machine) the process of compression is completed and the air is delivered to the receiver at the required terminal pressure. The final temperature in each cylinder would be the same if the work was divided equally and the intercooler properly designed, but it will be very much lower than if the compression were done in one cylinder.

To illustrate the difference in effect between single, two or three stage compression, let us take a specific case. Let it be required to compress one cubic foot of free sea level air to 200 pounds gauge pressure, assuming the intake air to be 60° F., and the intercooler process perfect; the ideal or isothermal compression requires 0.1719 horse-power to do the work. The actual or adiabatic work demanded is 0.26 horse-power for single, 0.21 horse-power for two stage, and 0.196 horse-power for three stage compression. Compressing the air adiabatically to 200 pounds gauge pressure in a single stage necessitates a loss of 51.2 per cent. Two and three stage compression occasion losses of 22.2 per cent and 14.0 per cent respectively. The temperature of the air in one stage and at 200 pounds pressure reaches 673° F., while for two and three stage operations 308° F. and 213° F. are the maximum temperatures. The excessive loss in work and the extreme temperature reached in single compression for so high a terminal pressure demand the employment of a compound two or three stage compressor. As mentioned above, for single stage compression 70 pounds gauge is about the limiting economical pressure. The temperature reached in compressing in a single stage to 70 pounds gauge is about 404° F.

The principal advantage of compound compression over simple compression lies in the reduction of the loss due to the heat of compression, which represents, therefore, a saving in power, since the resistance due to compression is directly proportional to changes in temperature.

Intercoolers.— An intercooler is a device used for cooling the air between stages in a compound compressor. It consists essentially of a shell or casing filled with nests of galvanized iron or brass tubes through which cooling water circulates. Baffle plates are provided so that the air passing through the tubes is so distributed with reference to the cooling surface of the pipes that it readily parts with its heat to the cooling water.

The great advantage of compounding is due very largely to the use of intercoolers, and this advantage depends upon the fact that more time is taken to compress a certain volume of air, and that this air during the stages of compression is brought in contact with an efficient cooler. A properly designed intercooler should reduce the temperature of the air back to the original point, that is, to the temperature of the intake air, and even lower if the water is cold enough. The tubes of the intercooler should be placed close enough together that the air when passing through must be split up into thin sheets. These devices are naturally expensive, but first cost is of small moment when compared with the efficiency of the compressor and its effect upon the coal and water consumed.

Steam Driven Compressors.— The air compressors in operation to-day are largely of the steam driven variety, both of the straight line and duplex types. The duplex steam driven machine represents probably the best form of compressor for plants of large size and permanent character. As the economy of a compressor is to a large extent dependent upon the efficiency and economy of the engine to which it is attached, this part of the machine has received special attention and has been developed to the highest point. Three methods of controlling steam admission to the steam cylinders are through slide valves, Meyer adjustable cut-off valves, and Corliss valves. The slide valves are used only on machines of comparatively small capacity and moderate cost, the Meyer on larger and more costly compressors, and the Corliss valves on the largest and most economical machines.

Simple and Compound Steam Cylinders.— Simple steam cylinders are used in installations where the matter of economy in steam consumption is not paramount. Such cylinders are used for steam not over a pressure of about 75 or 80 pounds. In machines demanding the greatest economy and where the steam pressure is high, compound machines are resorted to. Steam is admitted first into the high pressure cylinder where it expands and does work; it is then exhausted into a steam receiver and thence into the second cylinder for further work.

Power Driven Compressors.— The usual conditions under which an air compressor is installed are such as to favor one that is driven independently of any other machinery. Still there are many cases where the independent steam actuated compressor is replaced to advantage with a machine driven from some outside source of power. For instance, from a line shaft by gearing, belt, chain or ropes, from an electric motor, from a gas or oil engine or from an impulse, turbine or other water wheel. In some of these compressors the driving pulley or water wheel is on the main shaft and in others a countershaft is used to advantage, the ratio given frequently being two to one, but generally decided by the peculiarities of each separate case. When sufficient water power is available within several miles of the plant where power is used, this energy may be utilized for compressing air to be piped to the works and there used with great success and economy for pumping, hoisting, drilling and many other purposes. In some few cases power may be converted into electrical energy to advantage, the current so generated being used for driving a number of compressors located close to the seat of operations for driving pneumatic machinery.

Power-driven compressors may be of the simple straight line type or of duplex construction, furnished with single or double acting cylinders. The simple straight line form may be used where the demand for air is light. This machine has the same advantage as the steam-driven straight line machine, in that it takes up stresses and strains in direct lines. Duplex machines are largely for service where the demand for air is considerable. Such machines have the advantage of relieving many of the excessive strains to which the compressor may be subjected by dividing the work equally between the cylinders and counterbalancing impulses. These machines are made with either simple or compound air cylinders, the former being used for sand blast work and the like, where the pressure in no case exceeds the economical limit of 70 pounds. Above this pressure compound cylinders are employed and are provided with a suitable intercooler to remove the heat of compression as the air passes from the low to the high pressure cylinder. The air cylinders are water jacketed, that the valves and moving parts may be kept cool to assist the machine in its proper performance.

The modern power driven compressor driven by gears, by a silent chain, or direct connected to an electric motor or gas engine, operates with efficiency and reliability. The belt driven compressor may be run from a countershaft or from an electric motor, oil or gasoline engine. The gear driven compressor is especially convenient for connecting to an electric motor. The chain driven compressor is built for connection with any kind of motor. Its construction admits of a minimum distance between motor and compressor shaft, so that the least possible space is taken up by the complete machine. The power used for running the belt machine, of course, depends upon conditions. Where there is an existing line shaft driven by a shop engine with surplus power, the best method of drive would probably be a belt, or if the cramped floor space prevents adequate belt centres a rope drive may be preferable, the driving wheel of the compressor being grooved instead of crowned. Again where water power is available a water motor may be used, the conditions of head and quantity of water determining the speed and thus regulating the use of a belt, chain or direct connection. Where the line shafts are not available, the compressor may be operated to advantage from either a gas engine or an electric motor. The selection of either one or the other of these types of machines depends upon the availability of either gas or electrical energy.

Wet or Hydraulic Types of Compressors.— There are three distinct varieties of wet compressors: First, where power is generated by the falling of water; second, where the power is mechanical, ultimately driving a water piston; third, the type in which cooling water is injected directly into the cylinder.

The first is used where there is an abundant water fall and where a high efficiency is not required. The second has the advantage of eliminating entirely the undesirable clearance, as the water used in this instance fills all the dead space not reached by a solid piston. Piston speed is of necessity limited to a low rate due to the mass of water to be moved. As a result, if a large quantity of compressed air is required a multiplicity of compressors must be used. The third is desirable from the point of excellent cooling, but as the fluid used is a poor lubricant, proper lubrication is interfered with which results in a loss of power and increased wear. This variety also has the decided disadvantage of causing compressed air to become very moist, and unless reheating is resorted to before the air is applied to useful purposes it will cause difficulty in cold weather due to freezing. For a more detailed description of hydraulic compressors, reference will

be made to literature on the subject. As a matter of fact, the hydraulic compressor is rarely used, as it is largely impracticable due to lack of efficiency and mainly on account of its cumberousness.

Air Distribution or Transmission.— After the air is compressed it must be properly stored and conveyed and applied to secure all the benefits. For this purpose the aftercooler is important as it serves to reduce the temperature of the air after the final compression, and in doing this it serves as a drier, reducing the temperature to the dew point, thus precipitating moisture before the air is started on its journey. Other important appliances in distribution are receivers, which serve the purpose of reservoir, watertrap and rectifier; pipe lines, for transmitting compressed air from the compressor to the points of application, and reheaters, for heating the air close to the point of admission to the motor.

Application of Compressed Air.— At the present time compressed air is used in almost every art known to man. Its safety, the ease with which it is transported, its simplicity, its applicability to common engines and its use for many different purposes, its economy and the great service it renders in ventilation and cooling are reasons why compressed air is used so extensively. Some of the more important applications of compressed air are for ventilation and heating, air motors, rock drills, quarrying machines, pumps, pneumatic haulage, pneumatic dispatch tubes, pneumatic tools, air jacks, air hoists, air cleaning, etc. See COMPRESSED AIR; PUMPS, COMPRESSED AIR.

EDWARD F. SCHAEFER, M.M.E.,
Ingersoll-Rand Company, New York.

Aird, Thomas, a Scotch poet who has won praise from high critics, but little popular acceptance: b. Roxburghshire, 1802; d. 25 April 1876. He studied in the University of Edinburgh, and formed a lifelong intimacy with Carlyle; contributed to 'Blackwood's,' and won the warm good will of Wilson; edited the *Weekly Journal* 1832–5, and the *Dumfriesshire and Galloway Herald* (Dumfries) 1835–64. He published 'Religious Characteristics,' prose essays (1827); 'The Captive of Fez,' narrative poem (1830); a character story, 'The Old Bachelor in the Scottish Village' (1845), very popular at the time; etc. But he is best (or at all) remembered now for his 'Devil's Dream.'

Airdrie, a municipal and parliamentary burgh, Scotland, in Lanarkshire, 11 m. E. of Glasgow. It depends chiefly on the collieries and iron-works in its vicinity, but has also a large cotton-mill and factory, several extensive foundries and machine-shops, tube-works, and a number of hand-loom weavers. Pop. (1901) 22,288.

Air-drill, a rock drill or other form of drill actuated by compressed air.

Airedale Dog. See TERRIER.

Air-engine, an engine in which air is the working body. Such an engine may be operated by air previously raised to a high pressure by a compressor, as in the storage and transmission of power by compressed air; or it may derive its power directly from the burning of fuel. In the latter case it is often called a hot-air engine. (For the elementary theory of the hot-air engine, see THERMODYNAMICS.)

Aire-sur-la-Lys, ār-sür-lä-lē, a town of France, dept. Pas-de-Calais, 10 m. S.E. of St. Omer. It stands at the junction of the Lys with the Laquette, on a low marshy site, but is well built, and possesses several beautiful fountains, a handsome Gothic church, and barracks for 6,000 men. Its trade is chiefly in linens, fustians, hats, thread, starch, soap, Dutch tiles, osier work, and grain. Pop. (1902) 8,500.

Air-gas, an inflammable gas produced by charging air with the vapors of naphtha, gasoline, or some similar volatile hydrocarbon.

Air-gate, in foundry work, an opening left in the mold for the escape of air and other gases as the molten metal enters.

Air-gun, an instrument for the projection of bullets by means of condensed air, generally either in the form of an ordinary gun or of a pretty stout walking-stick, and about the same length. See ORDNANCE; ZALINSKI.

Air-hole (or **blow-hole**), a fault in a casting, due to the presence of a bubble of air or other gas.

Air-lock, an air-tight chamber used in tunneling, when the tunnel has to be kept filled with compressed air to prevent the entrance of water. The air-lock communicates with the tunnel by one door, and with the outside air by another. It serves the double purpose of permitting the workmen to enter and leave the tunnel without undue loss of air, and of partially mitigating the physiological effects of a too sudden transition from the high pressure in the tunnel to the lower pressure outside.

Air-plant, a popular name for plants that live upon the trunks of trees and obtain their nourishment from air and rain but not from the plants upon which they grow. See EPIPHYTE.

Air-pump, a machine invented by Otto von Guericke about 1652, by means of which air or other gas may be removed from an enclosed space; or a machine for compressing air within an enclosed space: the latter type is usually known, however, as an air-compressor (q.v.). An ordinary suction-pump for water is a rough kind of air-pump; indeed, before water reaches the top of the pipe the air has been pumped out by the same machinery which pumps the water. An ordinary suction-pump consists essentially of a cylinder or barrel having a valve opening from the pipe through which water is to rise, and a valve opening into the outlet pipe, and a piston fitted to work in the cylinder (the outlet valve may be in the piston). (See PUMP.) The arrangement of parts in an air-pump is quite similar. The barrel of an air-pump fills with the air which expands from the receiver (that is the vessel from which the air is being pumped), and consequently the quantity of air expelled at each stroke is less as the exhaustion proceeds. Suppose that the receiver or vessel to be exhausted is exactly as large as the barrel; by the first stroke there is just half the air removed, by the second there is one fourth, by the third there is an eighth, and so on. Suppose the barrel is one third of the receiver as to volume. On raising the

piston the air which filled the receiver now fills both barrel and receiver, so that one fourth is removed at the first stroke, one fourth of the remaining three fourths is removed at the second stroke — that is, three sixteenths, and one fourth of nine sixteenths at the third stroke; the quantity removed at each stroke forming a series of $\frac{1}{4}$, $\frac{3}{16}$, $\frac{9}{64}$, $\frac{27}{256}$, etc.; that is, the total quantity removed is $\frac{1}{4}$ $(1+\frac{3}{4}+(\frac{3}{4})^2+(\frac{3}{4})^3+$ etc.). At each stroke we add a term to this series, and consequently the quantity removed by each stroke becomes smaller and smaller. There are also air-pumps for compressing air — the reverse operation from exhausting air — and a compressing pump may be considered as one of the cylinder pumps above described, but having the receiver connected with the escape valve. There is not so much nicety required in compressing pumps as with exhausting pumps. It may be observed that at the commencement of the stroke the effective pressure against the piston is, we may say, 0, and when it has got to that position where the valve opens toward the receiver the effective pressure is that of the air in the receiver. It will be seen that when the pressure in the receiver is considerable the variation of pressure during the stroke is very great. It is on this account that compression-pumps are sometimes used in which a set of cylinders have their pistons worked by a number of cranks differently set on the same shaft, which shaft also carries a fly-wheel. There is some difficulty in compressing air considerably, from the heating of the pistons and cylinders, when the operation is rapidly proceeded with. Air may be compressed by sending water at pressure into an air-tight chamber containing air.

Many interesting experiments may be made with the air-pump. If an animal is placed beneath the receiver, and the air exhausted, it dies almost immediately; a lighted candle under the exhausted receiver immediately goes out. Air is thus shown to be necessary to animal life and to combustion. A bell, suspended from a silken thread beneath the exhausted receiver, on being struck cannot be heard. If the bell be in one receiver from which the air is not exhausted, but which is within an exhausted receiver, it still cannot be heard. Air is therefore necessary to the production and to the propagation of sound. For the mercury pumps that are used in exhausting incandescent electric lamp bulbs, see VACUUM.

Airship. See AËRIAL LOCOMOTION; BALLOON; FLYING MACHINE.

Air-thermometer, a thermometer in which temperature is measured by determining the change of volume of a mass of air that is kept at constant pressure, or the change of pressure of a mass that is kept at constant volume. See THERMOMETRY.

Air-trap, in steam and hydraulic engineering, a place where air can accumulate in a line of piping; as at the highest point of a line of water pipe. Air-cocks are placed at these points to permit of the removal of the accumulated air. (Also called *air-bond.*)

Airy, Sir George Biddell, an English astronomer-royal: b. Alnwick 27 July 1801; d. 2 Jan. 1892, in Greenwich. He was graduated at Trinity College in 1823. In 1826 he was appointed Lucasian professor of mathematics at Cambridge, a chair once held by Newton, and he was the first actual director of the Cambridge Observatory, holding in connection with this post the Plumian professorship of astronomy. In 1835 he succeeded Pond as director of the Greenwich Observatory, and retained this office till 1881, when he retired on a pension. He initiated at Greenwich the plan of immediately and completely reducing observations; introduced the regular observation of magnetic phenomena, and of sun-spots by photography; invented new instruments for lunar observations; and arranged the British observations in all parts of the world of the transit of Venus in 1874. His chief works were ‹Mathematical Tracts› (1826); ‹Ipswich Lectures on Astronomy› (1849); ‹Undulatory Theory of Optics› (1866); ‹Treatise of Sound› (1869); and ‹Treatise on Magnetism› (1870).

Aisle, in architecture, one of the lateral and usually lower divisions of a building which is divided lengthwise, as by rows of columns or piers, so that the roof is supported while still the interior is one large hall broken only by the uprights. The basilicas of the Romans were built in that way, as had been the small interiors of many Grecian temples; and when the first Christian churches were built in Italy and in the East, this "basilican" form rivaled the round or polygonal plan and the plan of the Greek cross in popularity. At a later time Christian churches were nearly always built with aisles and a higher central part called usually the Nave. Most churches have an aisle on either side of the nave, and are called "three-aisled" churches, but there are a few with five, and the famous Cathedral of Antwerp in Belgium has seven aisles, being almost alone in this respect. It is a mistake to count an outer row of chapels as another aisle.

By extension the term covers such a long and narrow compartment of a building as is found in one of the great mosques of Cairo, Cordova, and Damascus. These buildings have generally flat roofs intended always to be of masonry, and that structure is carried by a great number of parallel rows of columns. The resulting "aisles" are, of course, of the same height. In the mosque of Cordova there are 17 such aisles left open, besides two outer ones which are largely enclosed for chapels: all the aisles opening by doors or windows upon a large court.

Aitkin, Robert, printer and publisher: b. Dalkeith, Scotland, 1734; d. Philadelphia, July 1802. Emigrated to America, 1769; settled in Philadelphia as a bookseller, becoming later a bookbinder and publisher as well. He published the ‹Pennsylvania Magazine› (1775–6), and printed numerous documents and state papers for the Continental Congress, among them the ‹Journals of Congress› from 5 Sept. 1774 to 1 Jan. 1776 (Phila. 1777–80). At his own expense he published in 1782 the first English Bible printed in America. This is now the rarest of all early Bibles printed in America, not more than 25 copies being known to exist. In 1777 Aitkin was imprisoned for his attachment to the cause of independence.

Aivali, AI-vä'li, or **Kidonia,** ki-dō-nī'a (the ancient *Heracleia*), a town of Asiatic Turkey, on the western promontory of the Gulf of

Adramyti, 66 miles northwest of Smyrna. In the beginning of the present century it was a place of considerable note, but in June 1821, during a contest between the Greeks and Turks, it was set on fire by the latter and reduced to ashes. It has again revived, however, and (1902) possesses a population of 35,000. The olive is extensively cultivated in the district, and much oil and soap manufactured.

Aix-la-Chapelle, āss, or āx-lä-shä-pĕl' (German, *Aachen;* Latin, *Civitas Aquensis, Aquisgranum*), capital of a district of the same name in the Prussian province of the Rhine, 38 miles W. by S. of Cologne. It is a well-built town, pleasantly situated in a fine vale watered by the Wurm, and surrounded by the Venn Hills. It was formerly surrounded by ramparts, but these have been converted into pleasant promenades. The town-house (built in 1353 on the ruins of Charlemagne's palace) contains the coronation room with portraits of the German emperors, half-sized portraits of Napoleon and the Empress Josephine, painted by David, and many relics of old German art. The nave of the cathedral, erected by Charlemagne as a palace chapel between 796 and 804, was rebuilt on the old model by Otho III. in 983, after having been almost destroyed by the Normans. It consists of an octagon, surrounded by a 16-sided gallery, and terminating in a cupola. The Gothic choir was begun in 1353 and finished in 1413; it is of prodigious height (114 feet) and lightness, and the large windows are filled with stained glass. Besides the tomb of Charlemagne, the cathedral contains many relics, the most sacred of which — such as the robes worn by the Virgin at the Nativity, the swaddling-clothes of the infant Jesus, the scarf he wore at the crucifixion, etc.— are shown only once in seven years, and attract many thousands of pilgrims from all countries. As the chief station of the Belgo-Rhenish Railway, which connects it with Antwerp, Ostend, and Cologne, Aix-la-Chapelle affords an extensive mart to the commerce of Prussia; it is also a grain market for Belgium, and the seat of commercial and other courts. It was eminent as a manufacturing city, especially of cloth and needles, as early as the 12th century; and its prosperity in this respect still continues. Its woolen cloths are highly esteemed on the continent of Europe and are also exported to America, China, etc. All trading countries, including the United States, have consulates in the city. It is estimated that over 30 per cent of the inhabitants are employed in the manufactures of the city. Although Aix-la-Chapelle is an extensive seat of manufactures and has considerable commercial relations, it derives its celebrity chiefly from its historical associations, and a considerable portion of its importance and prosperity from the influx of visitors to its baths. There are in all eight mineral springs here, six of them warm. The most famous is the Imperial Spring or *Kaiserquelle,* which has a temperature of 143° F., and the vapor of which, when confined, deposits sulphur. For the accommodation of strangers there are a number of bathing-houses. The rooms for bathing are excellently fitted up, with baths from 4 to 5 feet deep, built in massive stone and in the old Roman style. About a half mile north of the city is the Louisberg or Lousberg, rising nearly 300 feet higher than the city. It is a favorite summer evening resort of the citizens.

Aix-la-Chapelle was known to the Romans as early as the time of Cæsar, and is mentioned by Pliny under the name of Vetera. It was, after 768, the favorite residence of Charlemagne, who made it the capital of all his dominions north of the Alps and spared no expense in beautifying it. Here he died in 814, and in the cathedral his tomb is marked by a large flat slab with the inscription *Carolo Magno.* During the Middle Ages it was a free imperial city, and its citizens throughout the empire were exempt from feudal service, from attachment of their goods and persons, and from all tolls and taxes. Thirty-seven German emperors and eleven empresses have been crowned in this city, and the imperial insignia were preserved here till 1795, when they were carried to Vienna, and are now in the imperial treasury. By the peace of Lunéville (9 Feb. 1801), which separated the left bank of the Rhine from Germany, the city was transferred to France, in whose possession it remained till 1814, when it was restored to Prussia. Pop. (1900) 135,221.

Aix-la-Chapelle, Congress of, an important congress held in October and November 1818. By this congress the army of the allies, consisting of 150,000 British, Russian, Austrian, Prussian, and other troops, which, since the second peace at Paris, had remained in France to watch over its tranquillity, was withdrawn after France had paid the contribution imposed at the peace of 1815. Thus the Congress of Aix-la-Chapelle restored independence to France.

Aix-la-Chapelle, Treaties of Peace concluded at. The first, 2 May 1668, put an end to the war carried on against Spain by Louis XIV. in 1667, after the death of his father-in-law, Philip IV., in support of his claims to a great part of the Spanish Netherlands, which he urged in the name of his queen, the Infanta Maria Theresa, pleading the *jus devolutionis* prevailing among private persons in Brabant and Namur. The second peace of Aix-la-Chapelle, 18 Oct. 1748, terminated the Austrian War of Succession in which the parties were at first Louis XV. of France and the Empress Maria Theresa, and, in the sequel, Spain on the one side, and Great Britain, Maria Theresa, and Charles Emmanuel, king of Sardinia, on the other.

Ajaccio, ä-yä'chō, or **Ajazzo,** ä-yät'zō, France, capital of the department and island of Corsica, on its southwest coast, on a tongue of land projecting into the Gulf of Ajaccio. It is sheltered by mountains from the north and east winds; and the town and bay are defended by a citadel. The entrance into the harbor is rendered unsafe by projecting rocks. Ajaccio is the birthplace of Napoleon; the house in which he was born is still in a state of good preservation, and has become the property of the nation. It is the handsomest city of Corsica and the seat of a bishop. It contains a cathedral, a communal college, a public library, a botanical garden, etc. In the commercial world it is famous for its coral and sardine fisheries, and it has also a trade in wine, grain, olive-oil, and fruits. Pop. (1902) 20,200.

Ajalon, said to be the modern Yâlo, a village 14 miles west-northwest of Jerusalem, was the town rendered memorable by Joshua's victory over the five Canaanitish kings, and still more so by the extraordinary circumstance of the miraculously lengthened day.

A'jax (Greek, *Aias*), the name of two of the Grecian chiefs who fought against Troy, distinguished as Ajax Oileus and Ajax Telamonius. The former, the son of Oileus and Etiopas, a Locrian, was called the Less. When the Greeks had entered Troy, Cassandra fled to the temple of Pallas, whence she was forced and dragged along, bound as a captive. Some accounts add that he violated the prophetess in the temple of the goddess. Ulysses accused him of this crime, when he exculpated himself with an oath. But the anger of the goddess at last overtook him, and he perished in the waves of the sea. The other Ajax was the son of Telamon, from Salamis, and a grandson of Æacus. He understood not how to speak, but how to act. After the death of Achilles, when his arms, which Ajax claimed on account of his courage and relationship, were awarded to Ulysses, he was filled with rage, and, driven to frenzy, threw himself on his sword, after having slaughtered the sheep of the Greek army, which he fancied were his enemies.

Akron, Ohio, city and county-seat of Summit County, is situated in a range of hills overlooking the Little Cuyahoga River. The Ohio Canal here mounts to the watershed between Lake Erie and the Ohio River by a series of 21 locks. It is 31 miles southeast of Cleveland and 98 miles northeast of Columbus. Railroads centring here are the Baltimore & O., Pennsylvania, Erie, Cleveland, A. & C., Pittsburg & W., Northern O., and Valley. The town was settled about 1818, but its growth dates from the location of the Ohio Canal in 1825, the surplus water used in lockage, furnished by a system of reservoirs on the Summit level, making the power for large flouring mills then located here. It was incorporated as a village in 1836, and as a city in 1871. Its location is advantageous for a diversified industry, being in the northern edge of the grain belt, and on the southern border of the dairy section of the State, and beds of fire-clay and coal fields being close by. It is the principal seat of rubber manufactories for the Middle West, the yearly output of these industries alone being $10,500,000, of which the B. F. Goodrich company furnishes about $6,000,000. The number of rubber workers employed is about 5,000, and the amount paid to them in wages is over $2,300,000 in the year. The printing works of the Werner Company, employing 1,200 persons, are located here. The city is also the seat of a large number of other manufactories, including the American Cereal Company, the Aultman, Miller & Company, makers of Buckeye mowers and reapers, the American Twine and Cordage Company, the American Clay Company, the Akron plant of the Wellman, Seavers-Morgan Company, where is made hoisting and mining machinery, The McNeil Boiler Company, and lesser manufactories of various kinds. At Barberton, the southern suburb of Akron, are the works of the Diamond Match Company, the largest in the world, O. C. Barber, one of the pioneers in this particular industry and founder of Barberton, being a native and resident of Akron. (See BARBERTON.) In addition to its proximity to the coal fields, Akron has facilities for manufacturing in the way of fuel, in natural gas piped from West Virginia. Under the municipal code of Ohio, Akron is governed by a mayor, council, board of public service, board of public safety, board of education, and subordinate officers. The school system alone involves the annual expenditure of upwards of $160,000, and is of a high and efficient grade. Here is the seat of Buchtel College (Universalist), founded by John R. Buchtel, the cornerstone of which was laid by Horace Greeley in 1872. The other principal public buildings are Carnegie Free Library, United States Government building, Colonial Theatre, Grand Opera House, Methodist Episcopal church, High School building, etc. The annual revenue of the city is over $1,000,000. Akron was once the home of John Brown, and his former dwelling is still standing here, where the councils of his associates in the abolition cause were held. It was also the residence of Sidney Edgerton, first chief justice of Idaho Territory, and first territorial governor of Montana. Pop. (1900) 42,728, being a gain of 54.8 per cent since 1890. In 1903 the estimated population was 61,000.

C. R. GRANT,
Attorney at Law, Akron, O.

Alabama, Gulf State of United States (No. 9 in order of admission), bounded N. by Tennessee, S. by Florida and Gulf of Mexico, E. by Georgia, W. by Mississippi; extreme length 336 m., greatest breadth 200 m., about 150 at N. border; area (No. 27 in U. S.), 52,250 sq. m., 710 water; pop. 1900 (No. 18 in U. S.), 1,828,697, or 35.5 to sq. m. (No. 26 in density). Whites, 1,001,152; colored, 827,545.

Topography.— The great Tennessee Valley, which sweeps into and out of the State across the extreme N., is bordered in its western part by a region of fertile terraces; in its eastern it separates the picturesque Cumberland Plateau on the N., a continuation of Middle Tennessee, from the declining flat-topped parallel ranges of the Blue Ridge on the S., which enter the State from N. Georgia some 1,600 feet high, and of which the Raccoon Mountains sink to low hills called the Sand Mountains extending to the centre of the State, while the Lookout Mountains end sharply about 60 miles within it. To the southwest they are succeeded by a low plateau where the great coal and iron deposits lie, to the southeast by the same "Piedmont" region of rolling upland as in all the southern States; and both decline to the great belt of level coastland which extends all around those States and comprises three fifths of Alabama's territory. The sea line is short, three fourths of its natural extent being taken up by Florida; and its only valuable part is Mobile Bay, an inlet 36 miles long by 8 to 18 broad, which receives the great river systems of the State. Other bays are the Perdido, which with the Perdido River divides Alabama from Florida, 20 miles long by 6 to 10 wide, once a nesting-place for pirates and filibusters; the Grand; and the Bon Secours.

River Systems (see also *Commerce and Navigation*, below).— The Mobile system drains the greater part of the State. The Mobile River, 45 m. long, as such, and emptying into the Mobile Bay, is formed from the Alabama E. and the Tombigbee W., very crooked alluvial streams. The Alabama is a powerful stream 800 m. long from its farthest sources, but only so named for the 320 m. from the junction of the Coosa N. and Tallapoosa E., just above Montgomery, the State capital; the Coosa, 350

CHATTANOOGA

m. long as such, is formed by the junction at Rome, Ga., of the Etowah and Oostenaula, and receives N. the Cahaba or Cahawba, rising in the mountains N.E. of Birmingham. The Tombigbee is about 500 m. long; it rises in Mississippi, and just above Demopolis, Ala., receives a large tributary, the Black Warrior, some 300 m. long, wholly in Alabama, rising near the great south bend of the Tennessee at Guntersville. The Tennessee, the Ohio's chief affluent, has about 180 m. of its course in Alabama, with a wholly unrelated drainage system. The S.E. portion of the State is drained by the Choctawhatchie, the Escambia with the Conecuh, and the Chattahoochee which divides the southern half from Georgia, all emptying in Florida.

Climate.— Alabama ranges in climate and products from the temperate to the semitropic regions,— extending from 35° to 30° 10′ N., or within 6⅔ degrees of the Tropic, and from mountain to seacoast; and still more, from northern mountain to southern coast. Parts of its cool northeastern section are noted as sanatoriums; the Piedmont region is entirely salubrious, and near the Gulf the sea winds temper the heat; along the river bottoms it is malarious. There is little snow or sharp cold in the north, nor extreme heat in the south; the mean temperature for winter is 42.9, for summer 83.9; for the year, in the north 59.70, in the south 66.60. The frost limits at Montgomery are 10 October and 25 April. Average rainfall, 54 inches in the north, 63 inches in the south; most of the rain is in early spring, especially in February.

Geology.— All the Appalachian formations are found here, in three geological divisions: (1) Northern, above a line running southeast from the northeast corner to Tuscaloosa, showing Subcarboniferous rock masses and coal measures; (2) Middle, a triangle bounded by above line and one from Tuscaloosa to Columbus, Ga., having metamorphic and calcareous rocks, Silurian sediments, and coal measures; (3) Southern, all below this, having drift beds over Cretaceous and Tertiary rocks. The angle between the Alabama and Tombigbee is rich in fossils.

Soils, Agriculture, and Forests.— Four territorial belts divide the State latitudinally. Each belt is distinguished by a variety of soils, but all soils are productive of forest trees and other wild growths. Each belt is watered in its own degree. Certain staple crops, cotton, corn, the cereals, the legumes, also garden vegetables, orchard fruits and berries, flourish in degree in all the belts. The first is chiefly the Tennessee Valley, with a red chalky soil excellent for grain, and a sheltered situation making fruit culture profitable, even delicate fruit like peaches. The mountainous districts around have much waste land, compensated by water-power, mineral springs, and healing climate; the low foothills, however, are unsurpassed grazing grounds, and the long valleys between the spurs are highly fertile. The mineral lands have generally a sandy soil, often with clay subsoil. The Piedmont region is a rolling prairie of great fertility, the metamorphic rocks having crumbled into varicolored loams with clay subsoil; around it is a forested girdle of similar loam with gravel or sedimentary rock beneath; the cotton belt is part of the famous Southern « Black Belt,» and is a slender strip of black loam sometimes many feet deep, of enormous productiveness, extending across the centre of the State. The southern coast land is sandy, but yields fair returns to labor; much of it is occupied by vast stretches of yellow pine and other woods, affording not only lumber, tar, turpentine, resins, etc., but much wax and honey, and the « pine barrens » are broken by alluvial bottoms in which rice is grown.

The chief crop of the State is cotton, in which Alabama ranks fourth in the Union,— after Georgia, Mississippi, and Texas; in 1899, out of 223,220 farms, 192,388 raised cotton; and out of a total value of all crops of $70,696,268, that of cotton was $42,069,677. The number of bales in that year was 1,106,840; in 1901, 1,103,000, from 3,447,751 acres estimated to be under cultivation. Strong efforts have been made to diversify the State's agriculture more, and not without success; but the system of renting farms by merchants to small occupiers, largely negroes, who are supplied with necessaries by the merchant on a crop mortgage, makes it difficult to effect the change, as the cotton is a less experimental crop than new ones, and the merchant wishes to sell the occupier other products himself. The partial exhaustion of even the fertile cotton land, however, by continuous planting for many years, has awakened much anxiety for the agricultural future; and the planting of cow-pease, alfalfa, etc., to enrich the soil and feed greater quantities of stock, has shown a considerable advance. Next in production to cotton is Indian corn, which is raised on nearly all farms to some extent, and in 1899 amounted to 35,053,047 bushels, with a value of $17,082,271, or nearly one fourth the total of all crops; corn and cotton thus making up nearly six sevenths of the State's crop products. In 1900, a bad year for corn, that crop had fallen to some 29,300,000 bushels. Oats are the next heaviest cereal crops, having of late years crowded out wheat; in 1900 the total output was 4,300,000 bushels against 916,000 bushels of wheat. A more valuable crop is sweet potatoes, of which in 1899 the State harvested 3,467,386 bushels valued at $1,687,039; and little behind it was the production of syrup from sugar cane and sorghum, of which 4,395,235 gallons were made in 1899, bearing a market value of $1,405,278. Peanuts are raised in the southeast. Peaches and melons are important staples. In farm animals the State is not rich, the number of swine being greatest of any, 1,866,000 in 1900.

Minerals and Mining Industries.— The mineral wealth of the State is enormous, practically all of it lying in the northern and middle geological sections. The advantage of vast coal, iron, limestone, and dolomite (magnesian limestone) deposits lying close together has within the past 20 years raised the State from an almost purely agricultural section to one of the chief manufacturing districts of the Union; its centre being Birmingham. It is said that iron products can be manufactured more cheaply there than anywhere else on the globe. The coal fields — all bituminous, but comprising all the highest grades, cannel, coking, gas, etc.— occupy 8,660 square miles; they are named from their rivers, the Warrior, Cahaba, and Coosa. The value of coal mined in Alabama has more than quadrupled in 18 years, rising from less than $2,500,000 in 1886 to over $14,000,000 in 1904, ranking the State No. 5 in quantity and

No. 6 in value in the United States. Besides its direct use and sale, a large part is manufactured into coke, in which Alabama ranks No. 3. The iron deposits so far mined are 72 per cent red and 28 per cent brown hematite, the State ranking second in the latter; magnetic, specular, limonite, and other valuable varieties are also present. The mining of this is almost entirely the development of the past two decades; in 1880 the product was but 171,000 tons; in 1889 it had risen to over 1,500,000 tons, and in 1899 to nearly 2,300,000 tons, making the State third in the Union, next after Michigan and Minnesota — really second, the great Lake Superior beds constituting but one deposit. In export of pig iron it ranks first in the Union. The limestone, used as a flux, and also burned into quicklime, is quarried to the value of above $300,000 a year. Natural gas has been found. Clays are another valuable mineral asset: notably bauxite,— an alumina with some silica and iron, used for making aluminum, alum, and crucibles,— porcelain, fire, and building clays. Building-stone is largely quarried, including a fine sandstone. Among the other of the wonderful mineral riches of Alabama are soapstone and lithographic stone, emery and corundum, asbestos and graphite, slate and asphalt, phosphates and marl, manganese and ochre, gold, silver, copper, and tin. There are mineral springs of note in the north. The marble fields of Talladega County bordering the Coosa River and of Bibb County bordering the Cahaba River are unsurpassed both in abundance of the stone and in its quality. The Italian sculptor, Moretti, whose iron statue, ‹Vulcan,› 54 feet high, was selected to represent Alabama at the Louisiana Purchase Exposition (1904) published his judgment upon practical test that no white marble known to his profession is as valuable to it in the finer grades of work as that which the Talladega quarries afford. These marbles are of many colors.

It has been only of recent years that cement beds have been discovered in the black belt. There is a flourishing manufactory at Demopolis on the Tombigbee and preparations are well advanced (1904) to construct larger plants near Selma on the Alabama. The entire area, 20 miles deep, from Selma to Demopolis, 50 miles, is underlaid with cement rock capable of producing at a cost nowhere else so low, an incalculable supply of Portland cement of the highest classification. Gold mining has (1904) received fresh impetus in the northeastern counties, where the supply is present but the mining yet problematical. The State geologist has published over his signature that the value of the phosphates of the central and southern counties of Alabama to agriculture surpasses the value of the entire coal field to commerce.

Manufactures.— The manufacturing industry of the State as a whole has nearly doubled within the past ten years. By far the greatest increase has taken place in cotton goods, which have nearly quadrupled; an advance due partly to the development of iron industries, the cotton manufacture needing constant facilities for the making and repair of machinery to be profitable. In volume the iron trades far exceed every other. The steel industry is a creation of the past five years mainly; the Alabama ores, from their phosphorus and silica, are unsuited to the acid Bessemer process, but in 1896 manufacturers began to show a preference for the open-hearth steel for which they are fitted. The following table from the census of 1900 shows at a glance the condition and gain of the leading industries:

	Value, 1900	Value, 1890
Iron and steel	$17,392,483	$12,544,227
Lumber and timber products (including turpentine and rosin, value $2,033,705)	12,867,551	8,507,971
Cotton goods	8,153,136	2,190,771
Foundry and machine shop products (iron pipe first, then stoves, car wheels, engines, boilers, etc.)	5,482,441	2,195,913
Railroad cars and car-shop work	4,172,192	1,581,207
Coke	3,726,433	2,474,377
Flouring and grist-mill products	3,310,757	3,060,452
Oil, cottonseed, and cake	2,985,890	1,203,989
Fertilizers (cottonseed meal mixed with Florida phosphates)	2,068,162	765,000
Cotton, ginning	1,218,283	213,529
Leather, tanned, curried, and finished	1,005,358	77,066

The total number of hands employed in these manufactories in 1900 was 37,347, against 20,657 in 1890. It is significant of the trend for consolidation that the number of ironworks was only 25 in 1900 against 35 in 1890; that the coking-works had diminished by 4, and the leather-dressing works by 3. As an instance of the economizing of labor, the flour and grist were turned out by 540 hands against 1,043 in 1890, though there was a considerable increase in value. There were 5,062 establishments altogether in the State, employing $70,370,081 capital and 55,432 hands, and paying $17,299,000 for wages and $46,151,026 for materials; output, $82,793,804. The liberality of the State and of municipalities in exempting cotton mills from taxation for 10 years has exerted a powerful influence upon the growth of that institution. Iron manufactories planted in the suburbs of Birmingham, 20 years ago, with the view of escape from municipal taxes by reason of distance from the corporate lines, are permitted to enjoy their original exemption notwithstanding the city now encloses them by a dense population. The policy of the State Penitentiary in mining coal on its own account with the labor of many hundreds of long term negro convicts, encourages not only manufactures dependent upon steam power, but railroads that transport the products of the mills, to anticipate a steady supply of the fuel. The great saw-mills also receive from the penitentiary a quota of steady and efficient labor.

Commerce and Navigation.— The great streams of the State, never closed by ice, afford fully 1,500 miles regular steam navigation, besides smaller boats in reaches; and improvements under way will increase this. The Mobile River and its two great constituents are navigable to Montgomery on the Alabama, 320 miles from the Mobile (the Coosa has also small steamers on it), and to Columbus, Miss., on the Tombigbee, 300 miles; and the Black Warrior is to be improved and connected with Birmingham by a canal, which will enable products to be carried to Mobile at about one fifth the present cost. The Chattahoochee is navigable to Columbus, Ga., about 300 miles up. The Tennessee's navigation is unfortunately broken by the Mussel Shoals near its western end in the State. On the Gulf the one seaport, Mobile, is a

STATE CAPITOL AT MONTGOMERY.

port of great importance, the outlet of the great river systems of the State; with a heavy trade in cotton, coal, and lumber, and soon to have a vast iron trade also. The bay of Mobile, in 1859–60, with a channel less than 10 feet deep, carried an export trade of $45,000,000, mostly cotton in compressed bales. Lighters were used to receive the cotton at the city wharves, to be towed down the shallow channel to sailing vessels waiting in the lower bay. In 1859 the General Assembly passed a law requiring the county of Mobile to issue $800,000 bonds, the proceeds to deepen the channel. The outbreak of war defeated the plan, subject to the approval of Congress. Under large appropriations of Congress, a channel more than 30 feet deep and with a top width of 280 feet from the Gulf of Mexico to the mouth of Chickasaw Creek, above the city of Mobile, has been successfully opened. The influence of this improvement on the trade of the port, especially in tropical fruits, lumber, and naval stores has been gratifying. The work of deepening the harbor still continues. In 1872 under the direction of the secretary of war, a line of canal was surveyed between Guntersville on the Tennessee River and Gadsden on the Coosa in view of pending legislation to open both of those long rivers to navigation their whole length. The line of canal surveyed was approximately 40 miles and the project was announced feasible at moderate cost.

Fisheries.— These employ about 1,000 men, with an annual catch worth about $150,000.

Railroads and Street Railways.— The railroad system of the State, which in 1850 comprised 183 miles, had increased to 1,843 in 1880, 3,422 in 1890, and 4,316 in 1901, of which 650 were built since 1895, and 118 the previous year; over 4/5 of a mile to every 10 square miles, and over 2.3 to each 1,000 inhabitants. The great railroad centre of the State is Birmingham, which has six trunk lines converging there. In 1901 there were street railway lines in 11 places in the State, operating 216.95 miles of track.

Railroad building began in Alabama at the earliest period in the use of that means of transportation in America. In 1832 the Decatur & Tuscumbia Railroad was chartered, 40 miles long, to overcome the obstacle of the Mussel Shoals in the Tennessee River by connecting the two towns that lay at either end of the shoals. The road was very crude in construction,— bar iron laid on wooden stringers, the cars drawn by mules. The rich planters of the level valley through which the line ran its entire length, built the grade by their slave labor, taking for pay stock in the road. Railroad property has grown to the proportion of approximately 1-6 of the assessable values of the State now taxed. Up to the time of secession, all the stock of the various short lines was owned in the State. Under the effects of a changed banking system, substituting the National Bank of issue, founded on government bonds in lieu of the private bank of issue, regulated alone by the State, founded on farm lands and other personal assets, with gold and silver coin to an ascertained deposit, railroad stocks and bonds are almost exclusively owned in New York and other monetary centres. The State is represented in the practical management of the railroads that penetrate its territory, in so far as domestic traffic is concerned by its own laws enforced by a railroad commission of citizens. The commission is elective at the polls and consists of a president and two associate commissioners, with an office always open at the capitol.

It had been the purpose of the State in ante-bellum legislation, enacted in the last decade of slavery, to connect deep water at Mobile with the landlocked mineral wealth of the central counties by rail. There was a definite policy to add to the export cotton trade then enjoyed by Mobile, an export trade in iron and coal. To this end several lines of railroad were chartered and supplementary assistance rendered in the initial movements to build them to completion by loans in cash taken from the "two per cent" and "three per cent" funds, funds donated to the State by the Federal government from public land sales within her boundaries. The main resources of the projected railroads nevertheless lay in the wealth of slave-owning cotton planters. The results of the war dissipated this reliance and the ownership of the lines as far as completed became promptly absorbed in the North. This change in ownership and control had two inevitable sequences, the operation of the roads in the interest of northern commercial centres as against Mobile, and the rapid extension of the mileage.

State Finances.— The assessed valuation of the State in 1901 was $284,622,937; in 1897, $251,390,135. The State tax was 5½ mills, besides a special soldier and school tax of 1 mill each. The bonded debt in 1901 was $9,357,600; and the interest charge, $448,680. The assessed valuation of the State in 1903 was $307,643,704. The present State Constitution limits the power of the Legislature to levy in any one year a greater rate than 6½ mills on the dollar State taxes. No county may levy a tax exceeding one half of one per centum by State assessment, except to pay old debts. All incorporated cities are subject to the same limitation of the power of taxation that applies to counties. The State can contract no new debt except that the governor may borrow $300,000. The governor has authority under the State Constitution to extend the present bonded debt of the State. The State bonds of all classes are now above par.

Banks.— In 1901 there were 42 national banks, with $4,075,000 capital, $1,883,750 surplus, $17,648,000 deposits, $1,968,000 outstanding circulation; 20 State banks and trust companies, with $992,000 capital and $2,328,400 deposits; 6 savings banks, with unreported deposits; and 34 private banks. The national banks in 1904 had increased to 53 with $22,000,000 deposits; the deposits in private banks then had risen to $17,000,000. The State now has an officer, the bank examiner, on a salary of $2,000 a year, charged with stated and frequent examinations of private banks. Some of the later constructed bank buildings are equal in magnificence of appointments to the best in the United States. The bankers are thoroughly organized.

Education.— The public school system of Alabama was founded on a grant of public lands by the Federal government. The principle underlying the grant is incorporated in the ordinance of 1787, enacted originally by the Congress of the Confederation for the government of the Northwest Territory. It consisted in the donation of the 16th section (640 acres) in each township of government survey to be sold or leased under the State as trustee and the proceeds accruing to be held by the State for the

exclusive benefit of public schools in the township involved. Besides the 16th section for public school support, the same act of Congress donated to the State for the benefit of a university within its bounds a large body of public lands. The lands now known as the "University Lands" are rich in coal seams and are now, although only partially developed, yielding a large supplement to its income from other sources. The 16th section fund yields a partial support to the public schools, while the State pays the university an annual interest amounting to $36,000, by constitutional proviso, on the proceeds of sales of its lands received from Congress made in the earlier history of the State.

In 1875, a State convention repealed the military constitution of 1868 under which the public schools had practically suspended. The military régime had accumulated a public debt which had utterly driven State credit away. Nevertheless the new Constitution prescribed a limit of appropriations for the schools, below which the General Assembly could not reduce the annual sum. In 1901 a State convention again assembled to revise the State Constitution. The Constitution of 1875 prescribed that the public schools should receive from the State not less than $100,000 annually. The Constitution of 1901 so enlarges the limit that the schools now receive about $1,000,000 annually. The Constitution of 1901 ordains methods of procedure under which each county may create a special school fund by taxation. In every enlargement of the public school system the result applies with exact uniformity to the two races who must have separate schools. The question of division of the school fund between the races in ratio of race contribution was raised and elaborately considered in the convention only to be defeated by a decided majority. The youth from 5 to 17 in 1900 were 329,003 whites and 281,348 colored, 610,351 in all; the actual attendance, however, was only 161,884 white and 78,549 colored, 240,433 in all, or less than half the total of white and not much over one fourth the total of colored. There were upward of 7,000 schools and 7,500 teachers, the white and colored being taught separately. Besides these there were 48 public high schools, with about 1,300 scholars; and 66 private secondary schools, with something over 1,000 pupils. There are 7 normal schools aided by the Peabody Fund, 3 of them for colored students, besides 3 private normal schools; 9 agricultural schools for given districts.

The Alabama Polytechnic Institute is the successor to the Alabama Agricultural and Mechanical College at Auburn. The institution is in a highly flourishing condition and is conducted on the military plan. A practical instruction in agriculture and mechanics is given there. Applied science in many features is taught in addition to the usual literary course. There are more than four hundred students there.

The University of Alabama rebuilt entirely from destruction during the War is now open to the coeducation of the sexes. A law department under a dean is maintained in the same grounds for education in the law. At Mobile the medical department for the education of physicians and surgeons is maintained.

There are in the State 9 men's and coeducational universities and colleges, and 9 women's; chief among them are:

Alabama Baptist Colored University (1878). Alabama Conference Female College, Methodist (1855). Athens Female College, Methodist, Athens (1842). Bailey Springs University, non-sectarian, Bailey Springs (1893). Blount College, non-sectarian, Blountsville (1890). Howard College, Baptist, East Lake (1841). Isbell College, Presbyterian (1849). Judson Female Institute, Baptist (1839). Lafayette College, non-sectarian, Lafayette (1885). Lineville College, non-sectarian, Lineville (1890). St. Bernard College, Roman Catholic, Cullman (1892). Selma University, non-sectarian, Selma. Southern University, Methodist, Greensboro (1859). Spring Hill College, non-sectarian, Mobile. Tuskegee Normal and Industrial Institute, colored, Tuskegee (1881). Talladega College, non-sectarian, Talladega. University of Alabama, non-sectarian, Tuscaloosa (1831).

Tuskegee University (q.v.) is of world-wide note for Booker T. Washington's magnificent work in elevating the colored race by industrial training. In March 1901 it had 1,050 pupils from 23 States and Territories, Porto Rico, Cuba, and Africa.

Churches.— The Baptist and the Methodist Episcopal South are the only strong denominational bodies; of the others, the chief are the Presbyterian, Episcopal, and Roman Catholic. There are about 8,000 churches of all denominations.

Charitable and Penal Institutions.— The State maintains an asylum for the insane at Tuscaloosa. It is one of the institutions of the kind that primarily owes its origin to the benevolent spirit of Miss Dorothy Dix of New England. The asylum was opened formally in 1860–1. Dr. Peter Bryce, a young physician, was then made superintendent, and held the position the remainder of his life, some 35 years. The reforms in the management of the insane introduced there by Dr. Bryce are famous the world over. There are State schools at Talladega for the blind, deaf and dumb of both races, the races kept separate. At Birmingham there is a State-supported school for the reform of white boys. At Mountain Creek the State supports a Home for Indigent Veterans of the Confederate Army. The State penitentiary is at Wetumpka, a farm of 700 acres. There is a branch farm of 4,500 acres at Spigners, 10 miles away, and on the Tallapoosa River, five miles in the opposite direction, is a third farm of 1,800 acres. The coal mines in Jefferson County operated by the State employ some 800 convicts. The saw-mills and farmers hire many. At Spigners there is a saw-mill and a cotton-mill. Ordinarily there are 2,500 convicts, 85 per cent negroes. The negro female convicts are perhaps 1 per cent of all; the white female convicts yet fewer. The net income from the penitentiary to the State in 1904 is estimated at $250,000, mostly from the coal mines.

State Government.— The State offices are held for four years, and incumbents are not eligible for re-election, and the governor not for any State office or United States Senate during or within a year after his term. The governor's salary is $3,000 per annum. The Board of Pardons consists of the attorney-general, secretary of state, and state auditor, *ex officio;* its functions are only advisory, as the governor has full power. The latter's veto power extends to

items of appropriation, but a majority vote overrules it, and a bill becomes law without his signature after a week. The legislature meets once in four years, sessions being limited to 50 days; the Senate is limited to 35 members and the House to 105. Members are paid $4 a day and traveling expenses. The statutes must be revised every 12 years; the State may not vote money for internal improvements; and revenue bills cannot be passed in the last five days of a session.

Congressional Representation.—The State has 9 representatives in Congress.

Population and Divisions.—The increase in population has been as follows: 1820, 127,901; 1830, 309,527; 1840, 590,756; 1850, 771,623; 1860, 964,201; 1870, 996,992; 1880, 1,262,505; 1890, 1,513,017; 1900, 1,828,967, an increase of 20.9 for the decade. The foreign-born population was 14,592; colored, 827,545. The colored population is largely concentrated in the "cotton-belt": in 15 selected counties the negro population was 399,397 against 122,040 white, while in 2 of them the proportion is between 6 and 7 colored to 1 white, and in others 4 and 5. The urban population is small: the largest city has under 40,000 people, and only 10 per cent of the population lives in places of 4,000 and over; these places, however, have increased from 10 in 1890 to 16 in 1900, and the negroes crowd into them.

The State has 67 counties, whose names and county-seats are as follows:

Autauga, Prattville.
Baldwin, Daphne.
Barbour, Clayton.
Bibb, Centreville.
Blount, Oneonto.
Bullock, Union Springs.
Butler, Greenville.
Calhoun, Anniston.
Chambers, Lafayette.
Cherokee, Centre.
Chilton, Clanton.
Choctaw, Butler.
Clarke, Grovehill.
Clay, Ashland.
Cleburne, Edwardsville.
Coffee, Elba.
Colbert, Tuscumbia.
Conecuh, Evergreen.
Coosa, Rockford.
Covington, Andalusia.
Crenshaw, Luverne.
Cullman, Cullman.
Dale, Ozark.
Dallas, Selma.
Dekalb, Fort Payne.
Elmore, Wetumpka.
Escambia, Brewton.
Etowah, Gadsden.
Fayette, Fayette.
Franklin, Russellville.
Geneva, Geneva.
Greene, Eutaw.
Hale, Greensboro.
Henry, Abbeville.
Houston, Dothan.
Jackson, Scottsboro.
Jefferson, Birmingham.
Lamar, Vernon.
Lauderdale, Florence.
Lawrence, Moulton.
Lee, Opelika.
Limestone, Athens.
Lowndes, Hayneville.
Macon, Tuskegee.
Madison, Huntsville.
Marengo, Linden.
Marion, Hamilton.
Marshall, Guntersville.
Mobile, Mobile.
Monroe, Monroeville.
Montgomery, Montgomery.
Morgan, Decatur.
Perry, Marion.
Pickens, Carrollton.
Pike, Troy.
Randolph, Wedowee.
Russell, Seale.
St. Clair, Asheville.
Shelby, Columbiana.
Sumter, Livingston.
Talladega, Talladega.
Tallapoosa, Dadeville.
Tuscaloosa, Tuscaloosa.
Walker, Jasper.
Washington, St. Stephens.
Wilcox, Camden.
Winston, Double Springs.

Chief Cities.—The largest place, and the commercial port of the State, is Mobile, with 38,469 population; Birmingham, the Pittsburg of the South, with 38,415 — but Birmingham has a suburban population of peculiar density, numbering of itself quite 75,000, in hourly contact with the city by electric cars. Montgomery, the capital and head of navigation on the Alabama, has 30,346. Anniston, in the Blue Ridge, another iron city and cotton mart, has 9,695; Selma, a cotton centre, on the Alabama below Montgomery, 8,713; Huntsville, in the mountains north of the Tennessee, the emporium of that region and a noted sanatorium, 8,068; Florence, the head of navigation on the lower Tennessee, 6,478; Bessemer, a new iron city, 6,358; and Tuscaloosa, formerly the capital, head of navigation on the Black Warrior, 5,094.

History.—When discovered by white men, the territory was occupied by great Indian tribes of the formidable Muskohegan stock — Choctaws, Creeks, and Chickasaws, Alibamos, and Apalachis. Hernando de Soto (q.v.) found the Indians along the upper Coosa more bountifully supplied with corn and beans and inhabiting better quarters than any of the red men he had found on his way from his landing on the Florida coast. At Mauvila, on his way westward, he found the red men well housed and fed and ready for desperate fighting to resist the invader. The first settlement was by the French under the Canadian Bienville in 1702, at Mobile, where he built Fort St. Louis; the city was founded in 1711, and was the capital of Louisiana for the next 15 years, New Orleans taking its place in 1726. Fort Toulouse was built at the confluence of the Coosa and Tallapoosa in 1714. There were the usual Indian wars and hostilities with the English traders who settled there. When France lost her American dominions in 1763 Alabama was divided at 32° 40′, the northern half being added to Illinois and the southern to West Florida. In 1779 Spain seized the latter, whose British inhabitants had not joined the Revolution, while the United States succeeded to the former. Spain by treaty yielded the territory above 31° to the United States in 1795; for a time it was claimed by Georgia. In 1798 Congress organized Mississippi Territory, with the Mississippi and Chattahoochee as western and eastern limits, the 31st parallel (the present main boundary with Florida) S., and a line from the Yazoo N.; in 1804 the northern boundary was carried to the southern boundary of Tennessee; in 1812 the territory between the Pearl River and the Perdido was annexed to it by proclamation, and in 1813 Mobile was seized and held by Gen. Jackson for the United States. Meanwhile the Lower Creek Indians, instigated by the British, took up arms against the United States and on 30 Aug. 1813 massacred a large party of settlers who had taken refuge in Fort Mims; the Upper Creeks remained loyal, but were involved in the vengeance which overtook the Indians at the hands of Jackson, who crushed them at Talladega and the Horse Shoe Bend of the Tallapoosa. (See JACKSON.) They had to give up their lands west of the Coosa and south of Wetumpka, and were gradually expropriated and finally removed west of the Mississippi. (See CREEK WAR; INDIAN RESERVATIONS.) On 3 March 1817 Alabama Territory was organized, capital St. Stephens; the first legislature met in 1818 at Huntsville. On 14 Dec. 1819 Alabama was admitted to the Union as a slave State, paired with Maine as a free State. In 1820 the capital was changed to Cahaba, in 1826 to Tuscaloosa, in 1847 to Montgomery.

Alabama was one of the earliest of the Southern States to engage in the secession movement, and Montgomery was the first capital of the Confederacy; the ordinance of secession was passed 11 Jan. 1861, 61 to 39. In the

secession convention the black belt influence was dominant, as it had been in the government of the State from the earliest period. The division of the vote on the adoption of the Ordinance of Secession was not between a dis-Union and a Union party. Two methods of dissolving the Union were under discussion, and one or the other method embraced all the delegates of the 100 holding seats, except perhaps a dozen who were unconditional Unionists. William L. Yancey, a lawyer, led the straight separate State secessionists, who were 54 in number. Robert Jemison, a capitalist, led the faction favorable to a co-operation of all the slave States for the purpose of some undefined measure of self-defense against the abolitionists represented by John Brown's invasion; William R. Smith was the representative of the unconditional Unionists. Until the military successes of the Federal government occupied the counties in the northern part of the State, the small farmers there exhibited no reluctance to volunteer in the Confederate army. Forts Morgan and Gaines, which guarded Mobile harbor, were seized; the senators and representatives resigned their seats in Congress 21 January, and on 4 February the government of the Confederacy was organized at Montgomery by delegates from the seceding States. Selma was made a leading Confederate arsenal and shipyard. The Tennessee Valley was occupied by Union forces early in 1862, the fleet in Mobile Bay destroyed, and the forts retaken by Farragut in 1864, and the whole State reoccupied April 1865. A provisional government was established by President Andrew Johnson in June 1865, by the appointment of Lewis E. Parsons, a native of New York who had long resided in Alabama, to be governor. Governor Parsons ordered an election by the full body of electors except the several classes not yet pardoned by the President, of delegates to assemble in the capitol at Montgomery September 1865. This convention made a new State Constitution, revoking the Ordinance of Secession, abolishing slavery, providing for the equality of the freedmen in rights of person and property and ratifying the Thirteenth Amendment to the Federal Constitution. The new Constitution restricted the electorate to the white males eligible. The State government set up by the new Constitution was accepted by all the departments of the Federal government and went into effect December following. The General Assembly, however, refused to ratify the Fourteenth Amendment. Thereupon the Senators and Representatives from Alabama to Congress were denied seats and by the acts of March 1867 the State government was abolished and military rule restored. Under military supervision the Constitution of 1868 was made and a civil government set up. The Constitution of 1868 remained in force until 1875, when a new one was made by the people in convention. The State was bankrupted by the carpet-bag régime, and there was great disorder in the attempt to bring the rule once more into the hands of the better classes; but these conditions have long passed away, and the reorganization of the public debt in 1876 made industrial progress possible. The State is solidly Democratic.

John Witherspoon Du Bose,
Author of 'Life and Times of Yancey.'

Alabama, a river formed near Montgomery, in the State of Alabama, by the junction of the Coosa and the Tallapoosa. It flows west and then south to its junction with the Tombigbee about 50 miles above its mouth, where it assumes the name of the Mobile, and finally falls into Mobile Bay. Steamboats ascend to Montgomery, 320 miles, but the navigation is interrupted during the season of low water. Some of the largest cotton plantations of America are situated on its banks.

Alabama, The, a ship built at Birkenhead on the Mersey by the Lairds under contract with the Confederate States at a cost of $250,000, and sent to sea as a privateer, in the spring of 1862, known as "290." The name indicated only that the vessel was, in order of launch from the builders' yards, number 290. Protest had come to the British government from the American minister at the Court of Saint James, Charles Francis Adams (q.v.), against the sailing of the ship. Meantime Capt. Raphael Semmes and 24 young naval officers from the Confederacy arrived in Liverpool with commissions in their pockets to take command. For sake of prudence Capt. Semmes ordered the "290" to sail for the island of Terceira, one of the Azores, under command of Capt. Butcher, a young officer of the British merchant marine. Semmes immediately followed as a passenger on an English ship. His armament had been already shipped to the same rendezvous. At Terceira the privateer ran up the Confederate colors, took her name as ordered by the Confederate government, and received on board as armament two pivot guns amidships and six 32-pounders, eight guns in all. The manning of the ship was 25 officers in all and about 120 men. Stores for a long cruise were taken aboard, and the vessel, equipped for both steam and sail, entered promptly upon her memorable career. On the night of 11 Jan. 1863, the United States steamer Hatteras engaged the Alabama off the coast of Texas and was sunk. The Alabama roved the seas for two years, seeking the commerce of the United States from both hemispheres. The privateer was supposed to have destroyed one half the American merchant marine, then second in tonnage only to that of Great Britain among the nations. On the forenoon of 11 June 1864 the Alabama made anchor in the port of Cherbourg, France. The intent of Capt. Semmes was to dock his ship for much-needed repairs. While Semmes was awaiting the consent of the Emperor Napoleon III. to the use of the government docks, the news of the arrival of the privateer spread over the land. Capt. Winslow, commanding the United States ship Kearsarge, lying at Flushing, was apprised of the fact by Dayton, United States minister to France, and made for Cherbourg, sailed into the harbor and out without anchoring, but took position outside. Semmes rightly construed the conduct of the Kearsarge as the equivalent of a challenge to combat. The Alabama steamed out on Sunday morning in faultless weather. The Kearsarge's machinery was additionally protected by a chain-armor covered with one-inch deal boards. However, as that part of the ship was struck but twice, the armor was of no material aid. The Kearsarge had 163 men and seven guns; the Alabama 149 men and eight guns. The metal carried by the Kearsarge guns was heavier than the

metal of the Alabama guns. The battle was fought in a circle and lasted 1 hour and 2 minutes, resulting in the sinking of the Alabama. In the first 30 minutes the Alabama lodged a rifled percussion shell near the sternpost of the Kearsarge, which from a faulty cap failed to explode. The shell is now to be seen, in the wood where it buried itself, in the ordnance museum of the navy yard at Washington. Capt. Semmes remained on the deck of his ship until it went down. He and 41 others from the sunken vessel were rescued by the Deerhound, a pleasure yacht belonging to John Lancaster, an Englishman. Many persons had come from Paris to view the battle and the hills along the coast were lined with spectators as it progressed. After the close of the war the British government paid an indemnity to American shippers of $15,500,000, representing losses inflicted by the Shenandoah (in part), the Florida (in full), and the Alabama (in full). Consult: Semmes, 'The Cruise of the Alabama' (1864); Bullock, 'Secret Service of the Confederate States' (1883); Sinclair, 'Two Years on the Alabama' (1895); also the narratives in 'Battles and Leaders of the Civil War' (1887-8), edited by Johnson and Buell. See ALABAMA CLAIMS.

JOHN WITHERSPOON DU BOSE,
Author of 'Life and Times of Yancey.'

Alabama Claims, claims against Great Britain for damages to United States shipping by Confederate cruisers — the Alabama chiefly, also the Florida, Georgia, Shenandoah, and others — built or equipped in British waters during the Civil War, and allowed to depart counter to international law (see DECLARATION OF PARIS; MARQUE AND REPRISAL) and to statutes of both countries obligating their governments to prevent expeditions from their territories against friendly powers. At the outbreak of the War the Confederacy, having no navy, commissioned privateers as of old. Great Britain issued a proclamation of neutrality, according belligerent rights to both and forbidding armament at English hands to either; but the English officials obeyed their superiors' secret wishes and their own sympathies and not their formal orders, knowing they would not be held to account for preventing $1,100,000,000 of English subscriptions to Confederate bonds from becoming worthless. Accordingly English built, stored, and manned vessels soon scoured the seas, capturing and burning United States merchantmen; and English colonial ports, especially Nassau, were safe nests for them for any length of time; while Northern vessels at best were held sternly to the letter of the law, and in some cases illegally imprisoned for many weeks in harbors they had lawfully entered to refit. The least part of the loss was the direct capture of prizes: manyfold greater were the indirect losses caused by the decline in trade from the difficulty in securing freights, the great rise in marine insurance, and greatest of all, the prolongation of the war and its increased cost while it lasted.

The Alabama case, by its flagrancy and Mr. Adams' menace, half frightened and half shamed the English government into amending its conduct, and no more privateers left England; but those afloat heaped up for it a legacy of trouble, of which the United States steadily pressed for a settlement. As early as the winter of 1862-3 W. H. Seward (q.v.) had served notice on Great Britain of a purpose to hold her to account for «negligence,» in diplomatic phrase, in enforcing her laws. From 1865 on there was no cessation in United States urgency of the claims and effort to arrive at some adjustment, including claims for «indirect damages,» above mentioned, which excited the wrath of all parties in England. At last, by the Treaty of Washington (q.v.), 8 May 1871, it was agreed that the «Alabama Claims» (which included those for depredations of other vessels) should be referred to five arbitrators; one to be named by the United States, one by England, and one each by the king of Italy, the emperor of Brazil, and the president of Switzerland; and it defined for their guidance the duties of a neutral and the phrase «due diligence.» The commission met at Geneva, 15 Dec. 1871, and named as chairman Count Federigo Sclopis, the Italian nominee. England sent Sir Alexander Cockburn; the United States, Charles Francis Adams; Brazil, Baron d'Itajuba, Brazilian minister to France; Switzerland, ex-President Jacob Staempfli. The chief English counsel was Sir Roundell Palmer; while the American side was represented by W. M. Evarts, Caleb Cushing, and M. R. Waite (later Chief Justice),— Mr. J. C. Bancroft Davis preparing its case. The decision was given 14 Sept. 1872; for its rules see GENEVA ARBITRATION. Indirect damages were unanimously barred out, on the ground that they were too indefinite to estimate under international law (q.v.); also doubtless for the reason, not openly expressed, that any nation would take its chance of going to war rather than pay such amounts, more than any conceivable war indemnity. England was held liable only for the Alabama (unanimous), Florida (4 to 1), Shenandoah in part (3 to 2), and the tenders of the Alabama and Florida (unanimous); the Retribution failed of inclusion by 3 to 2. The total amount was fixed in a lump at $15,500,000, the United States being left to settle with private claimants. That the total was sufficiently high for the direct losses is shown by the fact that eight years after the establishment of a United States court for distributing it (23 June 1874), claims for only three fifths of it had been allowed. On 5 June 1882 a second court was established to deal with the remainder.

If the award failed to content the extremists on either side,— the Americans too sore from the war losses and bereavements, and the feeling of English foul play which had made «neutrality» a national byword in war time, to give up contentedly all indirect damages; or the English who had lost their investment, and who felt that laws were made to squeeze and stretch according to national sympathies, and that every nation always did so without accountability,— the fact of such a dispute between the two foremost nations of the world being submitted to arbitration advanced enormously the cause of peace in the world (see ARBITRATION), and made a general settlement of national contests without war for the first time a rational forecast instead of a Utopia. By the curious revolution of time, the United States has had more reason to feel its hands tied by the award than England: as the greatest neutral and

trading nation in the world it has most to lose by enlarging the responsibilities of neutrals in time of war.

Alabama, University of, a coeducational (non-sectarian) institution in Tuscaloosa; organized in 1831: Professors and instructors, 50; students, 400; volumes in the library, 25,000; grounds and buildings valued at $300,000; productive funds, $300,000; income, $42,563; number of graduates, 553. The Medical School of the university is located in Mobile.

Alabama Shad. See HERRING.

Alabandite, an iron-black, submetallic mineral. It is usually granular-massive, while its rare isometric crystals exhibit very perfect cubical cleavage. The black color of a fresh surface tarnishes to a dark brown, while its streak is green. Its hardness is 3.5 to 4 and specific gravity about 4.0. Alabandite is a manganese monosulphide MnS, and contains 63.1 per cent of manganese. Some of its most important localities are in Austro-Hungary, Peru, and Mexico. It also occurs in Summit County, Col., and at Tombstone, Ariz.

Alabaster, a name applied to two substances, the one a stalagmitic or stalactitic carbonate of lime, the other a kind of gypsum or sulphate of lime. The first is often called Oriental alabaster, and is that which is mentioned in the New Testament. It occurs in caves in limestone regions, and is a translucent stone of yellowish milky color or of a deeper tinge of yellow, and sometimes marked with lighter and darker streaks like an onyx. It is found in the cave of Antiparos, the Baumann's cave in the Hartz, and is now worked in the province of Oran in Algeria. The gypseous alabaster has a fine granular texture, and is usually of a pure white color. It is softer than the other alabaster, indeed so soft that it may be scooped out with the nails; while the other kind cannot be so treated. It is found in many parts of Europe; in great abundance and of peculiarly excellent quality in Tuscany and Piedmont in Italy, also in England. It is extensively carved into statuettes and vases and often sold as «Florentine marble.» Many museums contain ancient vases and similar articles of alabaster, for which the Romans often employed this material.

Aladdin, or The Wonderful Lamp, one of the stories in 'The Arabian Nights' Entertainments.' Aladdin, the son of a poor widow, comes into possession of a magic ring and lamp, and thus becomes the master of the powerful jinns who are the slaves of the lamp and ring. Through their powers he amasses great wealth and becomes Sultan.

Alagoas, a maritime province of Brazil, deriving its name from various intercommunicating lakes for which it is noted; capital Maceio. It is bounded on the north and west by the province of Pernambuco, on the south by that of Sergipe del Rey, and on the east by the Atlantic; area, 11,640 square miles. This province has several lakes, none of them of great extent, frequented by a great variety of birds; and in the west several ridges of hills, none of them of great elevation, but generally well wooded, and inhabited by abundance of game, ounces, macaws, etc. From the extent of surface covered by lakes and by forests the climate of Alagoas is on the whole moist. The plains near the sea are generally sandy and not very fertile; but inland the soil is good, producing besides tobacco, cotton, and sugar, which are exported to Bahia and Pernambuco, rice, cocoanuts, mangoes, oranges, jack-fruit, and abundance of fine timber used for ship-building in the above-named ports and in Maceio. The forests furnish excellent building and dye woods, and much ipecacuanha. Limestone, granite, and various kinds of clay abound in the province. Pop. (1902) 515,000.

Alajuela, äl-ä-whā'la, a city of the State of Costa Rica, Central America, 23 m. W.N.W. of Cartago, and a little on the western side of the watershed between the Atlantic and the Pacific. It is connected with Cartago by rail. Pop. 16,000.

Alaman, ä-lä-män', **Lucas,** Mexican historian and statesman: b. 18 Oct. 1792; d. 2 June 1853. He was educated in Spain 1814–20, and served as minister of foreign affairs, 1823–5, 1830, 1837, 1853. He introduced European machinery; founded a museum of antiquities and natural history, and was an active official encourager of industry and agriculture, but reactionary in religion and politics. His works are, 'Dissertations on the History of the Mexican Republic from the Conquest to its Independence' (3 vols. Mexico 1844–9), an introduction to his 'History of Mexico,' 1808–30 (5 vols. Mexico, 1849–52), of scholarly impartiality in the main, filled with documentary proofs, but with a tendency to belittle the actions of those not of pure Spanish blood.

Alamanni, or Alemanni, a confederacy of several German tribes which, at the commencement of the 3d century after Christ, lived near the Roman territory, and came then and subsequently into conflict with the imperial troops. Caracalla first fought with them in 211, but did not conquer them; Severus was likewise unsuccessful. About 250 they began to cross the Rhine westward, and in 255 they overran Gaul along with the Franks. In 259 a body of them was defeated in Italy at Milan, and in the following year they were driven out of Gaul by Postumus. But the Alemanni did not desist from their incursions, notwithstanding the numerous defeats they suffered at the hands of the Roman troops. In the 4th century they crossed the Rhine and ravaged Gaul, but were severely defeated by the Emperor Julian and driven back. Subsequently they occupied a considerable territory on both sides of the Rhine; but at last Clovis broke their power in 496 and deprived them of a large portion of their possessions. Part of their territory was latterly formed into a duchy called Alemannia or Swabia, this name being derived from Suevi or Swabians, the name which they gave themselves. It is from the Alemanni that the French have derived their names for Germans and Germany in general, namely, *Allemands* and *Allemagne,* though strictly speaking only the modern Swabians and northern Swiss are the proper descendants of that ancient race.

Alamanni, Luigi, Italian poet: b. in Florence 1495; d. 1556. His father was zealously devoted to the party of the Medici, and he him-

self stood in high favor with the Cardinal Giulio, who governed in the name of Pope Leo X.; but conceiving himself to have been injured he joined a conspiracy formed against the life of the cardinal. The plan was discovered; Alamanni fled to Venice; and when the cardinal ascended the papal chair, under the name of Clement VII., he took refuge in France. But the misfortunes which befell this Pope giving Florence an opportunity to become free, Alamanni returned thither in 1527. His country sent him on an embassy to Genoa. Here he became the friend of Andrea Doria, with whose fleet he went to Spain. Charles V. soon after sailed in the same fleet from Spain to Italy to arrange the affairs of Florence and subject it to the Medici.

After this new revolution, Alamanni, now proscribed by the Duke Alessandro, went to France (1530), where the favors of Francis I. retained him. Here he composed the greater part of his works. The king esteemed him so highly that after the peace of Crespy in 1544 he sent him as ambassador to the Emperor Charles V. Alamanni discharged his office with great skill. He was held in like estimation by Henry II., who also employed him in several negotiations. He followed the court and was with it at Amboise, when he was attacked with dysentery, which terminated his life in 1556. His principal works are ‹Opere Toscane,› ‹La Coltivazione,› ‹Girone il Cortese,› etc. The English poet Wyatt imitated some of his satirical work. The writings of Alamanni are recommended by ease, perspicuity, and purity of style, but often want strength and poetic elevation.

Alameda, ä-lä-mā'da, co-extensive city and township in Alameda co., Cal., on San Francisco Bay and the Southern Pac. R.R.; 11 miles E.S.E. of San Francisco. It is the seat of the College of Notre Dame (Roman Catholic); a popular summer resort, and the place of residence of many San Francisco business men. It has numerous banks, electric light and street railway plants, the largest borax works in the world, extensive potteries, oil refineries, and ship-building yards. The government of the city is vested in a board of four trustees, the president of which is executive head. It has grown from a population of 100 in 1854 to about 18,000 in 1903.

Alaminos, ä-lä-mē'nōs, **Antonio de,** Spanish pilot: b. in Palos, Spain, about the end of the 15th century. He is said to have been with Columbus in 1599, and was the principal pilot for the expeditions of Cordova, Ponce de Leon, and others, in the early part of the 16th century. The earliest map of North America is supposed to have been prepared by Alaminos.

Alamo, ä'lä-mō, **The,** San Antonio, Tex.: a Franciscan mission house built about 1722 and called San Antonio de Valerio; after 1793 used on occasion as a fort and renamed Fort Alamo. It consisted of an oblong plaza some 2½ acres in area, enclosed by walls 8 feet high and 33 inches thick, a church, a hospital building, a convent, and a walled convent yard about 100 feet square. It has enduring celebrity as the scene of the battle and massacre of 6 March 1836, in the war for Texan independence. The fort was held by about 140 men under Wm. B. Travis, and on 23 February was invested by a considerable Mexican army (probably about 4,000) under Santa Anna, who at once began a bombardment scarcely intermitted for the next ten days. The little garrison, compelled to man the defenses day and night, and too few to relieve each other, sent desperate appeals to their outside comrades for help; but to break through the dense Mexican forces was so difficult that the only reinforcement received was 32 men on the 1st of March. At last a breach was made in the walls, and shortly after daylight on the 6th a general assault was ordered. Twice the storming party were repulsed with heavy loss of lives; the third time they gained the parapet and entered the inclosure. No surrender was offered, and the result showed that the Texans knew their foe too well to expect quarter; worn with fatigue and privation, they fought to a finish, till only five were left. These were taken prisoners, and the savage Santa Anna had them slaughtered on the spot. Three women, two white children, and a negro boy were the sole survivors of about 180 inmates. Santa Anna stated the Mexican loss at 70 killed and 300 wounded, but it is believed to have been much greater. The news of the heroic fight, «the Thermopylæ of America,» nerved the Texans in all their future efforts, and their slogan was «Remember the Alamo!» Santa Anna himself was defeated and captured at San Jacinto a few weeks later. (Corners, ‹San Antonio de Bexar,› 1890; Williams, ‹Sam Houston and the War of Independence,› 1893; J. L. Ford, ‹Origin and Fall of the Alamo,› 1896.)

Aland Islands, a group of about 80 islands and islets between the Gulf of Bothnia and the Baltic Sea, and near the mouth of the Gulf of Finland; area, 468 square miles. The principal islands are Aland, which is the largest, and gives name to the group, Lemland, Lumparland, Ekeroe, Fogloe, Kumlinge, Braendoe, Vordoe, and Hannoe. Aland, distant about 30 miles from the Swedish coast, is 25 miles long and about 22 broad. In this island is a harbor capable of containing the whole Russian fleet. The chief towns are Aland and Castelholm. The islands are now included in the province of Finland. Pop. about 19,000.

Alani, or **Alans,** one of the warlike tribes which migrated from Asia westward at the time of the decline of the Roman empire. They are first met with in the region east of Mount Caucasus, where Pompey fought with them. From this centre they spread over the south of modern Russia to the confines of the Roman empire. They were engaged in war with Rome in the time of Hadrian, but were defeated by Arrian, the general of that emperor. Marcus Aurelius had much difficulty in keeping them out of the empire, and Tacitus concluded a treaty with them (275 A.D.). About a century later those on the banks of the lower Danube were conquered by the Huns, after which most of them joined the ravaging expeditions of that people. They accompanied Rhadagais on his march into Italy, and after his defeat they settled first on the Rhine, afterward (about 411) in modern Portugal. Being there completely defeated by the Visigoths, they joined the Vandals, among whom they have become lost to history.

Alanus ab Insulis, a-lā'nus ab in'sū-lis, or **Alain de Lille**, ä-lan' dė lēl, a noted French scholastic philosopher: b. 1114; d. 1203. Of his voluminous theological writings the best known is the treatise on "The Articles of the Faith." His poem, "Anti-Claudinus, or On the Duties of a Good and Perfect Man," is one of the most celebrated poetic compositions of the Middle Ages.

Alarcon, äl-är-kōn', **Ferdinando de**, called El Señor Alarcon, a Spanish general: b. 1466; d. 1540. To his care Francis I. of France was entrusted after his capture at the battle of Pavia. He also took charge of Clement VII. when that pope was taken prisoner by the troops of the Constable Bourbon in 1527.

Alarcon, Hernando, a Spanish navigator: flourished in the 16th century; leader of an expedition to Mexico which set sail in 1540. He proved that California was a peninsula and not an island, as had been supposed previously. He penetrated in boats a considerable distance up the Colorado River. On his return to New Spain he made a valuable map of the California peninsula.

Alarcon, Pedro Antonio de, a distinguished Spanish novelist, poet, and politician: b. in Guadix, 10 March 1833; d. 19 July 1891. His critical contributions to papers, political and literary, his description of the Moroccan campaign, but especially his novels and short stories, are among the best of their kind, and present a picture of modern Spanish society as true to life as it is variegated. His clever essay, 'The Poet's Christmas,' went through over 100 editions. An imposing number of his stories appeared under the collective titles 'Love and Friendship,' 'National Tales,' 'Improbable Stories.' Among them 'The Three-Cornered Hat' and 'The Scandal' deserve special mention.

Alarcon y Mendoza, ä-lär-kōn ē män-dō'thä, **Don Juan Ruiz de**, a noted Spanish dramatist: b. in Tasco, Mexico, about 1588 or 1590; d. 4 Aug. 1639. Little is known about his early life, but he went to Spain in 1600 and became royal attorney in Seville. From 1608 to 1611 he was in Mexico; then he took up his residence in Madrid, where he was appointed reporter of the royal council of the Indies, about 1628. The last great dramatist of the old Spanish school, he may be considered also the creator of the so-called character comedy. Elevated sentiment, harmony of verse, and correctness of language distinguish his works, the principal of which are 'The Weaver of Segovia'; 'Suspicious Truth,' the model for Corneille's 'Liar'; 'Walls Have Ears'; 'The Proof of Promises'; 'The Anti-Christ.' A complete edition of his works was published by Hartzenbusch in Madrid 1866.

Al'aric I., king of the Visigoths: b. about the middle of the 4th century; d. 410, and is first mentioned in history in 394 A.D., when Theodosius the Great gave him the command of his Gothic auxiliaries. The dissensions between Arcadius and Honorius, the sons of Theodosius, inspired Alaric with the intention of attacking the Roman empire. In 396 he ravaged Greece, from which he was driven by the Roman general Stilicho, but made a masterly retreat to Illyria, of which Arcadius, frightened at his successes, appointed him governor. In 400 he invaded Italy, but was defeated by Stilicho at Pollentia (403), and induced to transfer his services from Arcadius to Honorius on condition of receiving 4,000 pounds of gold. Honorius having failed to fulfil this condition, Alaric made a second invasion of Italy, during which he besieged Rome thrice. The first time (408) the city was saved by paying a heavy ransom; the second (409) it capitulated, and Honorius was deposed, but shortly afterward restored. His sanction of a treacherous attack on the forces of Alaric brought about the third siege, and the city was taken, 24 Aug. 410, and sacked for six days, Alaric, however, doing everything in his power to restrain the violence of his followers. He quitted Rome with the intention of reducing Sicily and Africa, but died at Cosenza.

Alaric II., king of the Visigoths from 484 to 507 A.D. At the beginning of his reign the dominions of the Visigoths were at their greatest extent, embracing three fourths of the modern Spain and all western Gaul to the south of the Loire. His unwarlike character induced Clovis, king of the Franks, to invade the kingdom of the Visigoths. In a battle near Poictiers (507) Alaric was slain and his army completely defeated. The 'Breviarium Alaricianum,' a code of laws derived exclusively from Roman sources, was compiled by a body of Roman jurists at the command of this King Alaric.

Ala-Shehr, ä-lä-shār', ancient Philadelphia, a town in Turkey in Asia, 76 miles east of Smyrna, famous as the seat of one of the first Christian churches, and still having a vast number of interesting remains of antiquity, consisting of fragments of beautiful columns, sarcophagi, fountains, etc. It is a place of some importance, carrying on a thriving trade, chiefly with Smyrna, to which runs a railway. Pop. 19,000.

Alaska, Inuit al-ak-shak or al-ā-ek-sa, "great land," formerly Russian America; a Territory of the United States, the N.W. extremity of the continent; bounded N. by the Arctic Ocean, S. by the Pacific Ocean, E. by Canada (Yukon District and British Columbia), W. by the Arctic Ocean, Siberia, and the Bering Sea. Lat. 54° 40' to 71° 30' N.; lon. mainland 141° to 167° 59' 12" W., to the farthest island (Attoo) about 187°. Length, mainland about 1,150 m., Aliaskan Peninsula and islands 1,500 m. (as far west of San Francisco as Maine lies to the east); breadth N. to S., about 850 m.; coast line, about 8,000 m.; area, 590,884 sq. m. Pop. (1900) 63,592 (for items see *Population*, below); (1902) about 90,000. Capital, Sitka (formerly New Archangel), in the extreme southeast.

Size of Alaska.— For many reasons, but chiefly because of its distance from the United States and the present difficulties of travel in its interior, the size of the territory has been but little understood and probably much underestimated. The mere statement that the area of Alaska is nearly 600,000 square miles will give but a vague idea of its vast extent. If it were possible to take the whole territory of Alaska and its adjoining islands and place them upon the portion of North America occupied by the

United States, it would be a simple thing to show exactly the proportionate size of this great possession. This, in effect, has been done, as the accompanying illustration demonstrates. The chart was prepared by Mr. Alfred H. Brooks of the United States Geological Survey. It shows that the Territory of Alaska is sufficient in geographic extent to reach from the Atlantic to the Pacific and from Canada to Mexico. Placed in this position on the United States, Alaska would cover 23 States and Territories and the western third of Lake Superior.

Topography.— Alaska consists of: (1) A squarish block with the oceans on all sides but the east. (2) A strip of mountain coast 50 to 75 m. wide, for some 500 m. further southeast, the last 300 m. fenced from the ocean by a wonderful maze of 1,100 forested mountainous islands called the Alexander Archipelago, 13,000 sq. m. in area, and separated by glacier-cut channels variously styled sounds, straits, canals, entrances, inlets, etc. They are divided from the mainland N. by Cross Sound,— the ocean opening of the great Klondike route, where the fiord Lynn Canal, an inlet about 100 m. long, leads to passes over the mountains,— the beginning of a striking physical change, where the St. Elias Range and the greatest glaciers begin and the greatest forests end; and from Queen Charlotte Islands (Canadian) by Dixon Entrance. The chief of these islands are (from the north) Chicagof, Admiralty, Baranof (containing Sitka), Kulu, Kupreano, Zarembo, Prince of Wales (the largest), and Revillagigedo. (3) To the southwest the Aliaska Peninsula, about 450 m. long, and a chain of some 150 islands, 31,000 sq. m. in area (the Aleutian Islands or Archipelago) over 1,000 m. further, nearly to Kamchatka. Bering's and Copper islands, near the Siberian coast, belong to Russia. They are divided into groups, known as the Fox (the first of which, Unimak, is the largest of the archipelago), the islands of Four Mountains, the Andreanof, the Rat, and the Near islands. The southern part of the main body is a vast concave called the Gulf of Alaska, its two arms the southeast coast and Aliaska; the latter divided from the north mainland by Bristol Bay, and nearly made an island by the great Iliamna Lake, the Nikhkak "loch" N.E., and their river outlet S.E. To the east, but physically belonging to the first division, is the important Kenai Peninsula, divided from it and the mainland by Cook's Inlet, nearly cut off by Turnagain Arm, and separated on the east by Prince William Sound. Half the western side is taken up by a deep concavity, its cusps being Cape Romanoff on the south, and Point Hope and Cape Lisburne to the north. From its centre projects the huge tooth-shaped Seward Peninsula, divided from Siberia by Bering Strait; the western extremity being called Cape Prince of Wales,— only 48 m. from East Cape (the extremity of the Kamchatka Peninsula), with the Diomed Islands between,— and the southern point being termed Cape Nome. The bays south and north of it are styled Norton Sound, off Bering Sea, and Kotzebue Sound, off the Arctic Ocean. The northernmost point of Alaska is Point Barrow, where Franklin's second Arctic expedition ended its course. St. Lawrence Island, about 150 m. long, lies between Cape Romanoff and the Siberian peninsula, but nearer the latter; and the Pribyloff Islands of seal fame are out in Bering Sea, about 250 m. northwest of the point of Aliaska.

Alaska compared with the rest of the United States.

Physically the Territory may be divided into four sections, climatically and productively distinct: the Coast-Mountain, the Insular, the Basin, and the Yukon-Arctic Districts.

1. The Coast-Mountain District.— Apart from the islands this consists entirely of two great mountain ranges, geologically distinct, with a gIaciered plateau between them. One (the St. Elias Range) starts at Cross Sound where the coast from northwest turns west, and hugs it closely to Prince William Sound. The other (the Coast Range) comes from the United States and Canada, and runs parallel to the coast till it turns, with a narrow table along the sea; continues northwest behind the St. Elias to about 63° N. lat., forming the western watershed of the upper Yukon; then turns southwest in a stupendous range called the Alaskan Mountains of the Kenai and Aliaskan peninsulas, forming the watershed of the Tananâ and Kuskokwim valleys. The coast range proper is a series of irregular spurs with peaks 6,000 to 8,000 ft. high, the permanent snow line being at an elevation of about 2,000 ft. The Alaskan Range is the highest elevation in North America: flanked on the east by the grand isolated volcano Mt. Wrangell (eruptive early in the 19th century), then from lower summits rising steadily to the west till it culminates in enormous nameless peaks, crowned by a named one, Mt. McKinley, 20,460 ft., the summit of the continent. Of the other peaks in this range, measurements have been taken of Hayes, 14,500 ft.; Sanford, 14,000; Tillman and Drum, 13,300 each; Iliamna and Redoubt, volcanoes, about 12,000 each; and Lituya, 11,832 ft. The St. Elias Range is far loftier, narrower, and more regular than the Coast Range, and next to the Alaskan the highest land on the continent. The part beyond Yakutat Bay is known as the Chugach. Mt. Crillon, near Cross Sound, is 15,900 ft. high; Mt. Fairweather just north, 15,292; Mt. Vancouver, above Yakutat Bay, 15,666; Mt. Cook, above Malaspina Glacier, 13,758; Mt. St. Elias (q.v.), 18,024. The highest peak of this range, Mt. Logan, back of Mt. Cook (19,500 ft.), is in Canada.

The seaward flanks of all these mountains bear in most places fields of everlasting and ever-fresh ice, from which move down to the coast through the valleys the rivers of ice called glaciers; but the St. Elias has scarce anything else, the Chugach producing the most enormous ones on earth outside the polar regions. The Swiss glaciers beside them would be nameless and disregarded rills. These ice-rivers have plowed their valleys into deep gorges, sinking for miles inland far below sea-level and creating the fiords or narrow steep-walled mountain bays with which the coast is fringed, and making islands of the lower coastal lands. Every gorge down to the head of its fiord is choked with these ice-streams, pushing swiftly down and breaking off hourly in an amazing number of gigantic icebergs; and where there is a strip of coast between the mountain-foot and the sea, they bank up and spread out over it in titanic ice walls of many miles frontage. The tremendous Malaspina Glacier, which lies along Yakutat Bay and the coast beyond, is the most notable of these: it is 1,550 ft. high, and has an area of 500 to 600 sq. m. Valdez Glacier at Prince William Sound runs 15 m. along the coast, full of death-dealing crevices. The most familiar are those along the Klondike route: Muir Glacier at the head and east end of Glacier Bay, over 200 feet high and 3 m. long, and Pacific Glacier to the west of it, off Fairweather Mountain. Other vast ones are Miles Glacier off the mouth of Copper River, and Baring Glacier just east of it.

Real rivers are naturally few in this district. The little Chilkat running into Lynn Canal is familiar from the pass above it. The largest is the Copper River, with a considerable affluent, the Chechitna, both unnavigable from rapids. Nearly as large and more valuable is the Sushitna flowing into Cook's Inlet, navigable for 110 m.; its affluent, the Yentna, is navigable for 100 more, and leads to a pass into the Kuskokwim Valley. The Knik empties into a fiord of Cook's inlet, and has an arm, the Matanuska.

2. The Insular District comprises the Aliaskan Peninsula and the Aleutian Islands, the southwestern continuation of the Alaskan chain nearly to Siberia; the lower levels sinking under the ocean, and for over 1,000 miles only the tops showing as islands, though these sometimes rise thousands of feet about the waves. Of the 150 composing the chain 61 are volcanoes, of which 10 are sporadically active; the monarch of all is the grand Shishaldin, 8,000 ft. above the sea. Akuten, Mashunin, and others, are also on fire. Bogoslov was thrown up by volcanic action in 1796. They have grass and shrubs, but no trees. The great wooded Kadiak Island, just east and near the mainland, is a prolongation of Kenai Peninsula and belongs to the first group.

3. The Basin District.— This is the great space enclosed by the Alaskan Mountains southeast and the Lower Yukon watershed (a rather low one), and drained into Bering Sea by the Kuskokwim, a large but shallow and bar-obstructed stream rising on Mt. McKinley. Its somewhat sheltered position gives it a climate possible for civilized existence and available for pasturage and some hardy crops in the lower valley, while the upper valley leads through rich mineral lodes.

4. The Yukon-Arctic District.— The Yukon River (q.v.), one of the chief in the world, emerging from Canada, runs for a long distance in a mountainous plateau; as do its tributaries, the Porcupine, which enters from the northeast at what was Fort Yukon north of the Arctic Circle; Birch Creek, from the southeast not far below, through a now famous mining district; and the Tananâ, rising near Mt. Wrangell, flowing along the eastern and northern flanks of the Alaskan Range, and entering the Yukon about 152° W. lon. In its lower course the Yukon cuts through a vast swampy moor. The coast to the north is mountainous to Point Barrow, including the great central western peninsula; the interior west of the Porcupine Hills continues the moor, sloping to the interminable wastes of tundra (a treeless plain full of ponds and swamps cut up by small valleys) that stretch to the Arctic Ocean. The coast north of the delta is mountainous. Kotzebue Sound receives three large rivers, the Selawik, Kowak, and Noatak; and into the Arctic Ocean on the northern side flows the Colville through vast tundra wastes.

Climate.— The climate of the entire Coast-Mountain and Insular districts is dominated by the two influences of the mountain barrier and the Japanese «Black Current» or Kuro Shiwo (q.v.), which flows along it to California. The former shields the coast from the Arctic winds;

A DOG TRAIN IN ALASKA.

Dog train used in carrying furs from distant inland points. These dogs are half wolf and are remarkably powerful. They can endure the severest cold and wilt quickly in an average summer day of a temperate climate.

the latter fills the air with warm vapors which the prevailing western winds drive against the icy mountain flank, condensing them into almost perpetual rain or fog. The annual rainfall of the southern strip is from 60 to 90 inches (a fall of 156 inches has been known); and the days of rain in the year average from 190 to 285. August and September are specially rainy months. For the same reasons the temperature is less extreme than in districts east of the Rocky Mountains; up to Sitka it is about the same as that of British Columbia. It rarely exceeds 0° or 80°, and is isothermal at 40° annual mean with the lower St. Lawrence, the Rocky Mountains deflecting the line northward. Going north and west there is greater cold, snow and wind; Cook's Inlet, however, is for some reason free from fog. Along the coast of Norton Sound, where the mountainous coast and the warm current flowing into Bering Sea still exercise a tempering influence, the weather remains milder than in the interior, with winters less long and rigorous. But inside the mountains, where their shelter, the moderating current, and the vapors, are all absent, semi-arctic conditions prevail. In the Kuskokwim Valley the average temperature from December to March is about zero, and on the Lower Yukon at Nulato (about 65° N. lat.) it is about — 16°. The Yukon freezes to a depth of from 6 to 9 feet. There is a short warm summer and a very long intense winter in all this district,— the former uncertain, the latter sure; the cold sinks to — 50° in spells. Farther north the climate is pure Arctic: at Point Barrow (where the government keeps up at times a whalers' relief house and a weather observatory) the annual mean is 25°; and the northern tundra has a permanent layer of frozen soil 6 or 8 feet thick from about 3 feet below the surface.

Flora.— The moisture and temperate climate of the southern strip has bred the same gigantic forests which cover the entire northern Pacific coast from northern California upward; their great size and commercial value ending at Cross Sound, and they change to quasi-arctic conditions, but reaching in lesser proportions to Kadiak Island. The deciduous trees are rather small, except the poplars, which are often of great size; but enormous evergreens clothe all the mountains to the snow line and cover all the islands. The many thousands of square miles of white pines, cedars, and firs will soon become of prime importance to a world wasting its trees so fast. Most valuable of all as timber is the yellow cedar (*Cupressus nutkaensis*), a straight-grained and highly durable wood, from which the Haida Indians make their remarkable dugout canoes, sometimes 75 feet long by 8 to 10 wide, and carrying 100 people. The balsam fir is used for tanning. But the local wood-of-all-work is the Sitka or Alaska spruce (*Abies sitchensis*), the most universal of Alaskan trees, reaching in stunted form to the Arctic Circle, but large enough for much utility only on the southeastern and southwestern coasts. It is too knotty for fine boards; but for rough lumber, house or mining timber, firewood and lightwood, sledges, etc., it is the great resource of natives and foreigners alike. The Aleutian Islands have only berry bushes and dwarf willows. The hills of the lower Kuskokwim have little wood; but the mountains of its earlier course have heavy spruce forests on their sides, and the valleys are thick with shrubs, grass, and tall flowering herbs. The northwestern hills are naked. The Yukon-Arctic tundra has only in permanence low bushes and dwarf scrub spruce and willows, though the brief summer brings out a profusion of herbage.

Fauna.— That of Alaska is of immense variety and commercial importance. The fur animals are of course first in popular interest. Most valued is the sea-otter (*Latax lutris*) of the southern coast, once plentiful and the means of livelihood of many Aleut trappers; but for that reason it is now nearly exterminated, only 154 being caught in 1889. The marten, the wolverene, and the coarser-furred ermine are common; sables are found in the forests; and mink, muskrat, and some though diminishing otter and beaver in the rivers. Foxes are of several kinds and among the most valuable of fur animals; the white arctic fox is found on the western coast and the northern islands; the blue fox on the Aleutians, where it is regularly bred for its fur; red and cross foxes in all parts; the black fox in the eastern mountains. Bears (q.v.) include the grizzly, black, polar, and glacier, and the gigantic Kadiak varieties. Gray wolves, the ancestors of the sledge dog, furnish a coarse fur, and lynxes and smaller animals, finer varieties. Fossil-elephant ivory is an article of commerce. The food animals include the moose of the Kuskokwim Valley; the caribou-reindeer, once numerous, but now nearly exterminated, though the government is attempting to stock the country with Lapland and Siberian reindeer; the arctic hare and porcupine, marmots, squirrels, and lemmings; with sheep and goats in the southeastern mountains. The list of birds and mammals of purely scientific interest is very great, but cannot be given here. Swarms of insects are as numerous and formidable as in the tropics; especially mosquitoes, which rise in throngs to the very shores of the Arctic Ocean, sting even bears and moose around the eyes till they are maddened into miring themselves in the swamps, force the native hunter to wrap his head in furs, and make a settled lowland class almost an impossibility.

Seals, Whales, etc.— The fur seal once swarmed all along the western coast and the Bering Sea islands, but now resorts solely to the Pribyloff and Copper islands. The former were leased many years ago to the Alaska Commercial Company, under contract to kill only 100,000 adult males a year, no females or very young males. As the herds showed signs of exhaustion, the number was reduced to 30,000; but the company is now able to secure little more than half that number, as pelagic sealing — before the herds reach the islands — is rapidly annihilating them. Forbidden by the United States to its subjects, this pelagic sealing was done by Canadians (some, perhaps, with American capital behind them), who killed many more at sea than the company does on the islands, and without restriction of kind. The United States tried for years to have Great Britain join in suppressing the slaughter; but that country would not antagonize Canada to the behoof of the United States (though to its own also, as the seals furnish the most important fur of the world). At last, in 1902, Great Britain formed a protective agreement with the

United States; on which the Canadians took shelter under the Japanese flag and went on slaughtering as before. Unless all the great Powers join hands, the practical extinction of the fur-seal is predictable in no long time, with the destruction of the livelihood of many native Alaskans. The other seals, though of no moment to civilized trade, are the very life of the natives, who shoot and spear them for food, dress, boots, tents, boats, dog harness, whips, etc., and use the skins in barter. The walrus fills a similar function to the Eskimo around and north of Bering Strait; but its hunting by civilized men for ivory is also exterminating the race. The natives also rely much on whales, which are likewise hunted by the whaling fleets, which take about 150 a year, and often linger too long and are frozen in for the winter; thus arctic conditions render the extinction of the whale unlikely.

For *Fisheries, Agriculture, Commerce and Transportation*, etc., see ALASKA, RECENT DEVELOPMENT OF. See also FUR TRADE, THE.

Geology.— Alaska is geologically one of the latest portions of the continent. The west coast and the Aleutian Islands are of very recent volcanic upthrow; and the entire peninsula islands and Bering Sea basin are still rising. The activity of the forces now at work is shown not only by the vast number of volcanoes eruptive or but recently so, but by the great number of valuable hot mineral springs of every chemical character. The southeastern strip and archipelago are believed to be later than the Triassic period; they are part of the Rocky Mountain granitic system, overlaid by sedimentary rocks. The St. Elias is thought to be the youngest range on the continent, and post-Tertiary in elevation.

Minerals.— Coal is found in many places, from the upper Yukon to the Aleutian Islands and Cape Lisburne, where it is now and then utilized by whalers or revenue vessels. Much money has been sunk in mining it: but it is a sulphurous lignite, endurable only for household use, and it has been found cheaper to import coal for making steam. The iron is also poor. Copper, galena, marbles, and petroleum are other products as yet not much exploited.

The all-important mineral product so far is gold, in which Alaska promises to take high rank. The Russians and trappers knew of gold sands and placers, but the Russian government did not wish prospecting in a district utterly beyond effective control. With its acquisition by the United States a new policy prevailed, and prospectors began an active search for precious metals. The first great discovery was made on Douglas Island, in the Alexander Archipelago at the foot of Lynn Canal: the first placer, which drew together a mining-camp; then of the quartz ledges they had crumbled from, which in the hands of a powerful corporation rank among the richest mines of the world, keeping 1,500 stamps busy, and making the island and adjoining mainland one huge mine, connected by a tunnel under the water. Exhaustless water-power close by, and the ore cars running down to the stamps by their own weight, enable very low-grade ores to be worked at a high margin of profit. Profitable mines have also been opened near by, and the town of Juneau is built up by this interest on the mainland shore opposite. Other mines are worked in various islands of the Archipelago and along the shores, some around Sitka, some on Lynn Canal. Placer mining and sand-washing have also yielded a good return at Yakutat Bay and on the islands and shores about Cook's Inlet. Greater still were the discoveries in the Yukon basin, instigated by the Klondike placer finds higher up the river on Canadian soil in 1896–7. The whole upper Yukon was eagerly prospected, and very rich deposits found, especially in the valleys of the affluents Tananâ and Birch Creek, which produced about $1,000,000 in 1900. But greatest of all was the result of washing the beach sands on Norton Sound; those at Cape Nome were found in 1898–9 to be so rich that the neighboring streams which fed them were searched, and some of the richest placers on the earth revealed. The return of the washing was fully $4,000,000 in 1900. The whole Territory produced $8,171,000, or 395,039 ounces of fine gold, against 121,766 ounces valued at $2,459,500 in 1899, or 3⅓ times increase in one year.

Population.— Rough estimates were made by Russians in 1839 and 1863, with results of 39,813 and 30,434 — the latter certainly the more nearly accurate. In 1880 the first United States census was attempted under many difficulties, and found 430 whites, 1,756 half-breeds, and 31,240 natives — 33,426 in all. In 1890 a closer computation fixed the total at 32,052 of all kinds. In 1900 it was returned at 63,592: native Indian, 29,536; Chinese, 3,116; Japanese, 279; negro, 168; white, 30,493, of whom only 3,200 were female. The Chinese were mostly in the southern salmon canneries and lumbering industries. Of the increase of 31,540 over 1890, pretty much all white, 23,435 was in the Yukon basin. Making allowance for errors in former calculations, the natives had fallen off somewhat. In the past two years more than 25,000 men are estimated to have poured into the Nome district, making perhaps 90,000 altogether, about 60,000 being white.

The native races of Alaska are from four main stocks: (1) The Eskimo (q.v.), occupying originally most of the interior and coasts. (2) The Athabascans (q.v.), who occupied the upper Yukon Valley and Eastern mountains, and the southern coast from Yakutat Bay to Cook's Inlet. (3) The Aleuts (see ALEUTIAN ISLANDS), of the Aliaskan Peninsula and the islands beyond. (4) The Thlinkeets (q.v.), from Yakutat Bay to Puget Sound, a superior race. The Alaskans as a body are of a far higher type than the Red Indians — a fact which makes the theory of the peopling of America from Siberia improbable. They have not needed to be put in reservations, as they have not the fickleness or ferocity of the Red Indians, have a far better forecast of the future and greater willingness to labor steadily, and have readily taken up civilized individual employments. There is no industry brought in by white men in which natives cannot be employed, though they are debarred from several by the refusal to admit them to citizenship. Unfortunately the rapid killing off of the land and marine animals and river fish by white companies is impairing their old livelihoods, and liquor and alien diseases are decimating them; the Aleuts are nearly exterminated.

COURTESY OF DOUBLEDAY, PAGE & CO. Photographed by Miles Bros.

1. City of Skagway. 2. City of Dawson.

Government.— Alaska, like other Territories, is governed by United States officials: there is a governor resident at Sitka, a surveyor-general, courts and judges, etc. There is no Territorial legislature, however; but municipal self-government is allowed to towns of some size. It is divided into three judicial districts, with headquarters at Juneau, Eagle City, and St. Michael; the judges may appoint commissioners in their districts to act as civil and criminal officers, recorders, judges of probate, etc. A criminal code was given it in 1899, a civil code in 1900.

Education and Religion.— In 1900 the United States appropriated $30,000 for public schools in Alaska, and maintained 25. Towns may tax themselves for school purposes. Mission schools are maintained by various Protestant bodies (who are active in Christian work here), and the Russian Greek Church, which also sustains churches. An industrial training-school at Sitka is supported by the Presbyterian Church. The majority of the natives are Christianized.

History.— The peninsula and strait were discovered in 1728 by Vitus Bering, a Danish navigator in Russian service. He explored the coast and islands in 1741, and Russian adventurers entered the country, maltreating the natives so that they once provoked a massacre which was frightfully avenged. Capt. Cook explored the coast in 1776, discovering Cook's Inlet. The same year the Russians organized a company for the Alaska trade, and in 1784 made the first permanent settlement at Three Saints, on Kadiak Island. In 1790 they made the famous Alexander Baranov manager. He established a colony on Bering Strait in 1796; in 1799, when the Russian-American Company was organized, with a 20-year monopoly, extended in 1820 and 1844, Baranov, as their manager, took possession of the island named after him, founded Sitka, and began an extensive trade with the natives which was afterward extended to China and the Atlantic ports of the United States. Under its auspices the Russian Greek Church established many missions. A scheme to lay a cable under Bering Strait, for which energetic explorations were carried on 1864–7, was superseded by the Atlantic cable. But the territory never paid its expenses to Russia, which was saddled with claims on its behoof and was anxious to be rid of it. During the Civil War she was actively friendly to the United States government, putting warships at its disposal; and as a disguised payment the government, on the advice of William H. Seward, secretary of state,— who had an enthusiastic belief in Alaska's future,— took the territory off her hands in March 1867, paying $7,200,000 for it. On 18 October the American forces took formal possession at Sitka, and the next year the United States customs, etc., laws were extended over it. The United States and Russia claimed joint ownership of Bering Sea as an inland water, to protect their seal-fisheries; Great Britain could not be expected to allow the claim for so vast an oceanic body, especially when urged by Canadian sealing interests, and the seizure of Canadian sealing vessels by the United States caused an acrid international dispute for years. At length in 1902 a protective agreement was entered into between the two nations; for its results see *Seals, etc.*, above. There was also an old contention as to United States and Canadian boundaries, not pressed because the districts in debate were reckoned worthless. But the gold discoveries on the Yukon in 1896–7 and at Cape Nome in 1898–9 (see *Minerals* and *Chief Towns*, above), with the vast influx of population, made some settlement imperative; for years no decision was arrived at beyond a *modus vivendi*, the rival claims covering too much of value, but on 3 Sept. 1903 the ALASKAN BOUNDARY COMMISSION (q.v.) met in London to determine the matter. The chief crux was over the district around Lynn Canal, Canada claiming the ports at the head which form part of the main Klondike routes,— Skagway, Dyea, and Pyramid Harbor.

Although it is of evident importance that the United States navy should in case of a crisis be able to obtain coal supplies at Sitka, no coal is kept there by mercantile companies, and the navy has frequently been embarrassed for want of such supplies in the protection of American seal and other interests. In May 1903 preliminary steps were taken for the establishment of a coal station at Dutch Harbor. This port is in the northern part of Unalaska (q.v.), one of the Aleutian Islands, and is on the direct commercial routes between the ports of Bering Sea and southern Alaska and the Pacific coast of the United States. It is also on the line of steamers passing through the Unimak Pass, most of which make it a port of call. Dutch Harbor will form the fifth station in the chain of coal depots along the Pacific Coast, which will begin at San Diego and include San Francisco, Puget Sound, and Sitka. The fact that Alaska is separated from the States by hundreds of miles of coast line in a foreign domain, constitutes a strong reason why that great territory should be provided with its own coaling stations. Territorial status was granted to Alaska 6 June 1900.

Alaska, Commercial. The United States purchased Alaska from Russia, in 1867, for $7,200,000. Prior to the purchase and for some years, chiefly after the discovery of gold in Cal-

ifornia in 1849, a considerable trade in fish, lumber, and ice, had been built up between San Francisco and Alaska. On that point, the Hon. O. P. Austin, chief of the Bureau of Statistics of the Department of Commerce and Labor, in his monograph on Alaska, published in 1903, says: "Commercial companies were formed in San Francisco and Alaska to engage in that trade, and the information thus obtained regarding Alaska and its possibilities, formed some of the causes which led to the favorable consideration of the proffer of sale of Alaska, made by the Russian ambassador at Washington to Secretary of State Seward, in 1864, and completed in 1867." Thus was the vast territory of Alaska and the Aleutian Islands acquired and added to the national domain of the United States for what is now the value of the country's internal commerce, for only one hour, reckoning that commerce at twenty-two thousand million dollars a year, the working days at three hundred yearly, and the working hours at ten for each day.

Great progress in Alaskan matters generally, and in its value to the United States has been made since the day on which "Seward's Iceberg" was acquired, but even yet only the fringe of Alaskan possibilities has been touched. With the acquirement of Hawaii, Guam and the Philippine Islands, undreamed of in Seward's day and until a very few years ago, with the farthest point of the Aleutian Islands almost touching the farthest point of the Empire of Japan, with the Philippines within as easy reach of Japan as New York is of Liverpool, and with the prolific territory of Hawaii and Little Guam as milestones on the American way across the great Pacific, who can measure the present commercial possibilities of Alaska, with its wealth of furs, fish, gold, coal, iron, and other minerals? Those possibilities cannot be measured, but a brief study of what has been done and is being done, will afford us a glimpse of what the womb of the future has in store for the Alaskan interests of the United States.

Area and Population.— According to the census of 1900 the gross area of Alaska is 590,804 square miles. In a recent report the governor of Alaska states that this is equal to the area of the 20 States of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida, Alabama, Mississippi, and Tennessee. In his report for 1901, the governor states that the area of Alaska in acres is 369,529,600.

The journey from Seattle to the nearest point in Alaska covers no greater distance than a journey from New York to Cincinnati, and from Seattle to the most distant point in Alaska is about as far as from New York to San Francisco. The first is a two-day trip by steamer, and the latter (Seattle to Nome) requires 12 days. From Seattle to the gold fields of the Yukon, by ocean steamer, rail and well-equipped river steamer, consumes about six days.

The population of Alaska at the date of the transfer was estimated at about 30,000. One third of this number was Eskimo, located in the entire north, one third Indian, located in the south, and the last one third Russian or mixed Russian and Indian. The census of 1900 gives the population at 63,592, an increase of over 100 per cent. Of the 63,592, 30,507 were whites, 29,536 natives, 3,116 Chinese, 265 Japanese and 158 negroes. Of the 30,507 whites, 27,307 were males. It is not estimated that the population is much greater now (1905) as the Cape Nome and Yukon gold rushes have quieted down.

Industries.— Furs, fisheries, and mining (mainly gold) are the principal industries of Alaska at the present time. From the acquirement of the Territory in 1867 to 1904, inclusive, 37 years, the gross product of these industries has been: Furs, $54,000,000; fisheries, $75,000,000; mining (since 1880), $62,000,000; total, $191,000,000, or more than 26 times the $7,200,000 purchase price of the entire Territory.

Mining.— The recorded gold production began with $6,000 in 1880, reaching $9,101,000 in 1904, by the following quinquennial stages: 1880, $6,000; 1885, $300,000; 1890, $762,500; 1895, $1,615,300; 1900, $8,171,000; 1902, $8,345,000; 1904, $9,101,000.

The silver production has been small: 1890, $9,697; 1895, $86,880; 1900, $94,772; 1904, estimated, $90,000. While gold is the only mining industry in Alaska, which has so far received particular attention, there are other mineral deposits equally valuable waiting development. Large deposits of coal, some of great commercial value, exist in the Copper River Valley, and on the shores of Cook's Inlet. Valuable deposits of iron are believed to exist alongside these coal beds, while extensive copper deposits have been found in the main range of the Coast Mountains. In the Copper River extensive argentiferous quartz deposits of a promising character, have been discovered. From other regions have come rumors of mineral deposits. Putting aside these rumors and the present large annual gold production, it is easy to anticipate how very much greater will be the value of "Commercial Alaska" as soon as railways are built to open these large deposits of coal, iron, and copper, the three mineral resources, the most useful to the gigantic manufacturing interests of the American mainland.

In an address to the American Institute of Mining Engineers, at the Lake Superior meeting in September 1904, Mr. Alfred H. Brooks said: "The developments of the last five years have shown that Alaska, as a field for mining, stands in the first rank among the possessions of the United States. Its annual gold output is now about $8,000,000. It also produces silver, copper and coal in paying quantities, and its recently discovered tin and petroleum promise to become important products. Concurrent with the gradual development of this wealth, the mining public has ceased to regard the Territory simply as an Arctic province, where a few placer miners struggle with adverse conditions to secure a good stake, or a modest fortune. Of late years there has been a large influx of capital to investigate its mineral resources, but in its area of nearly 600,000 square miles there still remain large uncompleted and little known fields."

Mention must also be made of the finding of asbestos, platinum, gypsum, uranium, lead, zinc, graphite in large quantities, near Nome, and marble. The latter promises to become an important product of Alaska. Large quarries covering 400 acres are located on Prince of Wales Island. Gray marble is also found on

Ham's Island and the contiguous mainland. It is exceptionally hard and stands a test of 10,000 pounds to the square inch. The fact must also be recorded that the principal mines of lignite, anthracite, bituminous and cannel coal, found in every section of the Territory, are located on navigable streams, and near tide water, thus enabling this industry, when railroad transportation is provided, to be placed on a favorable footing as a competitor with the coal fields of British Columbia. The coal mining of Alaska is destined to be an enormous industry. In the Seattle Chamber of Commerce room, there is a lump of coal weighing 1,500 pounds. It came from Cape Sabine, in the Arctic Ocean. Ships have mined their own coal there. In his annual report for 1902, the governor of Alaska said: "One thing about the gold from Alaska that should not be forgotten is that every ounce of it is a measure of human energy and hardship, as much so as is a bushel of grain, a measure of the farmer's toil."

The report of the Senate Committee, sent to Alaska in 1903 to investigate conditions in the Territory, bears ample witness to the vast wealth of Alaska's mineral resources, subject to the provision of transportation facilities, particularly, for all minerals outside of gold, the present annual output of which is more than paying the full purchase price of the Territory each year. Incidentally, the report says: "The resources of Alaska are indicated by the fact that since the government yielded in revenues to the general government nearly $10,000,000, a sum greater by nearly $1,000,000 than the entire expenditure made in her behalf, as appears from the records of the Federal Treasury Department." In other words, Alaska is not costing the Federal government a single dollar to govern the Territory but is actually making a profit for the treasury besides paying its purchase price once each year in gold, and over a million dollars more, to say nothing of the nearly $10,000,000 a year which it sends us in furs and fish. All the Territory and all its resources to the good, without cost, and a large yearly profit earned, besides. On such a record as that, "Commercial Alaska" has a great present and the certain promise of a far greater future.

With three or four railroads crossing Alaska in different directions, men, capital, and machinery will go in and the coal, iron, copper, lead, zinc, marble, tin, and other minerals will come out, besides a far larger annual output of fish, gold, and silver. Then will go in American products and American manufactures to an amount many millions greater than the $11,108,004 worth of merchandise which we sent to Alaska in 1904.

Agriculture.— Until quite recent years, agriculture was an unknown quantity in connection with Alaska. Furs, fish, and gold absorbed the attention of employers and settlers. But since the United States Department of Agriculture sent representatives into the Territory to examine and seriously consider its agricultural possibilities public attention has been drawn to that class of Alaska's manifold resources. In this neglect to examine into the agricultural possibilities of Alaska, we have one of the many ways in which Alaska, until very late years, has not been taken seriously by the American people. Alaska is a land of more than furs, fish, and gold. It is a land where many phases of agriculture can be profitably utilized.

It is not expected or claimed that Alaska will become a great agricultural territory, but it is capable of supplying the agricultural needs of its present population, and of the population as it gradually increases.

In his report for 1899, the governor of Alaska said: "Oats, wheat, rye, varieties of barley, and buckwheat, cabbage, cauliflower, potatoes, turnips, ruta-bagas, thyme, sage, horseradish, carrots, beets, parsnips, lettuce, radishes, peas, horse-beans, onions, celery, clover, flax, rhubarb, etc., were planted, and nearly every one brought to perfection. The cereals were planted the last of April, and came to maturity with full plump grain the last of September. They grow with rank straw. Good garden truck was successfully grown as far north as Eagle City, upon the Yukon."

In each of his five annual reports since 1899, the governor of Alaska has continued to point out and emphasize the good possibilities of the lines of agriculture, specified above.

In agriculture, Alaska is eminently a poor man's country. Such can get direct and immediate returns for their own labor from adjacent consumers. Farming makes men independent. Farming will give to Alaska a class of thrifty, industrious, and self-reliant citizens — the very class of men who have made the United States what it is to-day, a nation of workers, not idlers; of doers, not dreamers; of men, not chattels.

Agricultural results in Alaska, so far, have been so small, measured in money, that a statistical record or comparison would not mean anything, and is therefore omitted. In this section of American enterprise and energy, Alaska has as yet taken only a few tottering steps. When railroads cross and recross the Territory (and some are already building) agricultural settlers will go in, small farms will be staked off and worked, crops will be raised, local wants supplied, and the surplus be shipped to Oregon, Washington, California, and British Columbia.

Manufactures.— The census of 1900 gives Alaska the following credit for manufacturing interests located in the Territory: Number of establishments, 63; capital, $3,600,409; wage-earners, average, 2,263; wages paid yearly, $1,395,709; cost of materials used yearly, $1,785,776; yearly product, $4,250,984.

We get an idea of the increase in Alaska's interest in manufactures by noting the figures of that interest, as shown by the census of 1890: Number of establishments, 10; capital, $105,727; wage-earners, average, 78; yearly wages, $18,625; cost of materials used, yearly, $30,198; yearly product, $58,440.

The increase here shown, in only ten years, is very large, being practically an increase of 98½ per cent in the yearly product. Among the 2,263 wage-earners only one woman was employed. The other 2,262 were males of at least 16 years of age.

The census of 1900 gives 1,962 as the horse-power in use in Alaskan factories — an increase of 1,511 horse-power or 335 per cent over 1890. This power was furnished by 49 steam engines, 14 water wheels, and 11 electric motors.

Food and kindred products, such as fish, canning and preserving, etc., represented $3,821,136 of the $4,250,984 total yearly product of all the

manufacturing of the Territory, which ranks fourth among the States and Territories of the Union in fish, canning and preserving.

In lumber, manufactured and unmanufactured, the census of 1900 credits Alaska with a yearly product of $429,848. Those two items make up the $4,250,984 total yearly manufacturing product of 1900.

But that is only a beginning. When Alaska has railroads, saw-mills will be built, and its vast forest wealth made use of. Mr. Petroff, an authority, says: *Forests of Alaska:* "The timber of Alaska extends over a much larger area than a great many surmise. It clothes the steep hills and mountain sides, and chokes up the valley of the Alexander Archipelago, and the contiguous mainland; it stretches, less dense, but still abundant, along that inhospitable reach of territory which extends from the head of Cross Sound to the Kenai Peninsula." The "Sitka spruce" is the universal forest tree of Alaska and is found of gigantic size on the islands of the Alexander Archipelago, and on the shores of Prince William Sound. This spruce is used in the construction of nearly every dwelling throughout the Territory. Its sappy outer portion is used as torches to light up the dark dwellings of the interior tribes, and the wood is freely used in many domestic ways. The huge planks for house-building are obtained by splitting, mostly by hand.

One of the most valuable Alaskan woods is yellow cedar. It combines, says Mr. Petroff, a fine close texture, with great hardness, durability, and a peculiar but pleasant odor. The Russians named it "dushnik" (scented wood). During the wasteful Russian occupation of Alaska, this tree, though of such great value, was nearly exterminated in the vicinity of Sitka, and on the Baranof and adjoining islands, but considerable bodies of it still exist on the British Columbian frontier on Prince of Wales Island, on Koo Island, and a few other islands of the Alexander Archipelago. In the Nass and Skeena River valleys it is also abundant.

Other Alaskan woods are hemlock and balsam fir, but not of great value, as compared with the Sitka spruce and the yellow cedar. At present lumber from Puget Sound and British Columbian mills is shipped to nearly all ports in western Alaska for the use of whites and half-breeds, while the natives in their more remote settlements obtain planks and boards by the very laborious process of splitting logs with iron or ivory wedges. Evidently the forests of Alaska have a large commercial value, which railroads will turn into money. In the meantime, we have it as a resource, against the day when the timber of Oregon and Washington becomes scarce.

Fisheries.— The fisheries of Alaska more than pay the entire $7,200,000 original cost of the Territory each year. They are of greater annual value than the annual gold field, though that also, each year, produces more than what the Territory cost. Quoting the Hon. O. P. Austin, chief of the Bureau of Statistics again, we find that in 1901 the Territory packed and shipped 2,029,269 cases of 48 one-pound cans each, and 18,942 barrels, composing in all 100,-000,000 pounds of salmon, taken from Alaska waters in one year.

To produce this result required 30 companies and individual packers, occupying 55 canneries, and 12 salteries and using 31,000,000 salmon. The capitalization of these enterprises was $22,000,000, and the value of the plants, including vessels, was $12,000,000. All this has grown from two establishments in 1881, producing 13,000 cases a year, of the value of $50,000. The value of the salmon pack in 1901 was $7,075,000. These figures show an increase in the yearly product of 14,000 per cent or 140 fold in the short space of 20 years. The annual packs of salmon since 1901 have been: 1902, $7,834,000; 1903, $8,606,000; 1904, $0.-054,000; while the annual breed of salmon does not lessen, but the contrary. This is a case where we do not have to buy the raw material. It is a nature's free gift to us each year, just as is gold and everything else we get out of the ground. In this reflection we strike the keynote of the marvelous prosperity of the United States — its boundless natural resources. But salmon is not the only fish which Alaska produces. The codfishing industry is also worth $150,000 a year. The area in which the cod may be taken and the supply justify the statement that the cod fisheries of Alaska are destined to exceed in value those of Newfoundland, or any other part of the world. As a safe calculation, there is not less than 125,000 square miles of codfishing in connection with the Alaska coast. Then there are Atka or Attu mackerel, black cod, halibut, and herring. The salmon industry employs about 13,000 persons, including 5,000 Chinamen and 2,500 natives. The yearly pay roll amounts to about $2,700,000. The tin plate used costs $1,150,000. This disbursement of more than a million dollars for tin cans is a noteworthy fact. In 1901, the shipping employed was 110 steamers, 55 sailing vessels, and 1,777 lighters and boats, a very imposing fleet.

The government tax of 4 cents a case and 10 cents a barrel yields about $100,000 a year. The salmon pack of Alaska fills about one half the yearly requirement of the United States. In 1902 the Pacific coast pack was worth $4,259,000. As the two packs combined fill only 75 per cent of the American demand, and as that demand grows with the rapid increase in population, and further, as salmon are heavy breeders, it is evident that the salmon industry of Alaska as well as that of the Pacific coast has a growing future. That part of "Commercial Alaska," as well as the gold part, is an immediate and continuously profitable proposition.

Fur Seals.—The Pribilof Islands are the seat of the fur seals industry of Alaska. They came to us in the purchase from Russia. They are leased to the North American Commercial Company by the United States Government for an annual rental of $60,000 and a tax upon each skin taken of $10.22½. The number of seals to be killed each year being fixed by regulation of the secretary of the treasury. In the years 1870–1902, the lessees have taken 2,209,621 seals.

No official statements of the value of the seal skins taken on the Probilof Islands are made. Mr. Petroff, the agent of the United States Census in 1890, estimated the value of seal skins taken in Alaska from 1867 to 1890, at $31,537,592. This estimate, combined with estimates from official sources since justifies an allowance of $50,000,000 as the value of the seal skins, taken from the purchase of the Territory to the present date. The sea otter and

others bring the total for furs up to $54,000,000.

Education and Churches.— The entire educational work in Alaska, except in the incorporated towns, is under the control of the Rev. Sheldon Jackson, D.D., United States General Agency of Education in the Territory. His report for 1904 shows 35 public schools, 38 teachers, and 2,257 pupils outside of the schools in towns. Nineteen of the new schools were established in 1904. The expenses are $56,211.

The Presbyterian Church supports 14 missions and a hospital and training school. The Protestant Episcopal Church has 10 missions, and the Catholic and other religious organizations a smaller number.

All this is education, and it has a direct bearing on the present and future of Commercial Alaska.

Transportation.— Transportation in Alaska, while not to-day the problem it was a few years ago, is still the "question of the hour" and the fundamental necessity and prime requisite of commercial or other success in the Territory. In the summer there is one boat of 1,000 tons each day for the ocean travel from Puget Sound to Skagway. One can now go by rail from Skagway to White Horse, over the mountains, and freight rates are only one tenth of what they were before the railroad was built. In the summer season the ardent adventurers can go by semi-weekly steamers from White Horse to Dawson. In the winter the trip has to be made by stage. Lodging houses along the road charge about $6 a day for meals and lodging. In the summer the $75 boat fare includes meals. The steamboats on the Yukon River are modern and well equipped. Nome is reached by steamer from Sitka to Unalaska in the Aleutian chain of islands, and thence north to Saint Michael and Nome.

Something is being done for transportation, through sundry small appropriations in the army bill, toward building wagon roads and trails. Says the governor: "Trails are better than nothing. If Congress cannot bring itself to aid us to railroads, then we shall be grateful for wagon roads, and if they are impossible let us have trails; but the railroads are bound to be built. The American spirit animates the movement. Governor Gilpin's dream of a 'cosmopolitan railway' will be realized."

Postal Service.— Just as fast as Alaska needs and can take care of post-offices, they are being started. Daily mails leave the Pacific coast for Alaska. The present number of post-offices is about 80, and mails are regularly delivered north of the Arctic Circle.

Telegraphs.— The United States and the world now has telegraphic communication with all the chief centres of population in Alaska. This work has been done by the signal office of the War Department. The lines also connect with those of the Canadian telegraph system, and with all the telegraph systems of the United States.

A military cable, 1,300 miles long, connects Seattle with Juneau and Sitka, affording an alternate route (the Canadian is the other) for commercial business and a more direct and satisfactory means of telegraphic communication for the government.

Land Laws.— The law recently enacted by Congress permits the application of the homestead laws of the United States to tracts not exceeding 80 acres. Owing to the lack of surveys very few homesteads have yet been applied for under this act. But they will when Alaska has railroads, because railroads involve surveys, and emigration from one point to another always follows the whistle of the locomotive.

Commerce.— The commerce of Alaska is a substantial and growing quantity. Beginning with nothing less than a generation ago, it has already reached satisfactory proportions. It is not necessary to trace at length the history of Alaskan commerce from the acquirement of the Territory, as for quite a number of years after that act of farsighted statesmanship Alaska was only thought of as the place from whence the seal skins of our wives, our daughters, and our sweethearts came. It is a vastly different proposition to-day, with the acquirement of Hawaii and the Philippines, the American Pacific cable in operation, the American Panama Canal in sight, and the Alaskan boundary dispute settled in our favor. Commerce between the United States and Alaska means something these days, and the commerce of Alaska with Canada and the Far East is beginning to tell.

A few figures will tell the story.

	From the U. S.	From Other Countries.	Total.
1879	$ 317,000	$ 4,791	
1890	1,897,000	24,577	
1895	3,017,000	55,080	
1903	9,509,701	477,463	$ 9,987,164
1904	10,165,110	667,355	10,772,465
1905 (est.)	11,000,000	800,000	11,800,000

Alaskan Exports to all Countries.

1879	$50,378
1890	4,682
1895	11,520

	To the U. S.	To Other Countries.	Total.
1903	$10,228,569	$1,612,128	$11,840,697
1904	10,165,140	1,565,690	11,730,830
1905 (est.)	11,000,000	1,700,000	12,700,000

These export figures are exclusive of the Canadian dug gold — about $10,000,000 a year, which reaches the United States through Alaska.

Summary for 1904, actual:

Alaskan imports	$10,772,465
Alaskan exports	11,840,697
Canadian gold	10,000,000
Total commerce	$32,613,162

Summary for 1905, estimated:

Alaskan imports	$11,800,000
Alaskan exports	12,700,000
Canadian gold	10,000,000
Total commerce	$34,500,000

This is the concrete result of 38 years of American "Commercial Alaska." Nothing to begin with, practically nothing for 27 years after the beginning (only $3,000,000 in 1895), then a growth to $30,000,000 more a year in nine years. Almost an average growth of $1,000,000 a year, for each of the 38 years life of American "Commercial Alaska," with 27 of those 38 years practically dormant.

WALTER J. BALLARD.

Alaska, Recent Development of. No longer is Alaska, even in popular conception, the lone land of ice and snows which fiction and tradition long presented it. Northward, swift on the

heels of the gold-seeking pioneers, have gone railroad builders and telegraph linemen, engineers, capitalists, bankers, teachers, and settlers, until not only Alaska but the whole vast stretch of the Far Northwest is repeating California's marvelous story of development. Steamers, many of them palatial in their fittings, now navigate the Alaskan rivers; towns with organized systems of government are growing fast, with schools and banks and churches, and streets lighted by electricity, and paved. The telegraph and the telephone connect the principal settlements, and railroads are being built which in a year or two will traverse the peninsula almost from end to end.

Yet the new Alaska, which has become so important a reality, is, in a measure, but a startling revival of the commercial Alaska of 60 years ago. Then Sitka—a thousand miles north from Seattle Washington — was the industrial capital of the Pacific coast of America, and San Francisco but a gathering place for indolent rancheros, who bought their plowshares, hoes and hatchets from the industrious workmen of the Far North. From the shipyards of Sitka went forth the first steamships built on the Pacific, and the bells which will chime from many a Catholic mission-house were cast there. No better equipped naval station existed than that at the Alaskan capital, nor busier brass and iron foundries and machine-shops. The California "Forty-Niner" worked with a pick and shovel made at Sitka; the woolen-stuff clothing which he wore came from Sitka; the salt fish he ate and the lumber with which he built were also the product of far-away Alaska, carried in Sitkan-built vessels, manned by Sitka sailors.

But the military managers of the Russian-American Company were not captains of industry. Vast sums were squandered in impracticable experiments, in mining valueless coal, in extracting iron from inferior ore, in making bricks and woodenware for which no market existed. Thus the trade of Sitka languished, and in time the catching of fish and furs became the only occupation of the Alaskans. Even the purchase of the country by the United States failed for many years to add a stimulus to its lapsed industry.

The new North which has arisen may not again dominate the trade of the Pacific Coast, but it has attained an intrinsic importance of which the Russian owners of Alaska never dreamed, not merely through its wealth of minerals, its furs, and its fisheries, but also in considerable measure through its possibilities in agriculture. Fields of grain and gardens stocked with every variety of vegetable are now familiar sights on the outskirts of a hundred thriving settlements. From end to end of the Yukon, one of the mighty rivers of the world, the traveler may wander during four months of the year and never see snow. Instead, there will be a tangle of rich vegetation, of great forests, of grass that grows as high as a man's shoulder, and endless fields of beautiful plant life. Wild berries in great variety — raspberries, currants, huckleberries, blackberries, cranberries, etc.— beautiful ferns waving in the soft breezes, great beds of the purple lupine and the red columbine, wild celery and wild parsnip growing many feet high, ponds on which float great yellow lilies, with the purple iris bordering their banks, are everywhere.

When Alaska was purchased by the United States in 1867 its value was lightly regarded. The price paid — $7,000,000 — was thought to be excessive, and there was much popular opposition to the terms. Yet in 36 years the government received in revenues not only the sum expended, but $2,000,000 more. During the same period Alaska and the adjoining Canadian Yukon territory have supplied fish, furs, and mine products amounting in value, at a conservative estimate, to $375,000,000. Goods worth about $40,000,000 a year are now sent in return, and the amount of capital invested there is probably not less than $125,000,000.

Of the future of the new North, President Roosevelt, addressing an audience at Seattle, Washington, in 1903, made this significant prophecy:

"The men of my age who are in this great audience will not be old men before they see one of the greatest and most populous States of the entire Union in Alaska. . . . I predict that Alaska, within the next century, will support as large a population as does the entire Scandinavian peninsula of Europe, the people of which by their brains and energies have left their mark on the face of Europe. I predict that you will see Alaska, with her enormous resources of mineral, her fisheries, and her possibilities that almost exceed belief, produce as hardy and vigorous a race as any part of America."

Not only Alaska, but the entire northwestern portion of the continent — for many hundred miles beyond the international boundary — is undergoing a marvelous development. Ten thousand miles of railroad are already under construction or definitely projected in territory farther north than is now touched by any existing completed line; a greater mileage than that of the Union Pacific, the Northern Pacific, and the Erie systems combined.

A glance at the line in the accompanying map which marks the northern limit of cereal production in America will indicate a reason for this railroad construction. Gold and furs alone could not have brought it about. Were the great western North the bleak counterpart of "pitiless Labrador" the miner and hunter there would still pack their treasures of mineral and fur over weary wastes of snow by dog train. But, whereas in the East the extreme limit of cereal-growing territory is reached in latitude 49°, at a point a little north of Rimouski, on the St. Lawrence River, in the West the limit is Norton Sound, beyond St. Michael's, more than twelve hundred miles nearer the pole. So far north as that are grains now grown.

As long as the States to the south are still undeveloped, the north received but scanty attention. At intervals, it is true, had come reports of great natural wealth which existed there, and now and then the outcropping of a boundary dispute had lent ephemeral interest to the country. But the gold finds of 1896 in the Canadian Yukon and of 1898 near Nome came when the western States were beginning to be filled up. Thousands of American farmers had already moved northward into the Canadian provinces of Manitoba, Assiniboia, and Alberta, beginning a movement which has since assumed enormous proportions. The gold thus hastened a natural development. Prevailing fallacies regarding the climate of the new land disappeared.

In southern Alaska, which is tempered by the warming airs from the Japan current, the thermometer rarely falls to zero, and the changes from midwinter to midsummer do not exceed twenty-five degrees. Even at St. Michael's north of the mouth of the Yukon River, the mean summer temperature is 50° F. In the interior the climate is more severe, but not so bitter as is commonly believed. Daily observations during five summers in the Klondike region show that on the average the temperature there rises to 70° or higher on forty-six days, and to 80° on fourteen days; 90° was recorded in Dawson in June, 1900, and 95° in July of the same year.

Great hardships were undergone by the gold miners during the pioneer period, but these were due to abnormal conditions. The gold fever had carried a great swarm of fortune hunters into an unknown country of vast distances. Confusion, suffering, and even starvation were the natural outcome. An incident in the construction of the White Pass and Yukon Railway well illustrates the conditions which then prevailed. On the morning of one June day in 1899 there were 2,000 men at work along the line of the new road — doctors, lawyers, teachers, and college men, in a motley crowd with Chinese laborers, and rough prospectors who could not write their names. That afternoon came the news of a big discovery of gold near Atlin, and in the evening there were but 600 men in camp. The other 1,400 had plunged into the wilderness, carrying with them the company's picks and shovels, but leaving behind a half week's pay at ten dollars a day. Such was the spirit of recklessness in which the gold-seekers invaded the new country.

Scenes similar to those which marked the rush to the Klondike were repeated at Nome. The latter place is without a natural harbor, and passengers and supplies had to be landed through the surf. In the months of June and July this is accomplished with little difficulty, but later in the season storms prevail, and the landing is then attended with considerable peril. Vessels are forced to anchor from half a mile to two miles from the shallow beach, and their cargoes removed in lighters, which were frequently lost in the surf. Wrecks of schooners, barges, steam-launches, boats, and stern-wheel steamers littered the beach at Nome every year, and pumps, donkey boilers and engines, dredging machinery and damaged provisions were strewn along the shore.

The first discovery of gold at Nome was made by a United States soldier who was digging a well, and the first to profit by it was an old prospector from Idaho, who was ill and not able to reach the gulches farther inland. In twenty days the man from Idaho took out three thousand dollars' worth of gold with a rocker. With the news of the find a wild frenzy to dig in the beach seized people everywhere, and during the height of the excitement nearly two thousand men were burrowing like moles in the sand. Every man at Nome — physician, lawyer, carpenter, clerk, or whatever else his vocation— abandoned his ordinary work and took up the shovel and rocker. The price of labor went up to fifteen dollars a day, but even at that rate working hands were hard to secure. When the army of miners stopped work in the fall the beach for fifteen miles presented a hugh rampart of piled-up sand, giving to the city the appearance of having been fortified against invasion.

Nome is now a city of 25,000 population, and the building of two new railroads, which are under way, and the improvement of the harbors at Port Clarence and at Solomon, will remove the last of the transportation difficulties of its inhabitants. In the past the only means of forwarding freight from the city to interior points not reached by the Yukon River steamers was by men wading in the shallow streams and pushing flat-bottomed boats ahead of them. The cost was about $300 a ton for fifty miles, and from 8 to 15 days were required to make that distance, according to the conditions of the weather.

Nome is the western terminus of the railroad development of northwestern Alaska, whose roads are the farthest north of all in the world, extending almost within the Arctic Circle. The city is about 250 miles southeast of Cape Prince of Wales, the point at which Alaska most nearly approaches Asia, and is reached by steamers from the western coast of the United States by passing through the Aleutian chain, past Unalaska, as well as by rail from Skagway and steamboat down the Yukon River. Nome boasts good hotels, large stores, daily newspapers, banks, electric lights, telegraph and telephone systems, and the other usual adjuncts of civilization in more southern climes. It is connected with St. Michael's by cable, and by telegraph with Dawson and Skagway. Handsome private residences are being built by men who have made their money there and who have settled down to make the city their home. Well-kept lawns and flower gardens add to the wonderful metamorphosis which has overtaken the sandy beach.

Seward Peninsula, on which Nome is situated, is being rapidly "gridironed" by the various railroads built to communicate with the principal gold mines and with the other towns in that part of Alaska. The Valdez Copper River & Yukon Railway will run from Valdez, the most northerly port in Alaska, to Eagle City, a distance of 430 miles, and will open up the mineral and agricultural districts of the Copper, Tananá, and Yukon valleys. Construction has already begun on this line, the route lying through a country which is heavily timbered, with tributary territory rich in gold, copper, and coal. With a railroad projected, as a part of the Grand Trunk Pacific System, from Port Simpson to Dawson, with a 100-mile line soon to be built from Dawson north, and with the Valdez Copper River & Yukon Railway coming east to Eagle City and west to connect with the Nome & Solomon City Railroad, it remains but a question of time when there will be all-rail communication from New York to Norton Sound, a few miles across Bering Strait from the continent of Asia. A northern spur from the Trans-Siberian Railway would then realize the once lightly regarded dream of "New York to Paris by rail."

The first railroad undertaking in the Far North was begun in southern Alaska and the British Yukon in 1898. In June of that year work was begun by a syndicate of English capitalists on what is now the White Pass & Yukon Railway, extending from Skagway, in Alaska, to White Horse, Yukon Territory, a distance of 112 miles. It was constructed pri-

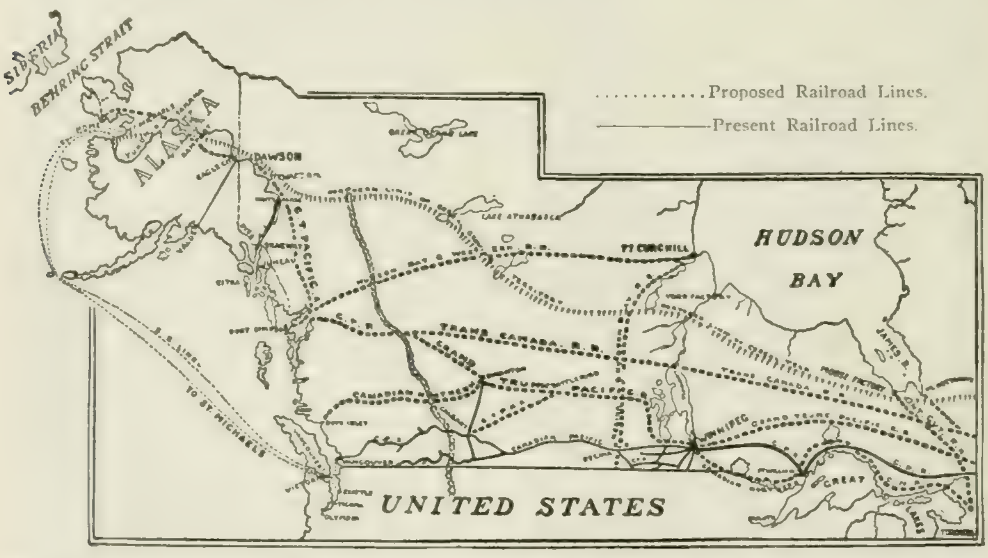
marily to afford access to the gold fields of the Canadian Yukon, but has since been made a link in the continuous rail and river route to northwestern Alaska and Seward Peninsula. The road was completed to White Horse in June, 1900, at places the cost of construction exceeding $250,000 a mile. The route had been used for pack-horses in the fall of 1897, but the trail was almost impassable, and immense numbers of the animals had died in their tracks. Two thousand had to be collected and burned with kerosene before the work could be undertaken. In attempting to lower Lake St. Louis about three feet, the entire lake washed away, causing widespread damage. The total cost of the White Pass Railroad was about $5,000,000; but it paid nearly $2,000,000 profits during its first two years' operations.

From White Horse to Dawson — which has a population of 1,200 — a distance of 482 miles, connection is now made by modern steamers in summer and by four-horse sleighs in winter. The stages used in winter cover the distance, under ordinary conditions of weather, in three and a half days, or at a rate of about 90 miles a day. A railroad was built last summer from West Dawson to Stewart River, a distance of 82 miles, tapping the rich mining districts in that direction. A number of other railroads leading to different gold centres are now being constructed, and in a few years Dawson will be connected with its outlying districts in every direction, and even, it is projected, with the transcontinental lines to the south.

Dawson enjoys almost as many municipal advantages as any place of its size in the United States. It has a splendid system of water-works, a local telephone system and long-distance connections with the principal mines, telegraphic communication with the world, churches of every denomination, large Federal and municipal buildings, and good schools. There are a number of clubs and lodges, as well as theatres and other places of amusement, and three banks. The personal and realty assessment of the city exceeded $11,000,000 last year, and post-office orders to the value of $1,800,500 were sold. The streets are all thoroughly lighted by electricity. Lines of steamboats along the wharves, loading and unloading, and steam dredges at work in the river, give an animated aspect to the water-front. More than $5,000,000 is about to be spent by a private company in installing a huge water-supply and pumping plant to furnish water for consumption and for mining purposes, in working the deposits that line the side-bars of the neighboring streams.

Three years ago the inhabitants of Dawson lived principally on dried and canned meats and German sliced evaporated potatoes. To-day fresh meat is brought in, frozen in winter and in refrigerator cars to White Horse in summer, and all vegetables are grown in market gardens nearby. Nothing pleases the Dawson citizen more than to entertain a skeptical visitor from the south at table with lettuce, asparagus, green peas, or celery, cauliflower, cabbage, and carrots, according to the season, grown in his own rear yard; and the same civic pride has led the Dawson Chamber of Commerce to display some very fine specimens of barley and oats grown in that section. Moreover, throughout the Klondike country live stock can find sufficient feed to sustain life outdoors even in winter.

From Dawson to St. Michael's, by the Yukon River, is 1,600 miles, and during the open season of navigation — from the middle of May till the middle of October — about 40 stern-wheel steamboats run between the two points in from 9 to 12 days. The Yukon is easy to navigate, being without snags and with shores alongside of which boats can run and tie up at almost any desired spot. Between its mouth and the Tananâ it flows with an easy current of about three miles an hour, the stream varying in width from a mile to a mile and a half. The rest of



The great Northwest and its projected transportation facilities, showing also the northern limit of cereal growth.

the river, below Dawson, flows variously through mountainous regions and wide flats, attaining at places a width of 10 miles, with many channels and numerous small islands.

The winter trade begins as soon as the ice has formed in sufficient thickness to sustain teams of dogs and loaded sleighs, and continues until the break-up in the spring. The trail having once been marked by some venturesome first traveler, running as nearly as possible over the smooth ice near the shore, is generally followed thereafter. Although the temperature sometimes falls to 50 degrees below zero, such occasions are rare, and even then the air is dry and uniform and accompanied by little wind. At no part of the route is the traveler out of telegraphic communication with the world.

At Eagle, the first American town beyond Dawson, four large trading companies maintain well-stocked stores, and Fort Egbert, located there, has a garrison of 200 soldiers, with barracks, stables, hospital, and officers' houses. There are two saw-mills, and the town is the headquarters of the United States Weather Service for the interior of Alaska. Several large gardens supply an abundance of vegetables — potatoes, carrots, peas, beans, lettuce, radishes, cauliflower, etc.— and barley and oats are raised in steadily increasing quantities. Grass grows luxuriantly from the fertile soil, and there are large natural meadows in the vicinity from which heavy crops are cut. Mowing machines and other hay-making tools are frequent sights along the bank of the river all the way to St. Michael's.

The railroads of Alaska and of the Canadian Yukon are being built primarily because of the enormous mineral wealth to be tapped. Those projected for the Hudson Bay, North Saskatchewan and Peace River districts have another reason for their inception. Agriculture and lumber are the great natural resources of that vast stretch of little-known territory, and minerals and furs play but subordinate parts.

Almost a thousand miles north of the boundary between the United States and the Canadian Northwest territories, in the valley of the Peace River, wheat, barley, and oats are grown in quantities limited only by the number of agriculturists; and a 100-barrel roller-process flour-mill, the most northerly mill on the continent, has just been completed at Vermilion. Two other water-power stone mills, owned respectively by a private firm and by the Roman Catholic mission, have been running for the past two years, and have been offered more grain than they have been able to handle. Two steam saw-mills are also in continuous operation, while cattle and hogs are raised by the settlers and find a ready market among the traders. The town is lighted by electricity, derived from the water-power of Vermilion Falls.

The wheat which was awarded the first prize at the Centennial Exhibition at Philadelphia in 1876 came from the Peace River country. Farther east, on the south side of Lesser Slave Lake, a wild meadow, 30 to 40 miles in extent, from which three tons of grass to the acre are obtained, gives evidence of the richness of the soil there, while the land on the opposite side is excellently adapted to mixed farming, consisting of open prairie interspersed with tracts of cottonwood timber. Dr. Dawson, of the Canadian Geological Survey, estimates the Peace River country to contain 15,140,000 acres of good arable soil.

The Hudson Bay and Western Railway, the bill incorporating which was passed at the last session of the Canadian Parliament, will connect Port Simpson, on the Pacific, with Fort Churchill, on Hudson Bay, a distance of 1,500 miles, passing through Vermilion and running south of Lake Athabasca and north of Reindeer Lake. Athabasca Lake is connected with Great Slave Lake by the Slave River, and, with the exception of a break about 20 miles long, steamboat navigation between the two is uninterrupted. From Great Slave Lake the Mackenzie River affords a clear course to the Arctic Ocean. For years past steamboats have been plying on the Athabasca and the Mackenzie, and with the Hudson Bay and Western Railway completed it will be possible for a passenger to buy his ticket in New York — or in any other city, for that matter — for the Arctic Ocean, and proceed there with almost as great comfort as if he were booked for the Adirondacks.

Still another railroad — running from North Dakota — will have Fort Churchill as its northeastern terminus. The bill incorporating the construction company was passed by the Canadian Parliament at its last session. Apart from agriculture, the southeastern Hudson Bay district is said to be rich in minerals of all kinds. The fisheries of the bay are also valuable, and whalers from New Bedford even now find it profitable to go there, notwithstanding that it takes them two years to make a catch. Cod, trout, and whitefish in large numbers are found in both Hudson and James Bay. At Moose Factory there are several large gardens, in which all kinds of vegetables and fruits are grown, and cattle find excellent pasturage on the natural meadows, where the wild grass grows in great luxuriance.

The timber wealth of all this section is naturally great, the forests of spruce, pine, and poplar having as yet been scarcely touched by the axe of the woodsman. Unrivaled water-power is furnished by the innumerable streams and rivers, and the transportation of sawn lumber is counted upon to furnish no inconsiderable source of revenue to the railroads. A species of large poplar called "liard," or balm of Gilead, which is much sought for by cabinet-makers, is said to grow very extensively in the Mackenzie Valley, and tamarack for railway construction is found in the entire region. The greater part of the territory, also, is the natural home of pulp-wood, where, it is declared, is a perennial crop to be harvested unsurpassed in the world. The average annual snowfall at Moose Factory, taken for a period of five years, is 80 inches, as compared with 177 inches during the same period at Montreal.

But railroads are only one phase of the increasing activity in the North. The telegraph has far outdistanced the iron horse, and remote corners, as yet long distances removed from any line of railroad, can flash their intelligence around the world. Since 1901 the Signal Corps of the United States Army has put in working order in Alaska more than 1,500 miles of land telegraph lines and submarine cables, and in the Canadian territories of the Yukon and North British Columbia the Dominion Government has

displayed an equal activity. About 2,000 miles of Canadian Government telegraph lines have been built from the international boundary, beyond Dawson, south to Port Simpson and Quesnelle. At the latter point connection is made with the regular commercial lines. Well-equipped telephone services have also been established between the towns, and scarcely a place of 500 inhabitants in the mining country has not its local and long-distance telephone system.

On the Pacific Coast daily mails leave by all the principal steamship lines, and are forwarded from Sitka, Skagway, Nome, and other distributing points by steamer, rail, wagon, and carrier. Where ordinary means of distribution fail, the Russian reindeer, domesticated in Alaska, carry the sacks over the frozen lakes and snow-mantled uplands, traversing a vast distance in an incredibly short time. The highest salaried postal official in the world is in Alaska. He receives $25,000 a year for carrying the mail, twice a month the year around, to Fort Yukon, providing his own dogs and sleds for the purpose. There are now upward of 100 post-offices in Alaska, and mails are delivered regularly beyond the Arctic Circle.

The development of Alaskan oil-fields promises to establish an industry the extent of which cannot be yet foretold. In 1902 an immense oil gusher — Alaska's first — was struck at Cotella, near Kayak, 30 miles south from Copper City. Oil was thrown 150 feet into the air, carrying away everything in its course and being capped with great difficulty. Experts were at once sent to the scene by the officials of the Standard Oil Company, but a Canadian and English syndicate had acted more quickly; and secured control of the larger part of the Kayak fields, comprising 40,000 acres of land which had been leased to the Alaska Development Company. The British capitalists chartered two steamships to convey north from Tacoma, Wash., a great quantity of pipes and machinery obtained from Pittsburg, Pa., together with other supplies. A hundred men were employed in sinking additional wells, and $500,000 was to be spent in development work, including the erection of an experimental refinery.

The fisheries of Alaska are among the richest in the world. Cod, halibut, and other important deep-sea fishes are found in the waters off the coast, and salmon in all the streams. More than half the entire salmon product of the United States comes from Alaskan waters. It is the opinion of competent authorities that the cod banks exceed in wealth those of Newfoundland. The cod industry, however, is as yet only in its infancy — if, indeed, it can be said to have attained even that primitive stage of development. There are about 15,000 persons engaged in the salmon fisheries, and the market value of last season's output was a little more than $7,000,000, which is exactly what we paid for Alaska. The packing industry is conducted at 60 canneries and 15 salteries. The total number of salmon of all varieties taken in 1902 was about 33,000,000. The companies engaged in this industry have a capitalization of about $25,000,000, and their plants, including vessels, are valued at $15,000,000. The amount which they pay in wages exceeds $2,500,000 annually, and the yearly expenditure for tin plate is about $1,100,000. In the shipping of the fisheries last year there were employed 115 steamers, 57 sailing vessels, and 100 boats and lighters. The codfishing firms permanently located in Alaska have vessels, plying only in Alaska, valued at $60,000. According to estimates of the United States Fish Commission, there are not less than 125,000 miles of codfishing along the Alaskan coast.

The special features of Alaska — its furs, fisheries, and gold mines — have been so frequently exploited by writers that an entirely erroneous idea has been conveyed as to the country's other diversified sources of wealth. That a grain-growing soil could be found so far north, with summers sufficiently long to bring wheat to maturity, has not been supposed possible. Yet, as I have already said, not only has wheat been grown and successfully harvested wherever the experiment has been made, but even so far north as Fort Yukon, within the Arctic Circle, oats, rye, and barley are now grown regularly. The winters of Alaska are more hospitable than those of the great plains of Wyoming, Montana, and some parts of Nevada, and in the dead of winter horses and cattle can be worked without fear of being frozen. The temperature frequently is very cold, but there are no storms.

Except on the coast of Bering Sea, all the hardy vegetables are grown with marked success throughout Alaska and the Canadian Yukon south of the Arctic Circle. No finer potatoes, cauliflower, cabbage, kale, peas, lettuce, and radishes could be found anywhere in the United States than samples which I have seen grown at the government experiment stations at Sitka and Kenai, and I have been told by a friend that at Holy Cross Mission he had eaten new potatoes, cauliflower, and other late vegetables in the month of July. At Rampart, in latitude 65°, winter rye, seeded there in August, lived through the winter perfectly, and matured grain by August of the following year. Barley seeded in May was ripe by the middle of August.

The great river valleys of Alaska and the Canadian North embrace cultivable areas large enough to form several good-sized States. All through the interior, in fact, there are to be found extensive tracts of grass lands, the growths from which, could there be found a market for them, would exceed in value the products of all the gold mines. Along the route surveyed for the Valdez Copper River & Yukon Railway, from Valdez to Eagle City, many large meadows, on which the grass was waving waist high, were traversed by the party of engineers. A number of horses were seen which had run at large in this region for two years.

Stock-raising is becoming an important Alaskan industry — within a very few years it is probable that regular shipments of cattle for export will be made. The extensive areas of rich growths of grass and the absence of storms in the winter make many sections of the country ideal places for ranching. The present summer is seeing an important step being taken in this connection. Several large stock-growers of Washington State are planning to convert the Aleutian Islands into vast cattle and sheep ranges, which will surpass in extent the rapidly diminishing ranges of Montana and Texas. One company has already begun the shipment of 25,000 sheep and 5,000 head of cattle to the Aleutians, a first consignment of 8,000 head of

sheep having recently been sent from San Francisco. The company had previously demonstrated that sheep will thrive there, living throughout the winter solely on the grass of the islands, by having landed 1,000 head there about a year and a half ago.

The rapidly increasing importance of the North has made the United States government decide to establish a coaling station at Dutch Harbor (q.v.), the present end of the cable from Seattle.

In 1892 the total foreign trade of Alaska — by which is meant imports and exports of merchandise — amounted to but $28,366, of which the larger part were imports. In 1900 the total trade was little less than $1,000,000. For the fiscal year ending 30 June 1903, Alaska's foreign trade reached a total of more than $22,000,000, of which the exports were about $13,000,000. With the gold and silver added, the exports would have exceeded $26,000,000, making the total foreign trade $35,000,000. The importation of iron and steel products into the Territory during the year exceeded in value $2,000,000.

And yet the development of the North has only begun. Its immense wealth of fisheries and of timber has been but little exploited; its possibilities for agriculture have not even been attempted. Only the industry in furs and its gold mines have received general recognition. When the cod banks of the coast have been exploited; the salmon industry placed on a more systematic basis; the deposits of gold, iron, nickel, copper, and coal worked by adequate modern machinery; the vast tracts of fertile land brought under cultivation, and the railroads briefly indicated in the foregoing sketch have been completed, the great North will be no longer the lone *terra incognita of* the past, but will throb with an active and productive civilization.

In the steady stream of population northward there is nothing known of the limits of nationality. There are more of American birth in Dawson than there are Canadians. Even in the great wheat lands of Manitoba the farmers from Dakota, Montana, and the other States of the North and West almost equal in numbers those of Canadian origin. The explanation is simple. With its population of 90,000,000 the United States can send forth its pioneers in the ratio of thirteen to one from the provinces of the Dominion. Loyalty to British connection will not prevent the spread of American influence and the growth of American ideals of government. The entire Canadian Northwest is already more American than British in its administrative systems.

Shut off, industrially, from the east of Canada by the uninhabited and not very cultivable strip north of Lake Superior and Georgian Bay, northwestern Canada must make its commerce with the northwestern States and with Alaska. From south, west, and north, therefore, the influences will be wholly American, while within its boundaries American capital and American settlers will spread the leaven of the genius of American institutions. A few years ago it was the custom to laugh at the purchase of Alaska as having been, somewhat politely, forced upon the United States by Russia as a return for her supposed friendship during the Civil War. The laugh is no longer appropriate. Larger in area than the combined States of Alabama, Connecticut, Delaware, Indiana, Indian Territory, Kentucky, Louisiana, Maine, Maryland, Mississippi, Rhode Island, New Jersey, New York, Pennsylvania, South Carolina, Tennessee, Vermont, Virginia, and West Virginia, or than the British Isles, France, Germany, Portugal, and Belgium together. Alaska, already an important part of the United States, will contribute largely to a social and commercial, if not a political, union of two nations.

William R. Stewart.
Editorial Staff 'New York Daily News.'

Alaskan Boundary Commission, a mixed tribunal which met in London, England, 3 Sept. 1903 to arbitrate on the contentions of the Canadian government with regard to the boundary line between Alaska and Canada, from Mount St. Elias to the Portland Canal. The commission consisted of three Americans and three Britons, the American commissioners being Secretary Root, Senators Lodge and Turner, while the British commissioners were Lord Alverstone (formery Sir Richard Webster), English, Sir Louis Jetté, and Mr. A. B. Aylesworth, Canadians. Ex-Secretary Foster was agent for the American government and Mr. Clifford Sifton for the British government.

In May 1898 the United States and Great Britain agreed to appoint an Anglo-American Joint High Commission to consider and put on a satisfactory basis the regulations of the North Atlantic fisheries, commercial reciprocity, the Bering Sea fishery question, and other disputes which disturbed relations between the United States and Canada. When the questions for the deliberation of this commission were fixed, no mention was made by Great Britain of any divergence of opinion regarding the Alaskan boundary.— but on 1 Aug. 1898 the British government informed the United States that a difference of views existed as to the provisions of the treaty of 1825, which defined the Anglo-Russian boundary. On 23 August Great Britain submitted its claims, enumerated below. It was proposed to arbitrate the matter, but the High Joint Commission could not agree. The United States rejected a European umpire for American territory and the Canadians would not agree to an American judge. The final compromise was the above-mentioned tribunal.

Previous to the discovery of gold in the Yukon region there was no dispute, or occasion for dispute, as to the course of the boundary line defined by the Anglo-Russian treaty of 1825. For 73 years it had been tacitly recognized by all nations, including Great Britain. The history of that treaty is interesting. The government of the czar had from time to time by ukase asserted exclusive jurisdiction over the coast lands and the waters of Alaska, to prevent any encroachment by the British Hudson's Bay Company upon the monopoly of the Russian-American Fur Company which had established its stations and carried on its trade in the islands and along the coast of Alaska extending northward from the Portland Canal. Disputes arose, and in the attempt to settle them the negotiations were begun which led to the signing of the treaty of 1825. The purpose of Russia in that negotiation was altogether to shut out Great Britain from the coast and the waters in which the Russian company was carrying on its business. The attempt of Great Britain was to secure a foothold upon the coast with the obvious

purpose of getting an opportunity for the Hudson's Bay Company to establish its stations there, which was the very thing Russia sought to prevent.

The negotiations lasted from 1822 to 1825, Count Nesselbrode and M. de Poletica conducting the Russian case, and Sir Charles Bagot first, and Lord Stratford de Redcliffe finally, the British case. At that time Great Britain feared that the United States would insist upon retaining possession of the whole Oregon territory up to the Russian line at the historic parallel of 50° 40'. This would have shut off Canada from the Pacific coast entirely, and the British, therefore, made strenuous efforts to get an outlet through the Russian coast strip, making various propositions, one after the other which the Russians rejected, stubbornly adhering to their original proposition, which in the end prevailed.

The British first asked to have the boundary line drawn straight down the 141st meridian to the sea at Mount St. Elias, thus depriving Russia of the entire "panhandle" of Alaska, and causing her even to relinquish Sitka, the colonial capital. This was peremptorily rejected by Russia without serious consideration. The British next proposed Christian Sound, Chatham Strait, and Lynn Canal as the boundary, leaving Baranoff Island to Russia, but giving to the British Juneau, Admiralty Island, and everything to the south and east thereof. This was also rejected. Then Clarence Strait and the Stikine River were proposed, leaving Prince of Wales Island to Russia, but giving to Great Britain the islands of Wrangell and Revilla-Gigedo. This also the Russians rejected. Finally the British commissioners conceded to Russia the whole strip down to 54° 40', but sought as a last resort to have the coast line drawn straight across such arms of the sea as Glacier Bay and Lynn Canal, from headland to headland, so as to give the British access to tidewater. This, too, the Russians, inexorably refused to grant, and in the end they won on this point as on all the others. From first to last the constant and inflexible Russian contention was for Russian possession of an unbroken strip of coast from Mount St. Elias to Portland Canal, and in the treaty of 1825 that contention was explicitly upheld and confirmed.

That Russian title was transferred to the United States in 1867, and from that time to the present the United States has stood for precisely what Russia stood for in 1822–5.

In 1898, however, as already stated, following the discovery, in 1896, of the rich gold deposits in the Klondike district, the Canadian government set up a claim based upon a new understanding of the Anglo-Russian treaty. The main contention, which, by the way, never had any cordial support from qualified experts in Great Britain, was whether the line of demarkation between the southeastern end of Alaska and the British northwest possessions cut through the inlets and estuaries of the Pacific or went around them, leaving all these waterways in American territory and preventing Great Britain from access to the sea. The British contended that the boundary line, which was defined by treaty as running parallel with the sinuosities of the coast at a distance of 30 marine miles inland, except where parallel mountain ranges were nearer, when it was to follow these ranges, was to be construed as running parallel to the coast of the Pacific and not parallel to the shores of the inlets of that sea, thus constituting a political rather than a physical coast line. If the British contention had been granted, Dyea and Skagway, two important ports on the Lynn Canal, and the prominent places of export and import for the Yukon and Klondike gold fields, would be in Canadian territory. So would the Porcupine gold fields.

On account of the apparent clearness of the terms of the Anglo-Russian treaty in 1825 it may seem difficult to imagine how any interpretation different from that argued for by the United States could have been put forth. The original treaty, however, was in French, and dispute arose as to the precise translation of "crête," meaning crest, "lisière," meaning strip, and "côte," usually translated as coast.

The treaty also laid down the boundary on supposed topographical conditions which did not exist. When the treaty was drawn up the framers relied upon some of the maps of Capt. Vancouver, and from observations in the small section of British Columbia which he explored it seemed apparent that the whole coast was bordered by a range of mountains which ran parallel to and at a distance of from 25 to 30 miles from the sea.

As a matter of fact there is a jumble of mountains in various places along the coast, but in no case is there a well-defined watershed. The "crests" mentioned in the treaty were even more difficult to decide upon, and with the difference of opinion as to whether the coast line as intended in the treaty ran through the inlets or around them there were grounds for disputes, for the settlement of which an international tribunal became necessary.

The treaty between the United States and Great Britain, of which the appointment of the Alaska tribunal was the consequence, therefore decided that the following questions should be decided upon:

1. What is intended as the point of commencement of the line?

2. What channel is the Portland channel?

3. What course should the line take from the point of commencement to the entrance to Portland channel?

4. To what point on the 56th parallel is the line to be drawn from the head of the Portland channel, and what course should it follow between these points?

5. In extending the line of demarkation northward from said point on the parallel of the 56th degree of north latitude, following the crest of the mountains situated parallel to the coast until its intersection with the 141st degree of longitude west of Greenwich, subject to the condition that if such line should anywhere exceed the distance of 10 marine leagues from the ocean then the boundary between the British and the Russian Territory should be formed by a line parallel to the sinuosities of the coast and distant therefrom not more than 10 marine leagues, was it the intention and meaning of said convention of 1825 that there should remain in the exclusive possession of Russia a continuous fringe or strip of coast on the mainland, not exceeding 10 marine leagues in width, separating the British possessions from the bays, ports, inlets, havens, and water of the ocean, and extending from the said point on the 56th degree of latitude north to a point where such line of demark-

ation should intersect the 141st degree of longitude west of the meridian of Greenwich?

6. If the foregoing question should be answered in the negative, and in the event of the summit of such mountains proving to be in places more than 10 marine leagues from the coast, should the width of the "lisière" which was to belong to Russia be measured (1) from the mainland coast of the ocean, strictly so-called, along a line perpendicular thereto, or (2) was it the intention and meaning of the said convention that where the mainland coast is indented by deep inlets, forming part of the territorial waters of Russia, the width of the lisière was to be measured (*a*) from the line of the general direction of the mainland coast, or (*b*) from the line separating the waters of the ocean from the territorial waters of Russia, or (*c*) from the heads of the aforesaid inlets?

7. What, if any exist, are the mountains referred to as situated parallel to the coast, which mountains, when within 10 marine leagues from the coast are declared to form the eastern boundary?

The United States made no actual claim. She reiterated her right to territory which she proved had been recognized as hers by Great Britain and by various official acts of Canada. Various maps were produced to show that Russia had been entitled to the disputed territory and that after the purchase of Alaska that same territory was mapped and charted as belonging to the United States.

Among the maps put in evidence was the British Admiralty Chart No. 787, corrected to April 1898, in which the boundary line follows the sinuosities of the actual sea-coast, and deprives Canada of the inlets which cut into the continent. It was proven also that post-offices have been maintained on various points of the disputed strip; that custom-houses have been established there and have collected duties, and that government and mission schools, particularly at the head of the Lynn Canal have been maintained for nearly 20 years. The fact that the possession of the territory by Russians and later by Americans had not been disputed from 1825 until 1898, was also put forth by the United States in support of her claim.

The British contention rested primarily on the claim that it would have been impossible to trace at a distance of 30 miles the intricate convolutions of the line forming the edge of the salt water, and that therefore a general coast line, including many of the islands and disregarding many of the inlets, was the intention of the framers of the Anglo-Russian treaty. If the 30-mile limit were applied to such a coast, the boundary line would of course cut across all the deeper inlets, giving the British immediate access to the interior.

The British also submitted an argument placing a new interpretation of that clause of the treaty which provides that where the boundary line follows the mountain ranges, the crests of these mountain peaks shall mark the precise line of demarkation. It was demonstrated in the rush to the Klondike that there was no general line of mountains anywhere near the coast, but a number of peaks and small mountains were scattered disconnected close along the coast.

The British claim that the boundary line should follow the crests of these isolated peaks, had it been allowed, would have deprived the United States of a great portion of their 30-mile "lisière." The British cited the action of American surveyors in 1893 in support of their interpretation of "coast."

Dr. T. C. Mendenhall, superintendent of the United States Coast and Geodetic Survey, in that year directed his subordinates to carry their operations inland "30 nautical miles from the coast of the mainland in a direction at right angles to its general trend." In regard to the mountains it was contended that a gap does not discontinue the general line of the range.

The official report of the tribunal was signed and issued on 20 Oct. 1903. The signatories were Lord Alverstone, the British commissioner, and the three American commissioners, who constituted a majority of the tribunal, the Canadian commissioners refusing to sign.

All the American claims were granted with the exception of those in regard to questions 2 and 3, in which the British contentions were upheld. The original treaty specified that the line should run from the southernmost point of Prince of Wales Island (Cape Muzon) to Portland Channel. The course of this line, according to the United States, is due east about 70 miles.

The British locate it a little north of east about 66 miles to what they call Portland Channel, and what the Americans call Pearse Channel. The American claim is made on the map of Capt. Vancouver, who first scientifically investigated the territory, and the British claim was made upon the text of Capt. Vancouver's book, which differed slightly from the map.

A substantiation of the American contention would have given to the United States Pearse and Sitklan Islands, which command the entrance to Fort Simpson, to which point Canada proposes to build a new transcontinental railway.

The decision in regard to Portland Channel or Canal gave Canada Pearse and Wales Islands, while the United States obtained Sitklan and Kunnughunnut Islands and the broad southern portion of the channel. Three opinions were also delivered to Messrs. J. W. Foster and Clifford Sifton, the agents respectively of the United States and Canada, one by the United States commissioners discussing the Portland Canal claims; another by Lord Alverstone on the general issue, and a third by the Canadians protesting in the most emphatic language against all the American claims. The chief interest in the decision lay in the conclusions upon the fifth or main question of Lord Alverstone, who by his impartial and high-minded course refuted the assumption on which was based the principal objection to the former treaty, that not even on the bench could a British subject be found who would not persist in upholding the supposed interests of his country, no matter how cogent might be the appeals to his sense of justice or of equity.

The following is an abstract of Lord Alverstone's conclusions:

"The broad, undisputed facts are that the parties were engaged in making an agreement respecting the archipelago and islands off the coast and some strip of land upon the coast itself. The western limit of these islands extends in some places about 100 miles from the coast and the channels or passages between the islands and between the islands and the coast

are narrow waters, their widths varying from a few hundred yards to 13 miles.

"In ordinary parlance no one would call the waters of any of these channels or inlets the ocean. I agree with you as presented on behalf of Great Britain that no one coming from the interior and reaching any of these channels, particularly the head of Lynn Canal or Taku Inlet, would describe himself as being upon the ocean, but on the other hand, it is quite clear that the treaty does regard some of these channels as the ocean. This consideration, however, is not sufficient to solve the question. It still leaves open the interpretation of the word coast, to which the mountains were to be parallel. * * *

"There is, so far as I know, no recognized rule of international law which would by implication give a recognized meaning to the word coast as applied to such sinuosities and such waters different from the coast itself. As I have said more than once, the *locus in quo* to which the treaty was referring precludes the possibility of construing the word coast in any particular article in any special way if it does not refer to the coast line of the continent. I think the words upon the border of the continent comprised within the limits of the Russian possessions in Article V. rather confirm the view that Russia was to get a strip all along the continent, but I do not think that much reliance can be placed upon this because of the provision regarding the rivers and streams in Article VI.

"Turning from the language of the treaty to the record of the negotiations, I have been unable to find any passage supporting the view that Great Britain was directly or indirectly putting forward a claim to the shores or ports at the head of inlets. This is not remarkable inasmuch as no one at that time had any idea that they would become of any importance. * * * The language of both the British and Russian representatives in reporting the conclusion of the treaty to their respective governments is in accordance with the view I have suggested. * * * I have little doubt that if shortly after making the treaty in 1825 Great Britain and Russia had proceeded to draw the boundary provided by the treaty, the difficulties and in certain events the impossibilities of drawing the boundary in strict accordance with the treaty would have been evident.

"I can, therefore, understand and appreciate the contention of Great Britain that under existing circumstances difficulties in delineating the boundaries described must arise in one view and might arise in any view. But these contentions, strong as they are in favor of a just and equitable modification of the treaty, do not, in my opinion, enable one to put a different construction upon the treaty. I think the parties knew and understood what they were bargaining about and expressed the terms of their bargain in terms to which effect can be given. The fact that when, 75 years later, the representatives of the two nations attempted to draw the boundary in accordance with the treaty they were unable to agree as to its meaning does not entitle me to put a different construction upon it.

"In the view I take of the terms of the treaty itself it is unnecessary to discuss the subsequent action. Had the terms of the treaty led me to a different conclusion and entitled me to adopt the view prescribed by Great Britain, I should have felt great difficulty in holding that anything done or omitted to have been done, by or on behalf of Great Britain, prevented her from insisting upon a strict interpretation of the treaty, nor do I think the representations of the map-makers that the boundary was assumed to run around the heads of the inlets could have been properly urged by the United States as sufficient reason for depriving Great Britain of any rights she had under the treaty had they existed."

Alaskan Blackfish, Greenfish, etc. See Blackfish, etc.

Alassio, ä-läs'sē-ō, a small seaport in the province of Genoa, Italy, situated on the Gulf of Genoa, about 48 m. S.W. of the city of Genoa.

Alastor, in Greek mythology, a surname given to Zeus as the avenger; also the name of an avenging demon who follows the sinner and drives him to fresh crime. In the Middle Ages the name was given to a house-demon, the skeleton in the cupboard.

Alatan, a range of mountains in central Asia, forming the boundary between Mongolia and Turkestan.

Alatyr, á-lá-tir', a town in Russia, government Simbirsk, at the confluence of the Alatyr with the Sura, with a considerable trade. Pop. 12,000.

Alau'da, a genus of insessorial birds, which includes the larks. See Lark.

Alaux, al-ō', **Jean,** called "Le Romain," a French painter: b. in Bordeaux 1786; d. 3 March 1864. He was a pupil of Vincent and Guérin; in 1815 took the Prix de Rome with the painting of 'Briseis Finding the Body of Patroclus in the Tent of Achilles.' He executed many portraits and other works. His historical paintings in the Museum of Versailles are famous: 'Battle of Villaviciosa,' 'Valenciennes Taken by Assault by Louis XIV.,' 'States-General of Paris under Philippe de Valois,' 'Assembly of Notables at Rouen under Henry IV.,' 'States-General of Paris under Louis XIII.,' and the 'Reading of the Will of Louis XIV.' He spent nine years in painting the 86 pictures which decorate the hall of the States-General of Paris. He was director of the Academy of France from 1847 to 1850, and in 1851 became a member of the Academy. His brother, Jean Paul Alaux, called "Le Gentil," born in 1788, was director of the School of Design at Bordeaux.

A'lava, a hilly province in the north of Spain, one of the three Basque provinces; area, 1,207 square miles; covered by branches of the Pyrenees, the mountains being clothed with oak, chestnut, and other timber, and the valleys yielding grain, vegetables, and abundance of fruits. There are iron and copper mines, and inexhaustible salt springs. Capital, Vittoria. Pop. about 95,000.

Alb (from Lat. *albus,* white), a clerical vestment worn by priests while officiating in the more solemn functions of divine service. It is a long robe of white linen reaching to the feet, bound round the waist by a cincture, and fitting more closely to the body than the surplice.

Alba, the name of several towns in ancient Italy, the most celebrated of which was Alba Longa, a considerable city of Latium, according to tradition built by Ascanius, the son of Æneas, 300 years before the foundation of Rome. It was at one time the most powerful city of Latium, and the head of a league of the Latin cities, but fell during the reign of Tullus Hostilius, when the town was destroyed and the inhabitants removed to Rome. In later times the site of the ancient Alba Longa became covered with villas of wealthy Romans, whence arose the municipium of Albanum, now Albano (which see). Another Alba, called Alba Fucentia or Fucentis, was near the Lacus Fucinus. The cyclopean walls of the old town are still to be seen in excellent preservation.

Alba, Duke of. See ALVA.

Albacete, a town in Spain, capital of the province of the same name, on the highway between Madrid and Cartagena, on an important line of railway. It lies in a fertile but treeless plain. Albacete, from its position, is a place of considerable business; and carries on trade, both direct and transit, with Murcia, Alicante, Valencia, and Madrid, exporting grain, saffron, and cattle; and importing codfish, sardines, rice, sugar, wine, iron, cloths, etc. A good deal of cutlery is made here.

Alba Longa. See ALBA.

Alban, Saint, protomartyr of Britain, 303. A native of Hertfordshire, he was tortured and executed at Verulamium by command of the prefect, Asclepiodotus. When tranquillity was restored a chapel was erected over his grave; in 795, Offa, king of the Mercians, founded a large monastery upon the spot, and Pope Adrian IV. (1154–9) directed that he should hold the first place among the abbots of England. His festival is celebrated by the Roman Catholic Church on 22 June, and by the Anglican Church on 17 June.

Albani, a powerful family of Rome, which has supplied the Roman Catholic Church with several cardinals. Two of them are well known as patrons of the fine arts: (1) ALBANI, ALESSANDRO, born in 1692; died in 1779; he was a great virtuoso, and possessed a collection of drawings and engravings which at his death was purchased by George III. for 14,000 crowns. (2) ALBANI, GIOVANNI FRANCESCO, nephew of the former, born in 1720; a great friend of the Jesuits, and in every respect liberal and enlightened. His palace was plundered by the French in 1798, when he made his escape to Naples stripped of all his possessions. Died in 1803.

Albani, Francesco, a famous painter: b. Bologna 1578; d. 1660. He entered the school of Dionysius Calvaert, a Flemish painter, who had a great reputation in Bologna. Albani was one of his most distinguished scholars, but quitted him for Ludovico Carracci, under whose instruction he made rapid progress. He labored here several years in connection with Domenichino, to whom he was closely attached by friendship and love of art; and some resemblance is perceptible in their manner of coloring. But in invention he surpasses his friend, and indeed all his rivals of the school of Calvaert. His female forms Mengs places above those of all other painters. Among the best known of his compositions are the ‹Sleeping Venus,› ‹Diana in the Bath,› ‹Danaë Reclining,› ‹Galatea on the Sea,› ‹Europa on the Bull.› Scriptural subjects he has less frequently selected, but when he has, the paintings are principally distinguished for the beauty of the heads of the angels. He had a numerous school in Rome and Bologna. The scholars of Guido, with whom he vied, accused him of effeminacy and weakness of style, and maintained that he knew not how to give any dignity to male figures. He has been called the Anacreon of painters.

Albani, Marie Emma (Lajeunesse), a dramatic soprano and opera singer: b. 1 Nov. 1852, in Chambly, near Montreal, Canada. After studying with Lamperti, at Milan, she made her début at Messina (1870), in 'La Sonnambula,' under the name of Albani, in compliment to the city of Albany, where her public career began. In 1878 she married Ernest Gye of the Covent Garden Theatre.

Albania, an extensive region in west European Turkey between the Adriatic Sea, Greece, Macedonia, and Montenegro. Upper or northern Albania formed a part of the Illyria of the Romans; lower or southern Albania corresponds to ancient Epirus. It comprises the vilayets of Scutari and Janina and parts of Monastir and Kossovo. It forms the southwestern portion of the remaining immediate possessions of European Turkey, and extends along the western shore of the Balkan peninsula, from the river Bojana to the Gulf of Arta. To the north it is bounded, since 1878–80, by the newly won Montenegrin territory and by Bosnia; on the south it is separated, since 1881, from Greece by the river Arta. The eastern boundary is a mountain range, which to the north attains an altitude of 7,990 feet. Westward of this range lie parallel chains enclosing long, elevated valleys sinking to level strips along the coast, which mostly consist of unhealthy swamps and lagoons. The highlands advance to the sea, forming steep, rocky coasts. One promontory, the Acroceraunian, projecting in Cape Linguetta far into the sea, reaches a height of 6,642 feet. There are three lakes, Scutari, Ochrida, and Janina. The principal rivers are the Boyana, Drin, Shkumbi, and Artino. A fine climate and a favorable soil would seem to invite the inhabitants to agriculture, but in the north little is cultivated but maize, with some rice and barley in the valleys; the mountain terraces are used as pastures for numerous herds of cattle and sheep. In the south the slopes of the lower valleys are covered with olives, fruit, and mulberry trees, intermixed with patches of vines and maize, while the densely wooded mountain ridges furnish valuable supplies of timber. The plateau of Janina yields abundance of grain; and in the valleys opening to the south the finer fruits are produced, along with maize, rice, and wheat. The inhabitants form a peculiar people, the Albanians, called by the Turks Arnauts, and by themselves Skipetar.

They are half-civilized mountaineers, frank to a friend, vindictive to an enemy. They are constantly under arms, and are more devoted to robbery than to cattle-rearing and agriculture. They live in perpetual anarchy, every village being at war with its neighbor. Many of them serve as mercenaries in other countries, and

they form the best soldiers of the Turkish army. At one time the Albanians were all Christians; but after the death of their last chief, the hero Skanderbeg, in 1467, and their subjugation by the Turks, a large part became Mohammedans. Their language is one of the eight chief Indo-Germanic g oups, and represents the ancient Illyrian; it is found not only in Albania, but in southern Italy and Sicily. The former notion that its affinities were prevailingly Greek was derived from the number of Greek loan-words in its southern branch, the Toskish, the northern and more primitive being called Gegish: the affiliation of the whole is rather to Slavic than any other. While retaining its grammatical structure, its vocabulary has been largely transformed by borrowing from neighbors; Latin most, then Greek, Slavic, and Turkish. It has almost no literature except folk songs and tales. The Gegish uses the Roman alphabet, the Toskish the Greek, with some changes.

Albans, St. See St. Albans.

Albany, Louisa Maria Caroline, or **Aloysia,** Countess of, a princess of the Stolberg-Gedern family: b. 1753; d. 29 Jan. 1824. She married in 1772, the English pretender, Charles Edward Stuart, after which event she bore the above title. Her marriage was unfruitful and unhappy. To escape from the barbarity of her husband, she retired, in 1780, to a cloister, and afterward to the house of her brother-in-law at Rome, where she met the poet Alfieri, to whom, soon after the death of her husband, she was privately married. Alfieri attributed to her his poetic inspiration. (See Alfieri.) She died at Florence, her usual place of residence, in her 72d year. Her ashes and those of Alfieri now repose under a common monument in the church of Santa Croce at Florence.

Albany, Ga., county-seat of Dougherty County, on the Albany & North Seaboard Air Line, Central Ga., and Plant System R.R.'s, at the head of navigation on the Flint River, about 175 m. W. from Savannah. The city has large manufacturing interests, and is the centre of one of the most productive agricultural regions in the State. It is governed by a mayor and a council. Pop. (1900) 4,606.

Albany, Mo., city and county-seat of Gentry County, on the Chicago, B. & Q. R.R., about 82 m. N.E. from Kansas City. The Central Christian College and the Northwest Missouri College are situated there. The city, first settled in 1845, has a mayor and council. Pop. (1900) 2,025.

Albany, N. Y., State capital and seat of Albany County, on the right (west) bank of the Hudson, 143 miles north of New York, 200 miles west of Boston, 297 miles east of Buffalo. Besides its political importance as the capital, its commercial and manufacturing status is high. Of old for many years the starting point of all the enormous eastern travel and traffic to the Great West, over the Erie Canal (q.v.), connecting it with the Great Lakes at Lake Erie; it is still an important port and the intersecting point of the great western as well as northern rail and water routes. With New York and the ocean it is connected by the imperial Hudson, of which it is the head of navigation for large steamers (smaller ones going on to Troy, six miles above). The Erie Canal is still a great commercial advantage, and will soon be more so; while the Champlain Canal gives access not only to western Vermont, but to the St. Lawrence and the heart of Canada, with the foreign business centring at Montreal. By rail it joins the western and northern traffic of the New York Central Railroad system (the Adirondack region, Vermont, and Canada) and that of the Delaware & Hudson Railroad with the western traffic of central New England over the Boston & Albany branch of the New York Central road, the Fitchburgh branch of the Boston & Maine Railroad and the Rutland Railroad.

Trade and Manufacturing.— The through freight lines now leave little transhipment to be done at Albany, though it still remains an important passenger centre; but commerce and industries are conservative, and it retains much of both given it by its position in earlier times, as a distributing point and terminal. In particular, the great Canadian and Adirondack forests to the north have made it an immense lumber port. Its manufactures are of wide and well-known importance, the greatest being iron goods,— foundries and stove works,— wood and brass; combined wood and metal, as carriages and wagons; brick; shirts, collars, and cuffs; clothing and knit goods; shoes; flour; tobacco and cigars; and brewery products; billiard balls; dominoes; checkers and embossed blocks.

In 1900 the city contained 1,566 manufacturing establishments with $21,328,764 capital, employing 14,092 persons, paying $7,127,864 in wages and $11,121,501 for materials, and having a total output of $24,992,021.

Finances.— The assessed valuation of taxable property in 1903 was $68,672,887 and the net public debt in 1903 was $1,318,435. The annual and municipal outlay is about $2,600,000, of which $300,000 is for schools, $157,000 for police and $150,000 for the fire department. There are six national banks, with aggregate capital of $1,750,000, two trust companies with a capital, surplus and profits of $1,135,000, and seven savings banks with a surplus (at market value) of $4,621,941, and amount of deposits of $55,496,220.

Interior.— The city has a river frontage of four miles, and extends west five miles from a narrow alluvial strip often flooded in the spring, over a steep rise to a sandy table-land 150 to 200 feet above tide-water, divided into four elevations and their corresponding valleys. It has 85 miles of streets, paved with granite, asphalt, and brick; gas and electric light plants; and over 30 miles of electric street railways within its limits, several suburban lines running to towns at a distance, centring in Albany: these lines reach Troy, Cohoes, Saratoga, Glens Falls, Lake George and Warrensburgh in the north, a distance of 71 miles. Sand Lake in the northeast, a distance of 15 miles; Schenectady, Amsterdam, Johnstown, and Gloversville in the west, a distance of 50 miles, and Hudson in the south, a distance of 38 miles. The river is crossed by two railroad and foot bridges and one wagon bridge to Rensselaer (formerly Greenbush). The water supply is partly taken by gravity from an artificial lake five miles west, and partly pumped from the river, with a public filtration system. This plant covers 20 acres of ground, has eight filter beds and filters 15,000,000 gallons of water daily. The parks, 11 in num-

THE STATE CAPITOL AT ALBANY.

ber, contain 305 acres; the largest is Washington Park of 90 acres with a lake 1,700 feet long. This park contains the celebrated 'Burns' statue by Charles Calverly and the bronze and rock fountain 'Moses Smiting the Rock' by J. Massey Rhind. The three cemeteries cover 440 acres. President Arthur's tomb is in the handsome Rural cemetery of 280 acres, situated four miles north of the city.

Buildings.— The great show building of Albany is the magnificent capitol, begun in 1871 and continued by several different architects at a total outlay to date of some $25,000,000. The lack of unity in plan makes itself perceptible both in looks and cost, millions have been spent in alterations and reconstructions, and some of the mechanical work and material have been poor; but though more might have been obtained for the money, the capitol is a noble structure. It is of Maine granite, in the Renaissance style; is 300 x 400 feet and covers more than three acres; it occupies a most sightly position on the hillside facing the river, and including part of the site of the old capitol built in 1806. Besides its rooms for the legislative bodies and officials and the court of appeals, it contains the magnificent State library of over 450,000 volumes, and many interesting relics of the Revolution and Civil War. The grand western staircase in the western end of the building is said to be the finest staircase in the world: it cost nearly two millions of dollars.

The State Hall and the City Hall face it; the former of white marble, and the latter of red sandstone with grand campaniles and Romanesque doorways. The custom-house and post-office are in the government building at the foot of State Street. Among other buildings are the State Arsenal, Harmanus Bleecker Hall, the old Schuyler mansion, now used as an orphan asylum, and the Agricultural and Geological hall. In 1893 the second Van Rensselaer manor-house, built 1765, was removed to the Williams College campus, of Williamstown, Mass.

The buildings of religious and educational institutions are also creditable features: Albany is the seat of both Roman Catholic and Protestant Episcopal bishoprics, and has over 70 churches. Very notable are the cathedrals of the Immaculate Conception (R. C.) and All Saints (P. E.). St. Peter's Church (P. E.) is reputed one of the finest specimens of the French Gothic type of architecture in the United States.

The Madison Avenue and First Reformed churches were organized in 1642, incorporated in 1720 and continued as one church until 1799, when separate edifices were built; these two churches continued under one government until 1815.

The public school property is valued at nearly $1,000,000. Other institutions of learning are the law and medical departments of the Union University at Schenectady (originally independent academies of 1851 and 1839), Albany Academy, the State Normal College, St. Agnes School, the Albany Female Academy, and the Convent of the Sacred Heart. Also the Dudley Observatory and the Bender Hygienic Laboratory. Albany has a fine city hospital built in 1899 on the pavilion plan and covering 16 acres with 150,000 feet of floor space; the Albany penitentiary, dating from 1848 — from three to four hundred prisoners a year are confined in this institution.

Government.— Biennial mayor; city council, the president elected at large, the aldermen by wards; and boards of finance, public works, public safety, assessment and taxation, charities and correction, judiciary, and law. For their composition, see statutes of New York State, cities of the second class. The mayor also appoints a sealer of weights and measures, and supervisors are elected.

Population.— In 1800, 5,289; 1820, 12,630; 1840, 33,721; 1860, 62,367; 1880, 90,758; 1890, 94,923; 1900, 94,151 (17,700 foreign).

History.— Albany, as an old frontier town and strategic post against the French settlements in the 18th century wars, is of much historic interest. Next to Jamestown, Va., and St. Augustine, Fla., it was the oldest settlement in the Union; if the 13 colonies only are included, and Jamestown thrown out as deserted since 1676, it may perhaps be called the oldest with a continuous life, though its actual settlement as a residence is later than Plymouth. (For early discovery, see AMERICA; HUDSON; VERASSANO.) About 1540 a French trading-post was set up there for a time. In 1614 the Dutch, following Hudson's lead, established a factory, on Castle Island, called Fort Nassau, in 1617 removed to the mainland and called Beverwyck. The first settlers were 18 Walloon families (Huguenot refugees from Belgium — Peter Minuit, the first director-general of New Amsterdam, was a Walloon), and Fort Orange (Latinized Aurania) was built the same year, near the present capitol. In 1626 a war with the Mohawks forced the temporary abandonment of the village. In 1629 Killian Van Rensselaer, having obtained from the Dutch government a large land-grant near by, colonized it with Dutch settlers and rented the land to them as patroon. (See ANTI-RENT WAR; PATROON.) This, as always, ended in a chronic dispute over the extent of his legal rights and jurisdiction, which was not settled till after the ownership of the Dutch settlements was transferred by the English conquest to the Duke of York and Albany (later James II.) after whom Fort Orange was renamed. In 1686 it received a city charter (its bi-centennial was celebrated in 1886) from Gov. Thomas Dongan; its first mayor (appointed by the governor, though the council was elected) was Peter Schuyler. The English settlers rapidly increased, but Albany was long a Dutch city. In the French and Indian wars it was a stockaded rendezvous, arsenal, and hospital, the refuge of the border. In 1754 it was the meeting-place of the first Provincial Congress, which formed "a plan of a proposed union of the several colonies" (see ALBANY CONGRESS). In 1777 it was Burgoyne's objective point, where he was to meet the expeditions up the river and from Canada. After being for many years later the occasional seat of State government, it became the permanent capital in 1797, the centennial of which it celebrated 6 Jan. 1897. Its rapid growth began with the opening of the Erie Canal in 1825, making it the terminal for western business. Within 35 years it had increased fivefold. In 1848 it was partially destroyed by fire.

WILLIAM BOUCHER JONES,
Secretary Albany Chamber of Commerce.

Albany, Ore., city and county-seat of Linn County, on the Southern Pacific and the Cowalli & E. R.R.'s, and the Willamette River, about 25 m. S. by W. from Salem. The city has good water-power from the Willamette River, and has large manufacturing interests. It ships both grain and flour. Pop. (1900) 3,149.

Albany, West Australia, in Plantagenet co., on King George's Sound. It has one of the finest harbors in Australia, and is a port of call for the steamers of the Peninsular & Oriental Co. It is a consular station of the United States. Pop. about 3,000.

Albany Congress, an assembly of representatives of the seven northern British-American colonies (Massachusetts, New Hampshire, Connecticut, Rhode Island, New York, Pennsylvania, and Maryland), called together in 1754 by the British government to consult in regard to the threatening French war. It met 19 June, and two plans were proposed: (1) a league with the Five Nations, which was carried out; (2) a proposal offered by Franklin for a political union. In this a common president was proposed, and a great council representing the different colonies. The president was to be appointed by the Crown; to be also commander-in-chief, to commission all civil officers and appoint all military ones, and have a veto on the council. The council was to consist of three-year members, two to seven from each colony; not to be adjourned or dissolved or kept over six weeks in session against its will; it could lay taxes, maintain troops, build forts, nominate civil officers, manage Indian affairs, and authorize new settlements; and its acts were to be valid unless vetoed within three years by the Crown. This plan was rejected by the British Crown because it gave too much power to the colonies and by the colonies because it gave too much power to the Crown. The significance of this congress lies in the fact that it stimulated the union of the colonies which was afterward accomplished.

Albany Regency, in American political history, the nickname of a powerful group of Democratic leaders in New York State, who controlled the party machinery there and acted together for influence in State and national affairs about 1820–54: so named because its members either lived near the capital or held offices which made it their headquarters. Its origin and essence as an aristocracy of «bosses» lay in the system of frequent elections among a democracy, which puts nominations into the hands of professionals who will be paid in some shape, creating a permanent standing army of political managers. The Regency was the unofficial staff of this army, and was larger than in other States from the imperial field which New York offered for great careers; but it could not have perpetuated its power but for the means of rewarding friends and punishing enemies given it by the «spoils system» (a name derived from the saying of one of its members, William L. Marcy, in 1833, that «to the victors belong the spoils»). While personally upright, and strong opponents of corruption, they held firmly to this, the very spring of corruption: the giving or taking away of offices, the use of public contracts for printing or other work or supplies, etc. That this was its cement is shown by the fact that after the bitter factional split of 1848 (see BARNBURNERS) had given the other party this patronage to use against it, the Regency was reduced in a few years to unorganized individuals. The members of course kept themselves in high or profitable positions according to their capacities or preferences; several alternating between State and national preferment, but never neglecting the former basis even in the latter service. The earliest and greatest leader was Martin Van Buren, State attorney-general, United States senator 1821–8, resigning to become governor of New York, Jackson's secretary of state, Vice-President, President. Others were William L. Marcy, State comptroller, judge of the New York supreme court, United States senator 1831, resigning 1833 to become governor of New York, Polk's secretary of war, Pierce's secretary of state; Silas Wright, Congressman, State comptroller, United States senator 1833 (succeeding Marcy), resigning 1844 to become governor of New York; John A. Dix, State secretary of state, United States senator 1845–9, Buchanan's secretary of the treasury, again governor of New York 1872–4; Benjamin F. Butler, Van Buren's attorney-general and acting secretary of war; while others held only State offices,— Azariah C. Flagg, State secretary of state and afterward twice comptroller; Edwin Croswell, State printer, editor of the Albany *Argus,* leading Democratic organ; Benjamin Knower, State treasurer; and others held no offices,— Dean Richmond, Roger Skinner, Peter Cagger, Samuel A. Talcott, etc. (Hammond's 'Political History of New York' is a shrewd analysis of State politics from a judicious and experienced observer.) Afterward Samuel J. Tilden, Daniel Manning, and others of high stamp, by sagacity of central management, preserved in a manner the traditions of the older group, though they never had its patronage to use for discipline.

Albatross (corrupted from Portug. *alcatroz,* the cormorant; from Ar. *al,* the; *qadus,* bucket, on account of its pouch), a large, almost exclusively pelagic bird of the family *Diomedeidæ,* a feature of the lonely southern oceans. They are rarely seen on the north Atlantic, but frequent nearly all other seas, and are never seen ashore except on the barren antarctic islands where they breed. They have great powers of flight and follow ships for long distances to pick up offal. Their appetites are rapacious, their natural diet consisting of any fishes, mollusks, or other animal matter which they find at the surface of the water; they do not dive. Sailors are fond of them and have a strong superstition against killing them. Like their allies, the petrels, the albatrosses have three fully-webbed toes, while the hind toe is either entirely wanting or represented by a claw. The bill of an albatross is four inches or more long, very thick, and finished by a powerful hook at the tip. The nostrils open from round horizontal tubes placed one on each side of the bill, but at its base, instead of together on top as with the petrel. The wings are extremely long and pointed, the tail short and somewhat rounded. The feathers of the body form so thick a coat as to withstand both water and

severe, long-continued cold; owing to the extreme length of the wing the number of flight feathers on it is greater than on the wing of any other bird. The single large white egg of the albatross is usually hatched on the bare earth. Two rather small species of albatross, the short-tailed (*Diomedea albatrus*) and the black-footed (*Diomedea nigripes*), occur on the western coasts of North America; these are about three feet long and seven feet across the wings. The sooty albatross (*Phœbetria fuliginosa*), of much the same size, belongs broadly to the Pacific Ocean. There are from seven to nine other species, of which the largest is the wandering albatross (*Diomedea exulans*) of the southern oceans. It is 4 or 5 feet long and 10 to 12 feet from tip to tip of wings. Its color is white, with black bars across the wing coverts and across part of the back. This is probably the best known species in the family.

Albaugh, John, American actor: b. Baltimore, 30 Sept. 1837. Under the management of Joseph Jefferson he made his first appearance in a play called ‘Brutus,’ in 1855. For 13 years he played throughout the United States and in 1868 became manager of various theatres, latterly in Washington and Baltimore. He retired from the stage in 1899 and devoted his leisure to stock-raising.

Albay, a province in the southeast of Luzon, Philippine Islands, and the richest hemp-growing district on the island. It has yielded as much as 40,000 tons of hemp in a season. The province contains a picturesque volcano, Mayon, which has had several destructive eruptions, the last in 1888. In January 1900 Brig.-Gen. William A. Kobbe, United States Volunteers, was appointed military governor of the province and Catanduanes Island, with temporary authority over Samar and Leyte Islands for the purpose of controlling the hemp-growing country and occupying and opening to trade the various hemp ports. The principal towns in the province are Albay (the capital), Tivi, Malinao, Tobaco, Malilipot, Bagacay, Libog, Legaspi, Manito, Libon, Polangui, Ligao, Oas, Guinobatan, Cagsaua, and Camalig. Vicol is almost the exclusive language of the province. The industries are hemp-growing (annual value $4,750,-217), ship-building, gold, silver, coal, and iron mining. Pop. (1900) 195,129.

Albemarle, The, a Confederate ram, which for a long time did great damage among Union shipping, but was finally destroyed by W. B. Cushing (q.v.), who was entrusted at different times with various difficult feats of the sort. Cushing, while the Albemarle was at moorings in the harbor of Plymouth, N. C., on the night of 27 Oct. 1864 entered the harbor and succeeded in blowing up the vessel by means of a torpedo. The Albemarle was rendered completely useless, and Cushing obtained lieutenant-commander's rank and the thanks of Congress for his execution of the exploit.

Albemarle Sound, a shallow and narrow body of water on the coast of North Carolina, separated from the Atlantic Ocean by low sand islands. The greatest depth is about 18 feet, but it is generally so shallow as to be unnavigable except where it has been dredged. The water is generally fresh and is not affected by the tides. It extends directly west from the ocean about 60 miles. It is the outlet of many of the streams of northeastern North Carolina, chief of which are the Roanoke and Chowan.

Alberoni, Giulio, cardinal and minister of the king of Spain: b. Firenzuola, Parma, 1664; d. Rome 1752. He soon gained the favor of powerful patrons, especially the Duke of Vendôme, whom he accompanied to Paris and then to Spain, the Duke being appointed generalissimo of the armies of Philip V. Having made himself a favorite of the Spanish king, he rose to be prime minister, became a cardinal, was all-powerful in Spain after the year 1715, and endeavored to restore it to its ancient splendor. He reformed abuses, created a naval force, organized the Spanish army on the model of the French, and rendered the kingdom of Spain more powerful than it had been since the time of Philip II.

Albert, Prince (ALBERT-FRANCIS-AUGUSTUS-CHARLES-EMMANUEL), Prince of Saxe-Coburg-Gotha, and Prince Consort of England, second son of Ernest I., Duke of Saxe-Coburg, was born at the Rosenau, a castle near Coburg, on 26 Aug. 1819. In 1837 he entered the University of Bonn, where he devoted himself to the studies of political and natural science, history, philosophy, etc., as well as to those of music and painting. On leaving the university he made a tour through the chief cities of Italy with Baron Stockmar. On 10 Feb. 1840 he married his cousin, Queen Victoria of England. An allowance of £30,000 a year was settled upon the prince, who was naturalized by act of Parliament, received the title of Royal Highness by patent, was made a field-marshal, a Knight of the Garter, of the Bath, etc. Other honors were subsequently bestowed upon him, the chief of which was the title of Prince Consort (1857). He always took a deep and active interest in the welfare of the people in general. His services to the cause of science and art were very important; he presided over the commission appointed in 1841 to consider the best means of rebuilding the houses of parliament and the great exhibition of 1851 owed much of its success to his activity, knowledge, and judgment. He died of typhoid fever on 14 Dec. 1861, after a short illness. A collection of his speeches and addresses was published in 1862. A biography of the prince by Sir Theodore Martin has been published in five volumes, London 1875–80.

Albert I., Duke of Prussia, son of Frederick, Margrave of Ansbach and Baireuth, and grandson of Albert Achilles, Elector of Brandenburg: b. 17 May 1490; d. 20 March 1568. In 1511 he was chosen by the Teutonic Knights grand master of their order. Being the son of Sophia, the sister of Sigismund, king of Poland, and descended from one of the most powerful German families, the Knights hoped by his means to be freed from the feudal superiority of Poland and placed under the protection of the empire. Being recognized by Poland he proceeded to Königsberg and assumed the government in 1512. He refused the oath of allegiance to Poland, which the previous grand master had evaded, and prepared for resistance. In 1520, after protracted negotiations, Sigismund attempted to enforce submission by an invasion of the territories of the Order, but the contest was without decisive result, and in

the following year a truce of four years was agreed to at Thorn. The latter years of his reign were troubled with many intrigues, foreign and domestic; in 1532 he was put under the ban of the empire, but succeeded in transmitting his succession to his son.

Albert I., Margrave of Brandenburg, surnamed the Bear, from his heraldic emblem, was the son of Otto the Rich, Count of Ballenstädt. As Marquis of Lusatia he served the Emperor Lothaire with credit in his war with Bohemia. The Diet afterward withdrew Lusatia from him, but the emperor for further services conferred on him in 1134 the margravate of Brandenburg. In 1136–7 he made incursions into the territory of the Wends, who disturbed his government, and checked their disorders. In 1138 the Emperor Conrad conferred on him the duchy of Saxony, of which he had deprived Henry the Proud. This led to a war with Henry, in which Albert was deprived of Brandenburg, but was restored by an armistice negotiated by the ecclesiastical electors. On the death of Henry (1139) he reassumed the title of Duke of Saxony. A combination was then formed against him, which, in spite of the favor of the emperor, reduced him to extremities. Peace was concluded in 1142. Albert resigned Saxony, and Brandenburg was raised to an immediate fief of the empire. He acquired at the same time by inheritance from Przibislas, a Vandal king who had taken his name in baptism, the country between the Elbe and the Oder. He made his new possessions a fief of the empire, and in order the better to guard them removed his residence to Brandenburg. In 1148 he led an expedition into Pomerania, and in the following year induced the duke of that country to embrace Christianity. In 1150 he was raised to the electoral dignity. In 1157 he made a third expedition against the Wends, conquered their country, and colonized it with agriculturists from Germany, Holland, and Zealand. In 1164 he went on a crusade to the Holy Land. Another war broke out between him and Henry, Duke of Saxony, which was terminated to the advantage of the latter in 1168 by the mediation of the Emperor Frederick I. In 1169 Albert remitted his estates to his son. He died in 1170. The origin of Berlin, Kölln, Aken on the Elbe, and other towns, is attributed to the colonies founded by him.

Albert I., Duke of Austria, and afterward emperor of Germany: b. 1248; son of Rudolph of Hapsburg, who had a short time before his death attempted to place the crown on the head of his son. But the electors, tired of his power, and emboldened by his age and infirmities, refused his request and indefinitely postponed the election of a King of the Romans (the title of the designated successor of the emperor). After the death of Rudolph, Albert, who inherited only the military qualities of his father, saw his hereditary possessions, Austria and Styria, rise up in rebellion against him. He quelled by force this revolt, which his avarice and severity had excited: but success increased his presumption. He wished to succeed Rudolph in all his dignities, and without waiting for the decision of the Diet seized the insignia of the empire. This act of violence induced the electors to choose Adolphus of Nassau emperor. The disturbances which had broken out against him in Switzerland, and a disease which deprived him of an eye, made him more humble. He delivered up the insignia and took the oath of allegiance to the new emperor. Adolphus, after a reign of six years, having lost the regard of all the princes of the empire, Albert was elected to succeed him. A battle ensued near Gellheim, in which Adolphus fell by the hand of his adversary. The last barrier had fallen between Albert and the supreme power, but he was conscious of having now an opportunity of displaying his magnanimity. He voluntarily resigned the crown conferred on him by the last election, and as he had anticipated was reelected. His coronation took place at Aix-la-Chapelle in August 1298, and he held his first diet at Nuremberg with the utmost splendor.

But a new storm was gathering over him. The Pope, Boniface VIII., denied the right of the electors to deprive Adolphus of the imperial dignity and bestow it upon one who had caused the death of the legitimate sovereign. He accordingly summoned Albert before him to ask pardon and submit to such penance as he should dictate; he forbade the princes to acknowledge him, and released them from their oath of allegiance. The archbishop of Mainz from a friend became the enemy of Albert and joined the party of the Pope. On the other hand, Albert formed an alliance with Philip le Bel of France, secured the neutrality of Saxony and Brandenburg, and by a sudden irruption into the electorate of Mainz forced the archbishop not only to renounce his alliance with the Pope but to form one with him for the five ensuing years. In April 1301 Boniface forbade all submission to Albert until he would go to Rome and repair his crimes. The next year Albert entered into negotiations with the Pope, in which he again showed the duplicity of his character. He broke his alliance with Philip, acknowledged that the Western Empire was a grant from the Popes to the emperors, that the electors derived their right of choosing from the see of Rome, and promised to defend with arms the rights of the Pope, whenever he should demand it, against any one. As a reward Boniface excommunicated Philip, proclaimed him to have forfeited his crown, and gave the kingdom of France to Albert. Philip in revenge annoyed and persecuted the Pope.

Albert was engaged in unsuccessful wars with Holland, Zealand, Friesland, Hungary, Bohemia, and Thuringia. While preparing to revenge a defeat which he had suffered in Thuringia he received the news of the revolt of the Swiss, and saw himself obliged to direct his forces thither. The revolt of Unterwalden, Schwyz, and Uri had broken out 1 Jan. 1308. Albert had not only foreseen this consequence of his oppression but desired it, in order to have a pretence for subjugating Switzerland entirely to himself. A new act of injustice, however, put an end to his ambition and life. Suabia was the inheritance of John, the son of his younger brother Rudolph. John had repeatedly asserted his right to it, but in vain. When Albert set out for Switzerland John renewed his demand, which was contemptuously rejected by Albert. John, in revenge, conspired with his governor, Walter of Eschenbach, and three friends against the life of Albert. The con-

spirators took advantage of the moment when the emperor, on his way to Rheinfelden, was separated from his train by the river Reuss, and assassinated him. Albert breathed his last, 1 May 1308, in the arms of a poor woman who was sitting on the road.

Albert Lea, Minn., county-seat of Freeborn County, on the Chicago, M. & St. P., the Burlington, C. R. & N., and the Minneapolis & St. L. R.R.'s, about 100 m. S. of St. Paul and 10 m. N. of the boundary of Iowa. The presence of many lakes and artesian wells of chalybeate waters make the city and neighborhood a popular summer resort. It is the market town for a large agricultural and dairy region and has considerable manufacturing interests. It is the seat of a Presbyterian college for women (est. 1855), and a Lutheran Academy. Pop. (1900) 4,500.

Alberta, a Canadian Northwest Territory, created in 1882, and named for H. R. H. Princess Louise, wife of the Marquis of Lorne, then Governor-General. Area, 101,521 sq. m.; chief towns, Calgary, Edmonton, Lethbridge, and Strathcona (q.v.). The southern part is open and rolling, with timber along the streams and in the foot-hills; the northern is more or less timbered throughout. The drainage is about equally northward and eastward through the Athabascan and Saskatchewan river systems; some small streams in the south are of the Missouri system. The winters are mild, with little snow, and the summers hot and dry. The rainfall is small, but the melting snow in the mountains affords an abundance of water for irrigation. The winter storms are severe, but the warm west wind, the Chinook, disperses the snow rapidly, and cattle and horses graze all winter. The soil is good in the northern and eastern parts. Ranching and dairying are the chief industries; extensive irrigation has increased general farming in recent years. The natural resources are coal, petroleum, natural gas, building stone, and gold. The mountain district about Banff has been set apart by the Dominion Government as a national park. Three branches of the Canadian Pacific Railway (q.v.) traverse the territory, and a short independent line connects Lethbridge with the Great Northern Railway at Great Falls, Montana. The projected lines of the Canadian Northern and Grand Trunk Pacific Railways (q.v.) will pass through Edmonton and the northern part. Pop. (1904) about 70,000. On 1 Sept. 1905 the western portion of Athabasca was added to Alberta, thus nearly doubling its area and materially increasing its population.

Alber'tus Magnus, or Albert the Great, Count of Bollstädt, a distinguished German scholar of the 13th century: b. 1200; d. 1280. He studied at Padua, became a monk of the Dominican order, teaching in the schools of Hildesheim, Ratisbon, and Cologne, where Thomas Aquinas became his pupil. In 1245 he went to Paris and publicly expounded the doctrines of Aristotle. It was through his teaching that the philosophy of the Stagyrite became predominant in the Middle Ages. He became a rector in the school of Cologne in 1249; in 1254 he was made provincial of his order in Germany; and in 1260 he received from Pope Alexander IV. the appointment of Bishop of Ratisbon. In 1263 he retired to his convent at Cologne, where he composed many works, especially commentaries on Aristotle.

Albicore, or Albacore. See TUNNY.

Albigenses, a religious sect, coming first into prominence in the 12th century, and taking its name from Albi, their principal stronghold. What their doctrines were has not been determined, as no formal statement of them was ever drawn up. It appears that the Albigenses held beliefs similar to those of the Patarins in Italy, the Bulgarians in France, and other similar sects. They styled themselves Cathari the Pure and traced their doctrines to the Manichean sect known as Paulicians, that settled in Bulgaria, whence their tenets spread to France.

They taught the doctrine of the Manicheans, that there are two opposing creative principles, one good, the other evil; the invisible word proceeding from the former, the body and all material things from the latter. «Their teachers assumed a great simplicity of manners, dress, and mode of life. They inveighed against the vices and worldliness of the clergy, and there was sufficient truth in their censures to dispose their hearers to believe what they advanced and reject what they decried. They also rejected the Old Testament, said that infant baptism was useless, and denied marriage to the 'perfect' as they called their more austere members.» (Addis and Arnold's 'Catholic Dictionary'.)

On the other hand the license permitted to the imperfect gave rise to so much fanaticism and grave social and moral disorders as to threaten the destruction of Christian civilization in the heart of France. They had increased very much toward the close of the 12th century in the south of France, about Toulouse and Albi, and in Raymond, Count of Toulouse, they found a patron and protector. Innocent III., after trying in vain to reform the abuses prevalent among them, was so incensed by the assassination of the papal legate, Peter of Castelnau, in 1208, that he proclaimed a crusade against them, and was supported by the king of France.

An army was accordingly collected, large numbers of those composing it being mere mercenaries and adventurers brought together by the hope of plunder rather than by zeal for the Catholic faith. The chief leader was Simon de Montfort, father of the well-known Earl of Leicester. Raymond's territories were ravaged, and in 1209 the crusaders took Beziers by storm, and put a number of the inhabitants to the sword. Simon de Montfort was equally severe toward other places in the territory of Raymond and his allies, of whom Roger, nephew of Raymond, died in a prison and Peter I., king of Aragon, in battle. The lands taken were presented, as a reward for his services, to Simon de Montfort, who, however, was killed at the siege of Toulouse in 1218. When Innocent III. heard of the cruelties of the invading armies he recalled his legate Milo for his weakness in not restraining Simon and restored to Raymond the captured territory. Soon after, however, Raymond once more espoused the cause of the Albigenses. He died in 1222, under excommunication, and his son, Raymond VII., was obliged to defend his inheritance against the legates and Louis VIII. of France, who fell in 1226 in a campaign against the Albigenses. After thousands had fallen on

both sides a peace was made in 1229 by the terms of which Raymond was released from the penalties in consideration of a large tribute. He ceded Narbonne, with several estates, to Louis IX., and made his son-in-law, a brother of Louis, heir of his other lands.

Albinism, a condition in which there is a congenital absence of pigment in the hair, eye, and skin. Animals so affected are albinos. Albinism is also present in the flowers of many if not all plants, white flowers occurring among those of other color on the same plant. Albinos have been known among all races and all peoples, hence neither climate nor race are its causative factors. Rare in many races, it occurs frequently in others, as for instance in the Zuni and other tribes of Arizona. The most widely accepted theory is that the condition is due to an arrest of development of the pigment layers in the embryo. Affections of the eye are the most important disagreeable features for albinos.

Albion, the earliest name by which the island of Great Britain was known, employed by Aristotle, and in poetry still used for Great Britain. The Greeks and Romans probably received the name from the Gauls, in whose language it would mean mountain-land or white-land, from the Celtic *alp, alb*, said to mean high or white (whence also Alps), the latter name being given to it in reference to the chalky cliffs on the coasts.

Albion, Mich., city in Calhoun County, situated on Kalamazoo River, the Lake Shore & M. S. and the Michigan C. R.R.'s, 28 miles south of Lansing. It has three banks, with a combined capital of $185,000; six churches and good schools. Albion College (q.v.) is located here. There are manufactures of doors and sashes, tools, harness and carriages. It is governed by common council of eight members, elected yearly. First settled in 1831, became a borough in 1855, incorporated in 1885. Pop. (1900) 4,519.

W. S. Kennedy,
Editor 'Recorder.'

Albion, N. Y., the county-seat of Orleans County, on the New York Central R.R. and the Erie Canal, about 43 m. northeast of Buffalo. It has two banks, public parks, a free library, several schools and churches, and 5 newspapers. The House of Refuge for Women is located here. The most important manufactures are mowing-machines, carriages, shoes, and plows. There are large stone quarries here and several fruit canneries. The city is lighted by electricity. The affairs of the community are administered by a mayor and board of trustees. Albion was first settled in 1812, incorporated 1828. Pop. (1900) 5,749.

Albion, New. See New Albion.

Albion College, a coeducational institution in Albion, Mich., organized under the auspices of the Methodist Episcopal Church. Professors and instructors, 25; students, 454; volumes in the library, 15,000; grounds and buildings valued at $80,000; productive funds, $228,000; income, $29,000; graduates, 986.

Albite, an important member of the feldspar group of minerals. It stands at one end of the albite-anorthite series of triclinic feldspars (see Feldspar Group). It is a sodium-aluminum silicate, $Na\ Al\ Si_3O_8$, and is often called «soda feldspar.» It has perfect basal cleavage and also cleaves easily parallel to the brachypinacoid. It is brittle, breaking with an uneven to conchoidal fracture. Its hardness is 6 to 6.5, and specific gravity about 2.63. Its usual color is white, whence its name (from «albus,» white), but it is occasionally gray or tinted with blue, green or red. The variety peristerite shows a delicate blue irridescence, similar to the «change of colors» of moonstone, which is also sometimes a variety of albite. Cleavelandite is a common lamellar variety, named in honor of the eminent mineralogist, Dr. P. Cleaveland, who died in 1858. Albite crystals present a great variety of forms, some of the simpler of which are quite similar to those of the monoclinic orthoclase, with which albite is often associated in parallel growths and intergrowths such as perthite. Twinning is even more common in albite than in orthoclase, and their analogy is shown by the occurrence of Carlsbad, Baveno and Manebach twins. Several other laws of twinning are, however, followed by albite, notably those known as the «albite law» and the «pericline law.» Both of these types are very common and often manifest themselves by the polysynthetic twinning lamellæ which are so characteristic of the plagioclase feldspars. Albite often occurs in tabular crystals and embedded masses in which this twinning is revealed by striations on the basal plane. Probably the most striking occurrence of albite is at Amelia, Va., this locality producing large groups of tabular crystals, each over a foot in length. It usually occurs in granite or gneiss, and less frequently in the crystalline schists. It is found but rarely in volcanic rocks and in limestones. Many of the most highly prized gem minerals, such as topaz, beryl and tourmaline occur in albitic granite, while albite is often a guide mineral to columbite, allanite and other rarer minerals. It is also an essential constituent of dioryte. There are many noteworthy localities in Switzerland, the Tyrol, Cornwall and elsewhere in Europe, while it abounds throughout the Atlantic Coast States, and is found in especially attractive specimens on amazonstone in Colorado.

Albret, Jeanne d', Queen of Navarre, daughter of Henry II. of Navarre and Margaret of Valois (sister of Francis I. of France), was the mother of Henry IV. of France, and a zealous supporter of the reformed religion, which she established in her kingdom. She was b. in 1528; d. 1572. She married Antoine de Bourbon in 1548, succeeded her father on the throne of Navarre and Béarn in 1555, reigned in conjunction with her husband till his death in 1562, and afterward alone.

Albright, Jacob, American minister of the Methodist Church: b. near Pottstown, Pa., 1 May 1759; d. 1808. His work lay among the Germans of Pennsylvania. Becoming impressed with the decline of religious life and of the doctrines and morals of the surrounding churches, he began a work of reform in 1790. He traveled about the country at his own expense, preaching his mission, until he founded in 1800 the Evangelical Association (q.v.), often known as «Albrights.»

Albufera, a lake about 9 miles square near Valencia, Spain, supposed to have been excavated by the Moors. It is separated from the sea

by a strip of land. The revenues from the fisheries of the lake belonged at one time to the Duke of Wellington.

Albula, a Swiss river in the Canton Grisons, an affluent of the Rhine, 29 m. in length, in which distance it falls over 4,500 feet.

Albula Pass, at the head of the Albula Valley, about 7,600 ft. above the sea. In this pass is the most direct road from the valley of the Inn to the valley of the Hiter-Rhein. A railroad now runs through it.

Album, among the Romans, a board or tablet on which official notices, such as the prætor's edicts, lists of the members of public bodies, etc., were written, and which was put up in some public place to be seen by all. It was so called either because it was of a white material (*albus,* white) or a material whitened, or because the writing on it was in white. Album is a name now generally given to a blank book for the reception of pieces of poetry, autographs, engravings, photographs, etc.

Albu'men, or **Albumin** (L., from *albus,* white), a substance, or rather group of substances, so named from the Latin for the white of an egg, which is one of its most abundant known forms. It may be taken as the type of the protein compounds or the nitrogenous class of food stuffs. One variety enters largely into the composition of the animal fluids and solids, is coagulable by heat at and above 160°, and is composed of carbon, hydrogen, nitrogen, and oxygen, with a little sulphur. It abounds in the serum of the blood, the vitreous and crystalline humors of the eye, the fluid of dropsy, the substance called coagulable lymph, in nutritive matters, the juice of flesh, etc. The blood contains about 7 per cent of albumen. When albumen coagulates in any fluid it readily incloses any substances that may be suspended in the fluid. Hence it is used to clarify syrupy liquors. In cookery white of eggs is employed for clarifying, but in large operations like sugar-refining the serum of blood is used. From its being coagulable by various salts, and especially by corrosive sublimate, with which it forms an insoluble compound, white of egg is a convenient antidote in cases of poisoning by that substance. With lime it forms a cement to mend broken ware.

In Botany.—A substance interposed between the embryo and the testa of many plants. It is sometimes soft and fleshy, and at other times hard. It varies greatly in amount in those plants in which it is present, being particularly large in some endogens, such as the cocoanut, in which it constitutes the eatable part of the fruit.

In Photography.—A process by which albumen is used instead of collodion to coat glass or paper. A method of doing this in the case of glass was published by M. Nièpce de Saint Victor in the 'Technologist' for 1848. It was subsequently improved by M. le Gray. The foreign transparent stereoscopic views were at one time obtained by the use of albumen in the way now described.

Albuminoid. See PROTEIDS.

Albuminuria, a condition characterized by the presence of albumen in the urine, irrespective of any organic disease of the kidney. Thus there may be a functional or physiological albuminuria, following excessive exercise, such as bicycling; febrile albuminuria as a result of fever, being especially common in malaria, pneumonia, diphtheria, and typhoid; hemic albuminuria accompanying blood diseases, lukemia, anæmia, poisoning by lead and mercury, syphilis, etc. Any of these albuminurias may result in chronic disease. See KIDNEYS.

Albunol, a town of southern Spain, in the province of Granada, near the Mediterranean, on which it has a harbor, some 35 m. to the south of the city of Granada. Pop. 9,400.

Albuquerque, Affonso d', al'bö-kärk'e, «the Great,» Viceroy of the Indies: b. near Lisbon, 1453; d. in Goa, 16 Dec. 1515. The Portuguese had discovered and subjugated a great part of the western coast of Africa, and were beginning to extend their dominion over the seas and the people of India. Albuquerque, being appointed viceroy of these new possessions, with a fleet and some troops landed on the Malabar coast in 1503; conquered Goa, which he made the seat of the Portuguese government and the centre of its Asiatic commerce; and afterward Ceylon, the Sunda Isles, the Peninsula of Malacca, and the island of Ormuz at the entrance of the Persian Gulf. When the king of Persia sent for the tribute which the princes of this island had formerly rendered to him, Albuquerque presented bullets and swords to the ambassador, saying: «This is the coin in which Portugal pays her tribute.» He made the Portuguese name profoundly respected among the princes and people of the East; and many of them, especially the kings of Siam and Pegu, sought his alliance and protection. He maintained strict military discipline, was active, far-seeing, wise, humane, and equitable, respected and feared by his neighbors while beloved by his subjects. His virtues made such an impression on the Indian peoples that, long after his death, they resorted to his grave to implore his protection against the misgovernment of his successors. Yet he did not escape the envy of courtiers and the suspicions of his king, who appointed Soarez, a personal enemy of Albuquerque, to supersede him as viceroy. This news reached him just as he was leaving Ormuz, and gave a severe shock to his shattered health and he died a few days later.

Albuquerque, al'be-kerk, N. M., town and county-seat of Bernalillo co.; situated on the Rio Grande and the Atchison, T. & S. F. and the Santa Fé Pacific R.R.'s: 75 m. S.W. of Santa Fé. It has an elevation of 5,000 feet above sea-level; is an ancient and interesting settlement, divided into the Old and New towns; and is the seat of the University of New Mexico and of a government school for Indians. The town is located in a rich gold, silver, iron, and coal mining region, and has also an extensive trade in hides, grain, wool, and wine. There are a number of railroad shops, a foundry and machine works, a national bank (capital about $150,000), and large trading and jobbing interests. Pop. (1900) 6,238.

Albur'num, the soft white substance which, in trees, is found between the liber or inner bark and the wood, and, in progress of time acquiring solidity, becomes itself the wood. A new layer of wood, or rather of alburnum, is added annually to the tree in every part just under the bark.

Alcala, name of seven cities in Spain, but by far the most important in Spanish history is Alcala de Henares, province of Toledo. Cardinal Ximines began the first building of the University of Alcala in 1500. Francis I., in 1517, declared that the cardinal had done for Spain what it had taken many kings to do for France. It was in Alcala that the famous Complutensian Polyglot Bible was brought forth.

Alchemist, The, a satirical comedy by Ben Jonson; probably his greatest work. It was played in 1610, and published in 1612. Its subject is the paramount folly of the time, the search for the philosopher's stone. The Alchemist is the quack Subtle, who, previous to exposure deludes the credulous characters of the play, the chief of whom is Sir Epicure Mammon.

Alchemy, or **Alchymy,** the art which in former times occupied the place of and paved the way for the modern science of chemistry (as astrology did for astronomy), but whose aims were not scientific, being confined solely to the discovery of the means of indefinitely prolonging human life, and of transmuting the baser metals into gold and silver. Probably the ancient nations, in their first attempts to melt metals, observing that the composition of different metals produced masses of a color unlike either — for instance, that a mixture like gold resulted from the melting together of copper and zinc — arrived at the conclusion that one metal could be changed into another. At an early period the desire of gold and silver grew strong as luxury increased, and men indulged the hope of obtaining these rarer metals from the more common. At the same time the love of life led to the idea of finding a remedy against all diseases, a means of lessening the infirmities of age, of renewing youth, and repelling death. The hope of realizing these ideas prompted the efforts of several men, who taught their doctrines through mystical images and symbols. To transmute metals they thought it necessary to find a substitute which, containing the original principle of all matter, should possess the power of dissolving all into its elements. This general solvent or *menstruum universale*, which at the same time was to possess the power of removing all the seeds of disease out of the human body and renewing life, was called the philosopher's stone, *lapis philosophorum*, and its pretended possessors adepts. The more obscure the ideas which the alchemists themselves had of the appearances occurring in their experiments, the more they endeavored to express themselves in symbolical language. Afterward they retained this phraseology to conceal their secrets from the uninitiated. In Egypt Hermes Trismegistus was said to have left behind him many books of chemical, magical, and alchemical learning. These, however, are of a later date. (See HERMES TRISMEGISTUS.) After him chemistry and alchemy received the name of the hermetic art. It is certain that the ancient Egyptians possessed considerable chemical and metallurgical knowledge, although the origin of alchemy cannot with certainty be attributed to them. Several Grecians became acquainted with the writings of the Egyptians, and initiated in their chemical knowledge. The fondness for magic, and for alchemy more particularly, spread afterward among the Romans also. When true science was persecuted under the Roman tyrants, superstition and false philosophy flourished the more. The prodigality of the Romans excited the desire for gold, and led them to pursue the art which promised it instantaneously and abundantly. Caligula made experiments with a view of obtaining gold from orpiment. On the other hand, Diocletian ordered all books to be burned that taught to manufacture gold and silver by alchemy. At that time many books on alchemy were written, and falsely inscribed with the names of renowned men of antiquity. Thus a number of writings were ascribed to Democritus, and more to Hermes, which were written by Egyptian monks and hermits, and which, as the Tabula Smaragdina, taught in allegories, with mystical and symbolical figures, the way to discover the philosopher's stone. At a later period chemistry and alchemy were cultivated among the Arabians. In the 8th century the first chemist, commonly said to be Geber, flourished among them, in whose works rules are given for preparing quicksilver and other metals. In the Middle Ages the monks devoted themselves to alchemy, although they were afterward prohibited from studying it by the popes. But there was one even among these, John XXII., who was fond of alchemy. Raymond Lully, or Lullius, was one of the most famous alchemists in the 13th and 14th centuries. A story is told of him that during his stay in London he changed for King Edward I. a mass of 50,000 pounds of quicksilver into gold, of which the first rose-nobles were coined. The study of alchemy was prohibited at Venice in 1488. Paracelsus, who was highly celebrated about 1525, belongs to the renowned alchemists, as do Roger Bacon, Basilius Valentinus, and many others. When, however, more rational principles of chemistry and philosophy began to be diffused and to shed light on chemical phenomena, the rage for alchemy gradually decreased, though many persons, including some nobles, still remained devoted to it. Alchemy has, however, afforded some service to chemistry, and even to medicine. Chemistry was first carefully studied by the alchemists, to whose labor and patience we are indebted for several useful discoveries, for example, various preparations of quicksilver, kermes, etc.

It is still impossible to assert anything with certainty about the transmutation of metals. Modern chemistry, indeed, places metals in the class of elements, and denies the possibility of changing an inferior metal into gold. Most of the accounts of such transmutation rest on fraud or delusion, although some of them are accompanied with circumstances and testimony which render them probable. By means of the galvanic battery even the alkalies have been discovered to have a metallic base. The possibility of obtaining metal from other substances which contain the ingredients composing it, and of changing one metal into another, or rather of refining it, must therefore be left undecided. Nor are all alchemists to be considered impostors. Many have labored, under the conviction of the possibility of obtaining their object, with indefatigable patience and purity of heart (which is earnestly recommended by sound alchemists as the principal requisite for the success of their labors). Designing men, however, have often

used alchemy as a mask for their covetousness, and as a means of defrauding silly people of their money. Many persons even in our days, destitute of sound chemical knowledge, have been led by old books on alchemy, which they did not understand, into long, expensive, and fruitless labors. Hitherto chemistry has not succeeded in unfolding the principles by which metals are formed, the laws of their production, their growth and refinement, and in aiding or imitating this process of nature; consequently the labor of the alchemist is but a groping in the dark.

Alciati, Andrea, Italian jurist and poet: b. Milan, 8 May 1492; d. Pavia, 12 Jan. 1550. For many years an advocate in Milan, he treated the objects of legal science to keen criticism, and was founder of the so-called « elegant» school of law. He also wrote several antiquarian and historical essays, but his most popular work was the ‹ Emblems › (Milan 1522), epigrammatic poems on his contemporaries' virtues and vices. Of the numerous editions of this work several are chiefly sought on account of their wood-engravings. Editions of his ‹ Complete Works › in Latin: 4 vols. Basle, 1546–9; 6 vols. Lyons, 1560–1; 4 vols. Frankfort, 1617. Cf. C. Mignault's ‹ Life of Alciati › (Milan, 1584).

Alcibiades, son of Cleinias, an Athenian of high family: b. in Athens 450 B.C.; d. 404 B.C. His father, who died a few years after his birth, had greatly distinguished himself in the Persian wars, and had taken a prominent part in the expulsion of the Peisistratidæ. Alcibiades was a relation of Pericles, who was his joint guardian along with Ariphron. He was remarkable in youth for the beauty of his person, the dissoluteness of his manners, the determination of his character, and the greatness of his abilities. He came under the influence of Socrates, who tried to lead him into the paths of virtue; but though their friendship was strengthened by mutual obligations, each having saved the other in battle, the passions of Alcibiades were too strong for advice, and little permanent effect was produced on his character. He acquired great popularity by his liberality in providing for the amusements of the people, and although guilty of many violent, extravagant, and audacious acts, he had, after the death of Cleon, a political ascendency which left him no rival but Nicias. Both at first cultivated alliance with Sparta, to which Alcibiades had a hereditary partiality, but the Spartans trusting more to Nicias, he was offended, and induced the Athenians to break with Sparta and ally themselves with Argos, Elis, and Mantineia (in the Peloponnesian war). In 419 he was chosen *strategos,* and led a small army into the Peloponnesus with which some important operations were effected. In 415 he advocated the Sicilian war, and was chosen one of the leaders of the expedition appointed to conduct it; but before it sailed he was charged with profaning and divulging the Eleusinian mysteries, and mutilating the busts of Hermes which were set up in public all through Athens. He was permitted to take his place in the expedition, but was recalled before his plans could be accomplished. He made his escape and went to Sparta, where he was well received. He divulged the plans of the Athenians, and assisted the Spartans to defeat them. Sentence of death and confiscation was pronounced against him at Athens, and he was cursed by the ministers of religion. He induced the Athenian dependencies of Athens to revolt, and made alliance with Tissaphernes, a Persian satrap. Soon after he abandoned Sparta and took refuge with the Persian, ingratiating himself by his affectation of Persian manners as he had previously done at Sparta by a similar affectation of Spartan simplicity. He now began to intrigue for his return to Athens, offering to bring Tissaphernes over to the Athenian alliance. His intrigue led to the establishment of an oligarchy (the Four Hundred), but they did not recall him. The fleet, however, which was stationed at Samos declared in favor of a democracy and recalled him. The revolution was effected at Athens without the return of the armament, and the banishment of Alcibiades was cancelled. He remained abroad, however, for some years in command of the Athenian forces, gained several victories, and took Chalcedon and Byzantium. In 407 B.C. he returned to Athens, where all proceedings against him were cancelled, but in 406, the fleet which he commanded having suffered a severe defeat, he was deprived of his command. He retired to the Thracian Chersonesus, where he made war with mercenaries on the Thracian tribes. On the establishment of the Thirty at Athens a decree of banishment was passed against him. He took refuge with Pharnabazus, a Persian satrap, and was about to proceed to the court of Persia when he was assassinated, probably through private revenge.

Alcinous, said to have been a king of the Phæacians, in the island now called Corfu. See ULYSSES.

Alciphron, al'si-frŏn, a Greek rhetorician who flourished in the 2d century of the Christian era and attained celebrity through his series of more than a hundred imaginary letters purporting to be written by the very dregs of the Athenian population, including courtesans and petty rogues. Their importance in literature is due almost wholly to the insight they afford into the social conditions and manners and morals of the day. The letters from the courtesans (*hetairai*) are based upon incidents in Menander's lost plays, and the new Attic comedy was likewise drawn upon for material.

Alciphron, or **The Minute Philosopher.** See BERKELEY, BISHOP.

Alcira, a well-built and strongly-fortified town of Spain, in the province of Valencia, on an island encircled by two arms of the river Jucar, some 25 m. from Valencia. It was founded by the Carthaginians. Pop. 20,000.

Alcmæon, alk-mē'on, a son of Amphiaraus and Eriphyle, was one of the heroes who took part in the successful expedition of the Epigoni against Thebes. He was charged by his father to put his mother to death in revenge for her having urged her husband to take part in an expedition in which his foresight showed him he should perish. She had been gained over to urge this fatal course by a gift from Polynices of the fatal necklace of Harmonia. The matricide brought upon Alcmæon madness and the horror of being haunted by the Furies, but at Psophis he was purified by Phegeus, whose daughter he married, giving her the fatal

present. But the land became barren in consequence of his presence, and he fled to the mouth of the river Achelous, the god of which gave him his daughter Callirrhoë in marriage. His new wife longed for the fatal necklace, and sent her husband to Psophis to procure it under the pretence of dedicating it at Delhi; but Phegeus, learning for whom it was really intended, caused his sons to murder the ill-fated Alcmæon.

Alcman, one of the earliest and greatest of Greek lyric poets, belonging to the 7th century B.C. He is supposed to have been a native of Lydia, and to have been taken as a slave to Sparta. Only small fragments of his odes remain. He used the broad, homely Doric dialect. His poems were love ditties, hymns, pæans, processional chants, etc.

Alcmene, or **Alkmene,** alk-mē'nē, in Greek mythology, the daughter of Anaxo and Electryon, king of Mycenæ. She became the mother of Hercules through Zeus, who took the form of her husband Amphitryon. Finally Zeus bade Hermes guide her to the Islands of the Blest, where she was happily united with Rhadamanthus.

Alco, a small variety of dog, with a small head and large pendulous ears, found wild in Mexico and Peru, and also domesticated.

Alcobaça, a small town of Portugal, in Estremadura, 50 m. N. of Lisbon, at the junction of the Alcoa and Baça; is celebrated for a magnificent Cistercian monastery, the richest in the kingdom. It was founded in 1148 by Don Alphonso I. The buildings include an early Gothic church, containing the tombs of some of the Portuguese kings. The library is said to possess more than 25,000 volumes. Parts of the buildings are used for barracks.

Alcock, Sir Rutherford, diplomat: b. Ealing, 1809; d. London, 2 Nov. 1897. Educated as a physician, he served as surgeon with British troops in Spain and Portugal 1832–6; and was appointed consul at Fuchow 1844. On the way his services were requisitioned at Amoy, where, with Sir Harry Parkes, he succeeded in convincing the Chinese officials that treaty agreements were to be respected and kept. Transferred to Shanghai he showed courage and determination by proclaiming that English ships would pay no duties, and that 1,400 grain junks then waiting to sail would not be allowed to go until the murderers of some missionaries were seized and punished. Though only one British sloop of war was in the harbor at the time, his bold attitude succeeded. He was appointed first consul-general in Japan 1858, and created K. C. B. 1862. As minister at Peking (1865) he conducted many difficult negotiations with tact and success. Retiring in 1871, he devoted himself to medical charities, promotion of geographical studies, and the furtherance of a knowledge of Japanese art. Works: 'Medical History and Statistics of the British Legion in Spain' (1838); 'Japanese Grammar' (1861); 'Capital of the Tycoon' (1863); 'Art and Art Industries in Japan' (1878).

Alcofribas Nasier, pseudonym sometimes used by Rabelais (q.v.).

Al'cohol. (Origin of the word somewhat obscure. According to most authorities it is from the Arabic ***al-koh'l, koh'l*** being the finely-powdered black sulphid of antimony used in the East for painting the eyebrows. First used to signify this powder, it afterward stood for any fine powder obtained by trituration or sublimation; then for any essence or spirit, and lastly for the liquid to which it is now applied. In the latter part of the 16th century spirit dried over powdered carbonate of potash was called *spiritus alcolisatus;* but Kopp suggests that this is a corruption of *spiritus alcalisatus*, signifying spirit that has been treated with alkali, and that alcolized [or alcoholized] spirit was then shortened to alcohol.)

1. *Ethyl Alcohol.*— Unless otherwise qualified, «alcohol» is understood to mean the liquid known to the chemist as «ethyl alcohol,» and to the trade as «grain alcohol,» or «spirits of wine.» It is colorless and inflammable, burning with a flame that is intensely hot but almost non-luminous. Most of the alcohol used in the arts is produced by the fermentation of sugars or starches. A thin paste is made from molasses, finely ground corn or potatoes, or other natural products containing sugars or starches, and a small quantity of malt or other agent containing diastase (q.v.) is added. The mixture is then allowed to stand until the diastase has transformed the starch into dextrose (glucose). Taking the chemical formula of starch as $(C_6H_{10}O_5)_3$ for the sake of illustration, we may have either of the following reactions as the primary effect of the diastase:

$$\underset{\text{Starch}}{(C_6H_{10}O_5)_3} + \underset{\text{Water}}{H_2O} = \underset{\text{Dextrin}}{(C_6H_{10}O_5)_2} + \underset{\text{Dextrose}}{C_6H_{12}O_6}$$

$$\underset{\text{Starch}}{(C_6H_{10}O_5)_3} + \underset{\text{Water}}{2H_2O} = \underset{\text{Maltose}}{C_{12}H_{22}O_{11}} + \underset{\text{Dextrose}}{C_6H_{12}O_6}$$

Neither dextrin nor maltose is directly fermentable, but each slowly becomes further transformed into dextrose, as appears from the following equations:

$$\underset{\text{Dextrin}}{(C_6H_{10}O_5)_2} + \underset{\text{Water}}{2H_2O} = \underset{\text{Dextrose}}{2C_6H_{12}O_6}$$

$$\underset{\text{Maltose}}{C_{12}H_{22}O_{11}} + \underset{\text{Water}}{H_2O} = \underset{\text{Dextrose}}{2C_6H_{12}O_6}$$

The reduction to dextrose (glucose) being now complete, yeast is added, and the temperature is maintained at from 72° to 85° F. Under the influence of the yeast-plant (*Saccharomyces cerevisiæ* or *Torula cerevisiæ*) the dextrose then undergoes fermentation, alcohol and carbon-dioxid being the chief products, according to the equation:

$$\underset{\text{Dextrose}}{C_6H_{12}O_6} = \underset{\text{Alcohol}}{2C_2H_6O} + \underset{\text{Carbon-dioxid}}{2CO_2}$$

(A certain amount of nitrogenous and mineral matter must be present, in addition to the starch and sugar, in order to furnish food for the yeast-plant.) The next step in the process is to distil off the alcohol from the fermented product. This is usually done in a still heated by steam. One or more redistillations may be necessary in order to obtain the alcohol in a satisfactory state of purity and strength. The product of the original fermentation is weak in alcohol, but the subsequent distillations effect a great concentration, since alcohol is far more volatile than water and therefore passes off first. The British Pharmacopœia requires rectified spirits (produced as described above) to

have a specific gravity of 0.838, which is equivalent to 84 per cent of alcohol by weight. The United States Pharmacopœia fixes the specific gravity at 0.820, which corresponds to 91 per cent of alcohol by weight. It is possible to obtain this latter degree of concentration by ordinary distillation; but it is not possible to free the alcohol entirely from water without distilling it with potassium-carbonate, quicklime, calcium-chloride, or some similar substance possessing sufficient affinity for water to prevent the water from passing over. The best way to eliminate the last traces of water is to digest strong alcohol with quicklime for two hours at about 100° F., and then distil, rejecting the first and last portions of the distillate. The product is then subjected to the same treatment a second time, after which it will probably be free from water. Alcohol thus deprived of the last trace of water is termed « absolute » or « anhydrous » alcohol. Its chemical formula is $C_2H_5.OH$, and its specific gravity is 0.80625 at 32° F., and 0.79367 at 59° F. Absolute alcohol boils at 173.1° F., when the barometer stands at 29.92 inches (760 mm.). It freezes at about 200° below zero F., first becoming very viscid. Its low freezing-point has led to its use as a thermometric fluid for the measurement of low temperatures. Its specific heat is variously estimated, but is in the vicinity of 0.61. Absolute alcohol has a powerful affinity for water, and it is therefore used as an astringent, and (for certain purposes) as an antiseptic. When exposed to the air it quickly absorbs a sensible amount of aqueous vapor, and ceases to be « absolute.» According to the experiments of Atwater, the human body is capable of oxidizing about two ounces of it per day, since this amount can be administered without any evidence of alcohol appearing in the excreta. Alcohol mixes with water in all proportions, and is extensively used as a solvent for substances that do not dissolve in water: notably for organic substances and for alkaloids and drugs. When absolute alcohol is mixed with water the volume of the mixture is considerably less than the sum of the volumes of the constituents. The specific gravity of such a mixture therefore cannot be deduced by any simple formula; but it has been found by direct experiment, and tabulated, for all possible mixtures and temperatures. The strength of a given mixture of alcohol and water may be found by observing the specific gravity of the mixture at a definite temperature by means of a hydrometer (q.v.) and then referring to the tables. The greatest contraction of volume observed upon mixing absolute alcohol and water occurs when 49.8 volumes of water are mixed with 53.9 volumes of absolute alcohol, both liquids being at 32° F. The volume of the mixture is then 100, instead of 103.7, as it would be if there were no contraction. Mendeléeff points out that this particular mixture corresponds to a possible compound having the formula $C_2H_6O.3H_2O$; but it has not been conclusively proved that such compound exists. An alcohol containing 49.3 per cent (by weight) of absolute alcohol is known in the arts and for excise purposes as « proof spirit.» This term was originally intended to denote alcohol just strong enough to ignite gunpowder when burned upon it; but it was defined by law in the reign of George III. of England to be spirit « such as shall, at the temperature of 51° F., weigh exactly twelve-thirteenth parts of an equal amount of distilled water » (Watts). At 60° F. proof spirit has a specific gravity of 0.920. A mixture stronger or weaker than this is said to be (respectively) overproof or underproof. Distilled liquors, such as whiskey, brandy, and gin, contain from 40 to 50 per cent of absolute alcohol, wines from 7 to 20, ale and porter from 5 to 7, and beer from 2 to 10. Alcohol coagulates albumen, and, partly for this reason and partly because of its action in arresting the development of micro-organisms, it prevents the putrefaction of dead animal matter. The alkali metals attack absolute alcohol rapidly with the formation of compounds variously known as alcoholates, alcohates, and alcoates, but more definitely and correctly as « ethylates.» Thus alcohol may be regarded as water in which one atom of hydrogen has been replaced by a molecule of the organic radical ethyl, C_2H_5, and, water being H-O-H, the formula for alcohol may be written (C_2H_5)-O-H. An alkali metal, when it combines with alcohol, merely replaces the H at the right of this formula; and sodium ethylate (for example) is therefore (C_2H_5)-O-Na, or simply C_2H_5ONa. The commonest test for alcohol in small quantities consists in warming the suspected liquid (or its distillate) with caustic potash and iodine. If alcohol is present iodoform comes down after a time as a precipitate. In England the use of alcohol in the arts is permitted without the payment of an excise tax, provided the alcohol contains 10 per cent of methyl alcohol (wood spirit). Alcohol so treated is known as « methylated spirit »; it is unfit for drinking, and the methyl alcohol that it contains cannot be readily removed. Alcohol can be prepared directly from its elements as follows: Acetylene (q.v.), C_2H_2, will combine directly with hydrogen to form olefiant gas, C_2H_4; concentrated sulphuric acid will absorb olefiant gas with the formation of hydrogen-ethyl-sulphate, $C_2H_5.HSO_4$; and if the product so obtained is diluted with water and boiled, alcohol is formed in accordance with the equation:

$$C_2H_5.HSO_4 + H_2O = H_2SO_4 + C_2H_5.OH.$$

This process is of considerable theoretic interest, and is said to be in commercial use in Russia. Until carbide of calcium (from which acetylene is prepared) can be had more cheaply, however, it can hardly be successfully used in the United States.

2. *Wood Alcohol, or Methyl Alcohol.*— A colorless, inflammable liquid, strongly resembling ethyl alcohol in its general properties. It burns with a flame resembling that of grain alcohol, but with sensibly less evolution of heat. It is far cheaper than grain alcohol, because there is no excise tax upon it; in many uses it may be substituted for grain alcohol with success, its solvent powers being very similar. It cannot be used internally, however, as it is of a poisonous nature, and has a peculiar selective action upon the optic nerve, in which it often induces a condition of permanent atrophy with consequent total blindness. Methyl alcohol is obtained by the dry distillation of wood. The process, as carried out in New York State, is substantially as follows: Hardwood is cut into cordwood size and allowed to season thoroughly,

two-year-old wood being dry enough to yield excellent results. Beech, maple, and birch are most commonly used, birch being the poorest of the three, because it yields a larger proportion of objectionable tarry matter. The seasoned wood is placed in retorts of cast iron or sheet steel, which are cylindrical in general shape, and large enough to hold rather more than half a cord each. A slow fire is then built under the retorts, its intensity being gradually increased as the distillation progresses, and regulated so that at the end of from 12 to 18 hours nothing remains in the retort but charcoal. The distillate is passed through a condenser, by which a portion is condensed into a watery fluid, while another and very considerable portion passes through in the form of a permanent, non-condensable gas. The non-condensable part consists largely of marsh gas, hydrogen, carbon-dioxid, and carbon-monoxid, together with smaller amounts of acetylene and numerous other substances. No attempt is made to utilize this portion of the product except as fuel. The portion that condenses consists largely of acetic acid and methyl alcohol, together with acetate of methyl and acetone, and a considerable quantity of tarry matter. The condensed distillate is passed into settling-tanks, where it is allowed to remain until the greater part of the tarry matter has subsided. The lighter part is then drawn off and saturated with slaked lime to fix the acetic acid. A second distillation expels the methyl alcohol, which is recovered by means of a condenser and shipped to the refiners in iron tanks, being known to the trade in this form as « wood spirit.» The acetate of lime remaining behind is then recovered by evaporation and spread out upon a heated floor to dry.

Acetate of lime, as it comes from the alcohol manufacturer, is brown in color, from the tarry impurities that it contains. It is used in the manufacture of acetic acid and the various acetates (notably those of iron and aluminum) that are used in dyeing and in printing upon cloth. The impure methyl alcohol, or « wood spirit,» that is shipped from the factory to the refiner, usually contains 80 per cent of alcohol and 20 per cent of water. The yield of spirit of this strength varies greatly, according to the skill and care exercised by the manufacturer; but in the best plants it may be taken at from eight to nine gallons per cord of good wood. Crude wood spirit contains considerable empyreumatic matter as well as acetone, acetate of methyl, and acetate of ammonia. Pure methyl alcohol may be prepared by saturating the crude spirit with fused calcium chloride ($CaCl_2$) and heating on a water-bath. Methyl alcohol combines with calcium chloride, under these conditions forming a compound which can be readily purified, and from which the alcohol can again be recovered by distilling with water. A final distillation over quicklime will give the alcohol in its anhydrous or « absolute » state. Pure methyl alcohol, free from water, has a specific gravity at 32° F. of 0.8101. Its chemical formula is $CH_3.OH$; it is the hydrate of the organic radical « methyl » (CH_3), being analogous in this respect to ethyl alcohol, which is the hydrate of the organic radical « ethyl » (C_2H_5). It boils at about 151° F. under ordinary atmospheric pressure.

3. *Alcohol.*— In organic chemistry, a member of a numerous class of compounds consisting of carbon, hydrogen, and oxygen, and derived from hydrocarbons containing an even number of hydrogen atoms by the substitution of one or more hydroxyl molecules (HO) for an equal number of hydrogen atoms. The alcohols, as thus defined, include the two substances described above, and also many others (such as glycerin) whose properties at first sight appear to be radically different from those of either ethyl or methyl alcohol. Alcohols are classified as monohydric, dihydric, trihydric, tetrahydric, pentahydric, and hexahydric, according as they contain one, two, three, four, five, or six molecules of hydroxyl (OH). Thus ethyl alcohol, C_2H_5OH, is monohydric, while glycerin, $C_3H_5.(OH)_3$, is trihydric. In the present article only the monohydric alcohols will be considered. These are divisible into five general series as follows: (*a*) Those having the general formula $C_nH_{2n+1}.OH$; they are derived from the paraffins, C_nH_{2n+2}, by the substitution of one molecule of OH for one atom of hydrogen, and are known as the « fatty alcohols.» (*b*) Those having the formula $C_nH_{2n-1}.OH$. Allyl alcohol is the most familiar member of this series. Its formula is $C_3H_5.OH$. (*c*) Those having the general formula $C_nH_{2n-3}.OH$. No familiar example can be given. (*d*) Those having the general formula $C_nH_{2n-7}.OH$. This series is derived from the aromatic series of hydrocarbons, just as the first series given above is derived from the paraffins. Thus, when hydrogen peroxid, H_2O_2, acts upon benzene, C_6H_6, we have $C_6H_6 + H_2O_2 = H_2O + C_6H_5.OH$, the last expression in this equation being the formula of phenyl alcohol, or (as it is more familiarly known) carbolic acid. (*e*) Those having the general formula $C_nH_{2n-9}.OH$. Cholesterin belongs to this series. It will be evident that the complete discussion of even the monohydric alcohols would be impossible in the present place; hence in what follows attention will be confined to the fatty or paraffin series of monohydric alcohols, having the general formula $C_nH_{2n+1}.OH$. No less than 17 distinct members of this series are known, the first five, when they are arranged in order according to the number of carbon atoms they contain, being:

Methyl alcohol, $CH_3.OH$.
Ethyl alcohol, $C_2H_5.OH$.
Propyl alcohol, $C_3H_7.OH$.
Butyl alcohol, $C_4H_9.OH$.
Amyl alcohol, $C_5H_{11}.OH$.

The first two members of this series do not admit of any isomeric modifications; but the third member admits of one such modification, and the following members admit of more than one. For example, propane has the formula $CH_3.CH_2.CH_3$, and an alcohol may be formed by substituting OH for any one of the H atoms in this formula. If a hydrogen atom at the end of the formula be replaced in this way, we shall obtain the same result whether the substitution be made at the right-hand end or the left; that much is evident from the symmetry of the formula. But if one of the hydrogen atoms in the central CH_2 be so replaced, the alcohol thus formed may differ from the one previously obtained by an end substitution; and in fact ex-

periment shows that two different alcohols do actually exist, both having the same formula C_3H_7OH. These are distinguished as «primary» and «secondary» respectively. In general, an alcohol is called «primary» if the carbon atom to which the OH is attached is itself attached to only one other carbon atom; it is «secondary» if the carbon atom to which the OH is attached is itself attached to two other carbon atoms; and it is «tertiary» if this carbon atom is attached to three other carbon atoms. If it is admitted that the quantivalence of carbon is never greater than four, it follows that no carbon atom can be attached to more than three other carbon atoms; hence every alcohol in the class under consideration must be either primary, secondary, or tertiary. The various radicals with which hydroxyl (OH) is combined in the alcohols are collectively called alkyls. Thus CH_3 (methyl), C_2H_5 (ethyl), and C_3H_7 (propyl) are all «alkyls,» and an alcohol may be briefly described as the hydrate of an alkyl. Other alkyl compounds are also known. For example, hydrochloric, hydrobromic, hydriodic, or hydrofluoric acid, when allowed to act upon an alkyl hydrate, yields the chloride, bromide, iodide, or fluoride of that alkyl. Thus: $CH_3.OH + HCl = CH_3.Cl + H_2O$; and $C_3H_7.OH + HI = C_3H_7.I + H_2O$. $CH_3.Cl$ is «methyl chloride,» and $C_3H_7.I$ is «propyl iodide.» The oxids of alkyls are called «simple ethers.» (See ETHER.) For example, $(C_2H_5)_2.O$ is ethyl oxid (or ether), often erroneously called «sulphuric ether» from the fact that sulphuric acid is used in preparing it. By the action of various acids upon alkyl hydrates (or alcohols), salts of these alkyls, entirely analogous to the metallic salts, are obtained. Thus acetic acid and ethyl alcohol react according to the equation:

$$C_2H_5.OH + CH_3.COOH = CH_3.COO(C_2H_5) + H_2O.$$

Ethyl hydrate	Acetic acid	Ethyl acetate	Water

This reaction is entirely analogous to the following familiar one relating to potassium:

$$K.OH + CH_3.COOH = CH_3.COOK + H_2O.$$

Potassium hydrate	Acetic acid	Potassium acetate	Water

Alcoholism, a term applied to the symptoms produced by poisoning with ethyl alcohol (see ALCOHOL). Alcoholism may be *acute, subacute* or *chronic,* and in order to understand its phases a brief review of the more important features of the physiological action of alcohol is necessary. Locally alcohol is an irritant, and induces congestion and increased cellular activity. There appears to be some foundation for the popular view that taken before a meal alcohol increases the appetite and digestive power, for although in any marked quantity it greatly reduces or altogether inhibits the action of the digestive ferments it is probable that the increased amount of gastric juice secreted under the influence of small amounts more than makes up for this effect. Some authorities maintain that while the stimulant remains in the stomach digestion is retarded, but that after absorption of the alcohol the process advances more rapidly than would otherwise have been the case. The most important effect of the administration of alcohol is manifested by the nervous system. There is still some difference of opinion in this regard, some observers claiming that in small amounts it acts as a stimulant, whereas others assert that the apparent increase in intellectual activity is not real but is dependent on depression of the higher centres whereby the normal self control and reserve are cast off and the lower centres are allowed to act without restraint. Experiments have shown that tasks like the addition of columns of figures or reading series of disconnected syllables were less well performed when the person had taken moderate amounts of alcohol, though he usually felt increased self-confidence and was convinced that the actually inferior work he was doing was especially good. It is in this way that alcohol aids the after dinner speaker, who is by moderate amounts of wine relieved of diffidence or embarrassment and enabled to speak with a fluency never at his command under ordinary conditions. It is probable that the capacity for muscular work also is only apparently augmented by alcohol, the slight increase in efficiency at the start being neutralized by the earlier onset of fatigue. According to modern observers alcohol has but little direct effect on the circulation, though there is some change in the distribution of the blood through dilatation of the peripheral vessels. Respiration is little if at all affected. The question of whether or not alcohol is a food has elicited much controversy, but the experiments of Atwater, Neumann, and others show beyond doubt that a certain amount of alcohol can be completely burnt in the body and serve as a source of heat and energy. In this way a saving of other food stuffs is affected, and in this sense alcohol is undoubtedly a food. The view upheld by some of the older authors that alcohol has the power of lessening the oxidation of the tissues is, however, unfounded. The modern tendency is to regard alcohol not as a physiological stimulant but as a universal depressant. From the above it might be inferred that alcohol does not possess the traditional value ascribed to it in medicine, and to some extent this is true. On the other hand, there are many legitimate indications for its use that cannot be met by other drugs and few thoughtful clinicians would be willing to do without its aid. Alcohol is often used in popular medicine without a correct conception of its action. Contrary to general belief it does not raise the bodily temperature, but actually causes it to fall on account of the increased radiation of heat from the surface of the body accompanying the dilatation of the blood vessels of the skin. Consequently alcoholic drinks should not be taken before exposure with the idea of avoiding fatigue or chilling, though there is no objection to its use when the exposure is over and the individual has returned home wet or chilled through.

Acute alcoholic poisoning follows the taking of very large quantities of strong spirits in a short time, and is not often seen. The patient promptly becomes comatose, the face is congested or purplish, there is complete muscular relaxation, weak heart action, and collapse, ending in death through paralysis of the heart or

of respiration, or both, unless medical aid is given. *Subacute alcoholism* is the ordinary type of drunkenness or "intoxication" and produces different manifestations in different individuals. The first effect of moderate amounts of alcohol is to cause exhilaration, garrulity, indistinctness and incoherency of speech, blunting of the sense of touch, and loss of muscular control so that the patient is unsteady on his feet and staggers when he walks. Dizziness and disturbances of sight and hearing may also appear, and finally a deep lethargy and stupor supervene. On awaking, nausea, vomiting, headache and mental depression remind the sufferer of his debauch. In some individuals the stage of hilarity does not appear and quarrelsomeness and moroseness are manifested from the start. The insensibility of alcoholic intoxication to some extent resembles that attending certain grave disorders like apoplexy, epileptic coma, fracture of the skull, or opium poisoning, and mistakes in diagnosis on persons found unconscious in the street are unfortunately not infrequent. The true state of affairs is often extremely difficult to recognize, and it is always wiser to treat doubtful cases as if the more serious trouble existed. The fact that the breath smells of liquor is of little value, as bystanders may have sought to aid a victim of other conditions in this way, or a man who has indulged in alcohol may also be suffering from some of the difficulties mentioned. Some persons instead of becoming stuporous pass into a condition of wild excitement and uncontrollable fury termed alcoholic mania, during which the most revolting crimes may be committed. In others convulsive seizures, or alcoholic epilepsy, may succeed the first stage. Dipsomania is a form of insanity in which the patient is subject to attacks of irresistible craving for liquor, though in the intervals he may be quite rational and alcoholic beverages may even be repugnant to him. Delirium tremens is a state of nervous unrest sometimes following a protracted debauch, sometimes appearing in steady, but not necessarily excessive, drinkers, usually as the result of some physical or mental shock. There are distaste for food, intense restlessness, terrifying hallucinations and illusions, and obstinate insomnia. The treatment of acute alcoholism comprises, first, elimination of the poison by washing out the stomach, purging, rectal irrigation with salt solution, and the Turkish bath, and secondly, the substitution of other stimulants such as ammonia, strychnine, caffeine, etc., until nourishment can be retained and strength returns. In delirium tremens the two great indications are to produce sleep and nourish the patient, problems that often tax the ingenuity of the physician to the utmost.

Chronic alcoholism is the result of long continued immoderate indulgence in alcoholic liquors and is a serious cause of disease. Nearly all the organs of the body are affected and exhibit a new growth of connective tissue. The blood vessels show the lesions of arteriosclerosis, the heart is affected in a variety of ways, commonly becoming fatty and weak, the kidneys develop nephritis, the liver cirrhosis, and the stomach is the seat of a chronic catarrhal condition giving rise to nausea, vomiting and distaste for food. There are congestive and catarrhal changes in the respiratory apparatus; the bodily strength is decreased and there is a tendency to obesity. There is also marked involvement of the nervous system leading to complete mental and moral deterioration with loss of will power, loss of memory, and incapacity for the responsibilities of life. Chronic alcoholics have lessened power of resistance to infectious diseases and readily break down under the stress of any mental or physical strain. The treatment of chronic alcoholism requires isolation of the patient, preferably in an institution, where no intercourse with friends will be possible. In one plan of treatment every article of food given the patient is soaked in liquor until the disgust awakened by its odor and taste is sufficiently great to ensure abstinence for a time at least. Some authorities advise immediate withdrawal of all alcohol, others recommend a more gradual process of "tapering off." Which method is preferable depends on the individual case. Hypodermic injections of nitrate of strychnine form the basis of some of the courses of treatment.

Alcoran. See KORAN.

Alcorn, al'kern, **James Lusk,** American statesman: b. near Golconda, Ill., 4 Nov. 1816; d. 30 Dec. 1894. He was educated at Cumberland College; five years deputy sheriff of Livingston co., Ky.; member of the legislature 1843; in 1844 removed to Mississippi and began law practice, and was in the Mississippi legislature 1846–65. He was a Scott presidential elector in 1852, declined a Whig nomination for governor 1857, and the same year was defeated for Congress by L. Q. C. Lamar. He founded the levee system in the State. In 1861 he was in the Secession Convention, and was elected brigadier-general, but Jefferson Davis refused his commission from political grudge. In 1865 he was elected United States Senator, but not allowed to take his seat. In 1869 he was elected governor (Republican), but resigned on election to the United States Senate, where he served 1871–7. He was independent candidate for governor in 1873, but was defeated.

Alcott, Amos Bronson, American philosopher and educator: b. Wolcott, Conn., 29 Nov. 1799; d. 4 March 1888. In 1823 he set up an infant school, teaching it by conversation; and it gained much local fame. In 1828 he removed to Boston, and till 1836 conducted a school of the same sort, exciting wide attention by his genius for teaching, his revolutionary methods, and his exaggerated respect for the infant mind. His system was disfavored by most people, and in 1836 he removed to Concord, Mass., thenceforth expounding reform views on all human subjects, society and theology, diet and education, politics, morals, and metaphysics. He became an admired public lecturer in the great days of the lecture platform. In 1842 he visited England, where a Pestalozzian school near London had been named Alcott House. Returning with two English friends, one of them, Charles Lane, bought an estate in the town of Harvard, Mass., for a communistic

settlement, and the others joined him; but it failed. Mr. Alcott lived in Boston for a while, but finally returned to Concord, where he spent the remainder of his life as a « peripatetic philosopher,» as justly said: giving talks in different towns and cities on all human subjects when invited,— first at random, but latterly formal, with printed topics and regular places and periods. The conversation was nominally open, and questions in order; but it was soon found better to let it be a monologue by Mr. Alcott, who was put out by interruptions and could not argue. The company lost nothing; for though entirely unsystematic, and having no set philosophy which could have been developed into a school, he was fertile in ideas of deep spiritual insight and noble loftiness, and many leaders of thought, as Emerson, acknowledged him as a source of some of their best inspirations. In this characteristic of intellectual scrappiness, yet great molding influence, he may be compared with Coleridge and St. Simon. He was a leader among the Transcendentalists; and that he was an ardent Abolitionist goes without saying. His grounds in Concord represented his independence of mind and whimsicality: they were fenced by himself with gnarled pine boughs of endless diversity of form, apparently picked up as he walked. He contributed ‘Orphic Sayings’ to the *Dial*, of Boston (1839–42), and published many scattered papers; ‘Tablets’ (1868); ‘Concord Days,’ recollections of that place (1872); ‘Table Talk’ (1877); ‘Sonnets and Canzonets’ (1877).

Alcott, Louisa May, American novelist, daughter of A. B. Alcott: b. Germantown, Pa., 29 Nov. 1832; d. Boston, Mass., 6 March 1888, two days after her father. She was two years old when her parents moved to Boston; eight when they went to Concord. Her father was her chief teacher, on the system of his famous infant schools: as the latter developed no other geniuses, probably nature was responsible for hers. Thoreau also taught her for a time. She had always creative facility and sense of literary form, and began writing in early youth; at first for pleasure, then at 16 for periodicals to help support the struggling family, whose mainstay she continued all her life, her father's superiorities not being of the money-making order. But for many years afterward she groped for her true field, starting with sensational stories of no permanent merit. For ten years she was a school-teacher. In 1862 she went to Washington as a war hospital nurse, and wrote letters thence to her mother and sisters; on her return in 1863 she recast these into a volume entitled ‘Hospital Sketches,’ as the easiest available literary capital, not suspecting that she had found her kingdom. In these was first revealed her peculiar power of sketching commonplace people and scenes in all their commonplaceness, yet by the play of genial humor and rare selective art making them as charming as the best creations of the fancy. The success of these stimulated the publication of ‘Little Women’ (written 1867, after return from a year's European trip for impaired health, published 1868), which sold 60,000 copies the first year, and after 35 years remains one of the best copyrights in American literature. It raised her at once and justly to one of the front places in American authorship, and remains the one work of hers the world would much regret losing. In formal art it has no merits: there is no structure and no climax, merely detached scenes of an uneventful life; little delicacy of touch, though there are passages of much tenderness and pathos: but the healthy sense and stereoscopic lifelikeness make it rather an addition to people's actual experiences than their memories of fiction; and the girls, despite the blunt portrayal of surface faults and even over-harsh lack of idealization, are loved like sisters by millions. It is the world-photograph of the New England home and the American girl. This was her great opportunity: her own family and friends to « compose » and adorn, with scant need for imagination, of which she had little, or plot, in which she was very deficient. After this, with the necessity of inventing a set story, and her personal life mostly wrought into her previous work, her limitations were strongly apparent: ‘An Old-Fashioned Girl’ (1869), ‘Little Men’ (1871), and a series of later juveniles, though only less popular with the young than ‘Little Women,’ add nothing to her real reputation. They are also deformed by two unwholesome qualities: one derived from her father,— representing grown people mainly as vexatious interferences with children's enjoyment, and the latter as quite capable of teaching wisdom to their elders; the other a proof how much feminine craving lay underneath her spinster life,— making love-sentiment a sauce to everything from the kindergarten up, and the world one vast scene of « philandering.» But these pot-boilers had a higher motive and result than most money-earning, for they enabled her father to live his serene life. She adopted at different times a son of her sister, Mrs. John Pratt (« Meg ») and the orphaned daughter of her artist sister, Mme. Nieriken (« Amy ») ; and kept house for them and her father in vigorous New England fashion, caring for the latter like a baby. Fatigue and excitement during his last hours laid her low with a fatal brain fever. Besides the books above mentioned she published ‘Flower Fables or Fairy Tales’ (1855); ‘Moods’ (1864, revised 1881); a series, ‘Aunt Jo's Scrap Bag’ (1871–82); ‘Work, a Story of Experience’ (1873); ‘Eight Cousins’ (1874); ‘Rose in Bloom’ (1876); ‘Silver Pitchers’ (1876); ‘Under the Lilacs’ (1878); ‘Jack and Jill’ (1880); ‘Proverb Stories’ (1882); ‘Spinning-Wheel Stories’ (1884); ‘Lulu's Library’ (1885).

Alcott, May (Mme. Ernest Nieriken), American artist, daughter of A. B. Alcott: b. Concord, Mass., 1840; d. 1879. She studied at the Boston School of Design, and under Krug, Rimmer, Hunt, Vautier, Johnston, and Müller. Thenceforward she lived variously in Boston, London, and Paris; after marriage chiefly in the last. She did good work in still-life painting, both oil and water-color, and copied Turner so ably that Ruskin had some of the work adopted for models at the South Kensington schools. She published ‘Concord Sketches,’ with a preface by her sister (1869); ‘Art Studying Abroad’ (1879).

Alcoy, a town of Spain, in Valencia, 24 m. N. by W. of Alicante, near the source of the Alcoy, in a hollow encircled by hills. There is a Roman bridge over the river, and the town has

a very picturesque appearance. Its chief manufacture is paper, and it is likewise famed for sugar-plums. Pop. 32,000.

Alcuin, or **Flaccus Albinus,** an Englishman, renowned in his age for learning; the confidant, instructor, and adviser of Charlemagne. He was probably born in York in 735, and was educated under the care of Archbishop Egbert, and his successor Ælbert, with whom he went to the continent, and who afterward gave him the management of the school at York. Having gone to Rome to bring home the pallium (see PALLIUM) for Eanbert, the successor of Ælbert, Charlemagne became acquainted with him in Parma on his return; invited him, in 782, to his court, and made use of his services in his endeavors to civilize his subjects. In the royal academy he was called *Flaccus Albinus*. To secure the benefit of his instructions Charlemagne established at his court a school, called *Schola Palatina*, or the Palace School, and intrusted him with the superintendence of several monasteries, in which Alcuin exerted himself to diffuse a knowledge of the sciences. Most of the schools in France were either founded or improved by him; thus he founded the school in the abbey of St. Martin of Tours, in 796, after the plan of the school in York. He himself instructed a large number of scholars in this school, who afterward spread the light of learning through the empire of the Franks. Alcuin took his leave of the court in 801, and retired to the abbey of St. Martin of Tours, but kept up a constant correspondence with Charles to the time of his death in 804. He left, besides many theological writings, several elementary works in the branches of philosophy, rhetoric, and philology; also poems, and a large number of letters, the style of which, however, is not pleasing and plainly betrays the uncultivated character of the age; nevertheless he is acknowledged as the most learned and polished man of his time. He understood Latin, Greek, and Hebrew. The best edition of his works is that published at Ratisbon (1777, 2 vols. folio). See Lorenz's 'Life of Alcuin,' translated into English (London, 1837).

Alcyonaria (from Gk. *alkyon*[*e*]*ion*, bastard-sponge), a sub-class of coral polyps (*Anthozoa*), including fan-corals, «dead men's fingers,» organ-corals, the red coral used for beads and ornaments, and others. Eight tentacles around the mouth and the eight cells into which the body is divided are the characteristic elements of this group. See CORAL.

Alcyone, the brightest star of the Pleiades (q.v.). Also see KINGFISHER.

Al'dan, a river of E. Siberia, a tributary of the Lena, 1,200 m. in length, navigable for 600 m. The Aldan Mountains run along parallel to it on the left for 400 miles.

Aldana, Ramon, alda-na rä-mōn', Mexican poet: b. 1832; d. 1882. Besides four dramas, among which are 'Honor and Happiness' and 'Nobility of Heart,' he produced lyric poems and sonnets and contributed articles to journals.

Aldborough, or **Aldeburgh,** a small seaport and watering-place of Suffolk, 29 m. N.E. of Ipswich by rail. It was disfranchised in 1832; but in 1885 it received a new municipal charter. It has a quaint, half-timbered moot hall; and in the church is a bust of the poet Crabbe, who described the place in his poem, 'The Borough.' It has a two-mile promenade and lobster and herring fisheries. Pop. 2,150.

Aldeb'aran, a star of the first magnitude, forming the eye of the constellation Taurus or the Bull, the brightest of the five stars known to the Greeks as the Hyades. Spectrum analysis has shown it to contain antimony, bismuth, iron, mercury, hydrogen, sodium, calcium, etc.

Al'dehyde ("dehydrogenated alcohol," or alcohol which has been deprived of a portion of its hydrogen), a substance intermediate in composition between a primary alcohol and the corresponding acid. When an alcohol (q.v.) containing the molecular group $CH_2.OH$, is acted upon by oxidizing agents, it loses two atoms of hydrogen from this group, and becomes transformed into a substance which no longer contains the hydroxyl group (OH), and which is known as the «aldehyde» of the alcohol from which it was produced. Air effects the desired oxidization readily, when in the presence of platinum black. If the formula of the original alcohol is $R.CH_2.OH$, that of the corresponding aldehyde is R.CO.H. Aldehydes combine with bisulphites (or acid sulphites), producing compounds that are usually soluble in water, but insoluble in a solution of a bisulphite. Hence if a solution containing an aldehyde is shaken with a saturated solution of a bisulphite (such as $HNaSO_3$), the aldehyde is all thrown down in the form of an insoluble compound, from which the aldehyde itself may afterward be liberated by treatment with dilute sulphuric acid and distillation by steam. Aldehydes are easily oxidized into their corresponding acids, and on account of their affinity for oxygen they act as powerful reducing agents. An aldehyde may also be reconverted into the alcohol from which it was obtained, by the action of sodium amalgam. About 50 aldehydes are known, nearly all of which are volatile liquids.

The general relation of the aldehydes to their corresponding alcohols and acids may be illustrated by the following examples: The formula of methyl alcohol is $CH_3.OH$, or $H.CH_2.OH$. In the presence of platinum black, air oxidizes methyl alcohol in accordance with the following equation:

$$H.CH_2.OH + O = H_2O + H.CO.H.$$

H.CO.H (or CH_2O) is «formic aldehyde,» or «formaldehyde.» This rapidly absorbs oxygen and undergoes the change

$$\underset{\text{Formaldehyde}}{H.CO.H} + O = \underset{\text{Formic acid}}{H.COOH.}$$

Again, if ethyl alcohol ($C_2H_5.OH$, or $CH_3.CH_2.OH$) is treated in the same manner (or, better, if it is oxidized with a mixture of potassium bichromate and sulphuric acid), we have

$$\underset{\text{Ethyl alcohol}}{CH_3.CH_2.OH} + O = \underset{\text{Acetic aldehyde}}{CH_3.CO.H + H_2O.}$$

If allowed to absorb oxygen, acetic aldehyde then undergoes the further transformation

$$\underset{\text{Acetic aldehyde}}{CH_3.CO.H} + O = \underset{\text{Acetic acid}}{CH_3.COOH.}$$

Acetic aldehyde, or *acetaldehyde*.— When not qualified in any way aldehyde is understood to mean acetic aldehyde, the substance whose formation from ethyl alcohol has just

been described. Aldehyde (in this sense) is a colorless liquid with a suffocating smell, miscible in all proportions with water, alcohol, and ether, boiling at 70° F., and having a specific gravity of 0.800 at 32° F. It is capable of existing in several polymeric states, each having the same chemical composition as aldehyde, but differing from it in appearance and behavior. Thus although aldehyde may be preserved for a long time if kept in contact with excess of acid, in its pure state it soon deposits a solid substance known as metaldehyde, which sublimes at 250° F. without decomposition, and is reconverted into aldehyde when confined and heated to 400° F. By treatment with sulphuric or hydrochloric acid, aldehyde may be converted into a liquid known as paraldehyde, which boils at 255° F. and has a vapor density indicating the formula $3(C_2H_4O)$.

Aldehyde is used for silvering mirrors and other objects, on account of the property that it possesses (in common with other aldehydes) of throwing down a deposit of metallic silver when heated with a concentrated ammoniacal solution of silver nitrate containing a little caustic soda.

Alden, Bradford R., American soldier: b. Meadville, Pa., 1800; d. Newport, R. I., 10 Sept. 1870. Graduating at West Point 1831, he was instructor there 1833–40 after some camp and garrison life; then for nearly two years aide to Winfield Scott; after three years more of garrison duty was commandant at West Point 1845–52. Sent to the far West for service in the Puget Sound Indian troubles, in 1853 he organized and led an expedition against the Rogue River Indians of southwest Oregon; and in the fierce battle at Jacksonville 24 August, was permanently disabled and forced to retire from the army. He was a man of culture and fine literary tastes.

Alden, Henry Mills, American editor and author: b. Mt. Tabor, Vt., 11 Nov. 1836. He graduated 1857 at Williams College, in the class with Garfield and Horace E. Scudder; in 1860 at Andover Theological Seminary, and received license to preach, but was never ordained. He settled in New York in 1861; was managing editor of ‹ Harper's Weekly › 1863–9, and has been editor of ‹ Harper's Magazine › since 1869. His earliest interests were classical, especially in regard to ancient thought, religion, and literature: in the winter of 1863–4 he delivered 12 lectures at the Lowell Institute, Boston, on ‹ The Structure of Paganism ›; his earliest writings published were two papers on the Eleusinian Mysteries, in the ‹ Atlantic Monthly ›; and his classical scholarship is recognized as of a high type. In his editorial work he has sought to combine fresh intellectual outlook and the presentation of the latest results of scholarship with sound ethics and an elevating social tone; also to make the magazine American in the best sense and to bring forward new writers. He collaborated with A. H. Guernsey in ‹Harper's Pictorial History of the Great Rebellion› (1862–5); and has written ‹The Ancient Lady of Sorrow,› poem (1872); ‹God in His World› (1890, anonymous), and a ‹Study of Death› (1895), widely read and admired.

Alden, (Mrs.) **Isabella McDonald** («Pansy»), American juvenile writer: b. Rochester, N. Y., 3 Nov. 1841; married Rev. G. R. Alden 1866. She was educated at Ovid and Auburn, N. Y. While she has written fiction for adults, and ‹ The Prince of Peace,› a life of Christ, her chief note is as the author of the ‹ Pansy Books,› Sunday-school juvenile novels, about 60 volumes in all; and as editor of the juvenile periodical ‹ Pansy,› 1873–96. She has since been on the staff of the ‹ Christian Endeavor World › of Boston and the ‹ Herald and Presbyter › of Cincinnati. Her home is Philadelphia.

Alden, James, American naval officer: b. Portland, Me., 31 March 1819; d. San Francisco, Cal., 6 Feb. 1877. Becoming midshipman 1828, he accompanied the Wilkes expedition around the world 1838–42; commissioned lieutenant 1841, he served through the Mexican War in all the leading seaboard engagements. The Puget Sound Indian troubles called him thither 1855–6 for active duty. The Civil War found him in command of the steamer South Carolina, and he was sent to the Gulf and had a fight at Galveston, Tex.; later, in command of the sloop-of-war Richmond, he was at the passage of Forts Jackson and St. Philip and the capture of New Orleans and Port Hudson. He became captain 1863, and commanded the Brooklyn in the battle of Mobile Bay (August 1864) and the assaults on Fort Fisher; commodore 1866, and given charge of the Mare Island (Cal.) navy yard 1868; in 1869 made chief of the bureau of navigation, and in 1871 promoted to rear-admiral and assigned to command of the European squadron. He was retired 1873.

Alden, John, of the Plymouth colony: b. England, 1599; d. Duxbury, Mass., 12 Sept. 1687. His name is familiarized by Longfellow's poem ‹ The Courtship of Miles Standish.› He was originally a cooper of Southampton, was employed in making repairs on the Mayflower, and came over in her with the Pilgrim Fathers. By some accounts he was the first to step ashore at Plymouth. He married Priscilla Mullens: the tradition is (as used by Longfellow) that he had previously pleaded the cause of Miles Standish. He was for over 50 years a colonial magistrate, and highly esteemed for probity, sagacity, and resolution. All the distinguished Aldens of the United States are his descendants.

Alden, Timothy, inventor: b. Barnstable, Mass., 1819; d. December 1858. He was one of many thousands of printers who have dreamed of inventing type-setting machines, and of hundreds who have attempted it. He labored on one from 1846 till death, a horizontal rotating wheel with type-cells on its circumference, making receivers rotate with it to pick out the type at the proper places. His brother Henry W. improved the machine after his death.

Alden, William Livingston, American humorous writer and journalist: b. Williamstown, Mass., 9 Oct. 1837. He introduced the sport of canoeing into the United States. He was for a time United States consul-general at Rome. Among his principal writings are ‹ Domestic Explosives › (1877); ‹ Shooting Stars › (1878); ‹ The Canoe and the Flying Proa › (1878); ‹ Moral Pirates › (1880); ‹ The Comic Liar › (1882); ‹ Cruise of the Ghost › (1882); ‹ Life of Christopher Columbus › (1882); ‹ A New

Robinson Crusoe' (1888), etc. Since 1900 he has been London correspondent of the New York *Times*.

Aldenhoven, a town of Prussia, Rhine province; 12 m. N.E. of Aix-la-Chapelle. Here the French, in 1793, under Dumouriez, were defeated by 50,000 Austrians under Prince Josias of Coburg, and were prevented from making their contemplated invasion of Holland.

Alder, the common name for a genus of plants (*Alnus*), of the order *Cupuliferæ* (oak family). In the eastern United States it is a very common shrub, branching freely from the roots, and forming dense clumps along the banks of streams and in other wet places. On the west coast it often attains a height of from 40 to 60 feet in favorable locations. It is found in temperate and cold regions. The species familiar in England has a wood soft and light, but very durable in the water, and therefore well adapted to mill-work, sluices, piles of bridges, etc. Its bark and shoots are used for dye, and its branches for the charcoal employed in making gunpowder. The names black, red, and white-alder are often popularly applied to plants of other orders.

Alderman, Edward Sinclair, American clergyman and educator: b. Wilmington, N. C., 27 July 1861. He was graduated from Wake Forest College, N. C., in 1883 and the Southern Baptist Theological Seminary in 1886. He has held Baptist pastorates in Kentucky and has been president of Bethel College, Ky., from 1898.

Alderman, Edwin Anderson, American educator: b. Wilmington, N. C., 15 May 1861. He was educated at the University of North Carolina; was superintendent of the public schools of Goldsboro, N. C., 1884–87; assistant state superintendent of North Carolina, 1889–92; professor of English and history at the State Normal College, 1892–93; professor of the philosophy of education at the University of North Carolina, 1893–96; president of the latter institution, 1896–1900; president of Tulane University, 1900–1904, when he assumed the presidency of the University of Virginia. He has been active in educational work in the Southern States with the design of securing better schools and the increase of revenue from taxes for this purpose.

Alderman, a title pertaining to an office in the municipal corporations of Great Britain and the United States. In the United States the powers and duties of aldermen differ in the various States and cities. As a rule they are elected by popular vote and constitute the source of municipal legislation.

Alderman Lizard, or Chuckwalla, nicknames in California for a fat-bodied lizard (q.v.).

Al'derney (French Aurigny), an island belonging to Great Britain, on the coast of Normandy, 10 m. due W. of Cape La Hogue, and 60 from the nearest point of England, the most northerly of the Channel Islands. It is about 4 m. long and 1¼ broad, having an area of fully 3 sq. m. The coast is bold and rocky, the cliffs in many places rising from 100 to 200 feet in height. In the interior the soil is fertile, producing excellent crops of corn and potatoes. About a third of the island is occupied by grass lands; and the Alderney cows are famous for the richness of their milk. The climate is mild and healthy. The town of St. Anne is situated in a beautiful valley near the centre of the island. A judge, with six "jurats," chosen by the people for life, and 12 "douzaniers," representatives of the people, form a kind of local legislature; but the judge and jurats alone decide upon any measure, the douzaniers having only a deliberative voice. The French language still continues to prevail among the inhabitants, but all understand and many speak English. Alderney, Guernsey, Jersey, and Sark are the only parts of the Duchy of Normandy that have remained under the government of England since 1456. The Race of Alderney is a name given to the strait running between the coast of France and this island. Six miles northwest from Alderney are the Casquets, a cluster of rocks, on the largest of which is a lighthouse and a fog-bell. Pop. (1901) 2,062.

Aldershot, Camp at, a permanent camp for the army in England, commenced in 1854 by the purchase, on the part of government, of an extensive tract of moorland known by the name of Aldershot Heath, lying on the confines of Surrey, Hampshire, and Berkshire. The object was to accustom the officers and soldiers to act in brigades and divisions, and to familiarize them with the operations of a campaign by accustoming them to camp life, and exercising them in all the evolutions which they might be required to perform when brought into actual contact with the enemy. The Basingstoke Canal divides the camp into a North and a South Camp (otherwise known respectively as Marlborough and Stanhope Lines). The accommodation provided for the army consisted at first of wooden huts of the simplest construction; but these have been superseded by brick buildings, and altogether the money expended on the camp has amounted to upward of $20,000,000.

A town has sprung up in the neighborhood of the camp, immediately beyond the government ground, on the edge of which the camp is established. The town of Aldershot is in Hampshire, to the south of the barracks. It contains several churches, hotels, numerous shops, and offers accommodation of various kinds, good and bad, to the soldiers: thus there are schools, newspapers, missions, literary institutes, music-halls, public-houses, etc. Pop. (1901) 30,974 (including military).

Ald'helm, an Anglo-Saxon scholar and prelate, bishop of Sherborne: b. 640 (?); d. 709. He was a great fosterer of learning and builder of churches, and has left Latin writings on theological subjects.

Aldine Editions, the books printed by Aldus Manutius and his family in Venice (1490–1597). They comprise the first editions of Greek and Roman classics; others contain corrected texts of modern classic writers, as of Petrarch, Dante, or Boccaccio, carefully collated with the MSS. All of them are distinguished for the remarkable correctness of the typography; the Greek works, however, being in this respect somewhat inferior to the Latin and Italian. The editions published by Aldo Manuzio (1450–1515), the father, form an epoch in the annals of printing, as they contributed in no ordinary measure to the perfecting of types.

EDWIN ANDERSON ALDERMAN

PRESIDENT OF UNIVERSITY OF VIRGINIA

ALDER.

1. Tip of Twig with Budding Catkins (Alnus glutinosa).
2. Male Flowers.
3. A Single Flower, showing Anthers.
4. Female Flowers.
5. Stamens of Female Flower.
6. Fruit
7. Fruit Case.
8. Empty Fruit Case.
9. Twig, with Three Buds
10. Spray, with Fruit (Alnus incana).

No one had ever before used such beautiful Greek types, of which he got nine different kinds made, and of Latin as many as 14. It is to him, or rather to the engraver, Francesco of Bologna, that we owe the types called by the Italians *Corsivi*, and known to us as italics, which he used for the first time in the octavo edition of ancient and modern classics, commencing with Virgil (1501). Manuzio's impressions on parchment are exceedingly beautiful; he was the first printer who introduced the custom of taking some impressions on finer or stronger paper than the rest of the edition — the first example of this being afforded in the ‹ Epistolæ Græcæ › (1499). From 1515 to 1533 the business was carried on by his father and brothers-in-law, Andrea Torresano of Asola, and his two sons — the three Asolani. Paolo Manuzio (1512–74), Aldo's son, possessed an enthusiasm for Latin classics equal to that of his father for Greek; and he was succeeded by his son, the younger Aldo (1547–97). The printing establishment founded by Aldo continued in active operation for 100 years, and during this time printed 908 different works. The distinguishing mark is an anchor, entwined by a dolphin, with the motto either of « *Festina lente* » or of « *Sudavit et alsit.* » The demand which arose for editions from this office, and especially for the earlier ones, induced the printers of Lyons and Florence, about 1502, to begin the system of issuing counterfeit Aldines. The Aldo-mania has considerably diminished in later times. Among the Aldine works which have now become very rare may be mentioned the ‹ Horæ Beatæ Mariæ Virginis › of 1497, the ‹ Virgil › of 1501, and the ‹ Rhetores Græci, › not to mention all the editions, dated and undated, from 1490 to 1497, which are now extremely rare. See Renouard's ‹ Annales de l'Imprimerie des Aldes › (1834), and Didot's ‹ Alde Manuce › (1873).

Aldobrandi'ni, the name of a Florentine family, latterly of princely rank (now extinct), which produced one Pope (Clement VIII.) and several cardinals, archbishops, bishops, and men of learning.

Aldobrandini Marriage, an ancient fresco painting belonging probably to the time of Augustus, discovered in 1606, and acquired by Cardinal Aldobrandini, nephew of Clement VIII., now in the Vatican. It represents a marriage scene in which 10 persons are portrayed, and is considered one of the most precious relics of ancient art.

Al'dred, or **Ealdred,** Anglo-Saxon prelate, bishop of Worcester and archbishop of York: b. 1000 (?); d. 1069. He improved the discipline of the Church and built several ecclesiastical edifices. On the death of Edward the Confessor he is said to have crowned Harold. Having submitted to the Conqueror, whose esteem he enjoyed and whose power he made subservient to the views of the Church, he also crowned him as well as Matilda.

Aldrich, Anne Reeve, American poet and novelist: b. New York, 25 April 1866; d. there, 22 June 1892. She wrote ‹ The Rose of Flame › (1889); ‹ The Feet of Love, › novel (1890); ‹ Songs about Life, Love, and Death › (posthumous, 1892). Her early death was widely regretted from the brilliant promise of her work, especially in poetry: some of her lyrics of passion and regret are among the most perfect of American poetic gems in symmetrical art.

Ald'rich, Henry, dean of Christchurch, Oxford: b. 1647; d. 1710. He was distinguished as a writer on logic, as an architect, and as a musician. His ‹ Compendium of Logic › was a text-book till quite recently. He adapted many of the works of the older musicians, such as Palestrina and Carissimi.

Aldrich, James, American poet: b. Mattituck, L. I., 14 July 1810; d. New York, 9 Sept. 1856. His best known poem is ‹ The Death-Bed, › an imitation of Hood, preserved in most anthologies.

Aldrich, Nelson Wilmarth, American legislator: b. Foster, R. I., 6 Nov. 1841. A farmer's lad, with district-school education, he was clerk in a store from about 12 to 16; but, naturally studious and with a strong taste for mathematics, entered the East Greenwich Academy in 1857, and after graduation took a position in a large wholesale house in Providence, where he soon became a partner. In 1862 he was for nine months on garrison duty near Washington. In 1869 he was elected to the Providence Common Council, where he became a leader as expert in finance and business, and a dextrous manager without compromise of right, and was its president 1871–3. In 1875 he was elected to the legislature, and in 1876 was Speaker of its House. In 1878 he was sent to Congress, taking his seat in 1879 (Forty-second Congress); re-elected for the term 1881–3, he resigned in 1881, having been elected to the United States Senate on the 4th of October, to succeed Gen. Burnside, and has been three times re-elected,— in 1886, 1892, and 1898, practically without opposition in his party. During more than 20 years he has been known as one of the chief Republican leaders, an authority on finance and political economy, and a champion of protection; rarely taking part in debate, but powerful in legislative work, a member of committees on civil service and finance, and chairman of the committee on rules for the Fifty-fifth Congress. He was president of the Providence Board of Trade in 1878.

Aldrich, Thomas Bailey, author: b. Portsmouth, N. H., 11 Nov. 1836. Prepared for Harvard, but his father's death (1852) prevented a college career. Held editorial positions on the New York *Evening Mirror* and N. P. Willis' ‹Home Journal› till 1865. Edited ‹Every Saturday,› Boston, 1865–74, and ‹ The Atlantic Monthly, › 1881–90. As a poet he combines conciseness and aptness of expression with a faculty for bringing into conjunction subtly contrasted thoughts, images, or feelings. The best of his short stories are surpassed by no other American writer. In prose and verse he has ever held himself to the highest ideals of literary art and workmanship. His best known volumes are, in verse, ‹Cloth of Gold› (1874); ‹ Lyrics and Sonnets › (1880); ‹ Friar Jerome's Beautiful Book› (1881); ‹Ballad of Baby Bell › (1856); ‹ Wyndham Towers › (1890); ‹ Unguarded Gates and Other Poems › (1895); ‹ Mercedes, a Drama › (1883); in prose, ‹ Story of a Bad Boy › (1870); ‹ Marjorie Daw and Other People › (1873); ‹ Two Bites at a Cherry, and Other Tales › (1893); ‹ A Sea Turn › (1902).

Aldridge, Ira Frederick, American negro tragedian: b. (?); d. Lodz, Poland, 7 Aug. 1867. The discrepancies about his birth and training are monstrous, and indicate invention on one side. One is that he was a mulatto, born near Baltimore about 1810, who picked up German from immigrants, became Edmund Kean's servant, and developed stage talent under him in England, returned and made a theatrical failure in Baltimore 1830–1, then went back to England and became famous. The other is that he was son of a full-blooded negro pastor in New York city (Greene Street Chapel), an immigrant Senegal chieftain converted and educated, who sent his son to Glasgow University to study for the same profession, despite a passion for the stage justified by successful amateur performances; but the boy (at this point the stories coincide) dropped theology and made his début at the Royal Theatre as Othello. He took at once; and Kean made him Othello to his Iago in Belfast. He played Shakespearean roles in London till 1852, regarded as an excellent interpreter in all, but most liked in color-parts, such as Othello, Aaron in 'Titus Andronicus,' Rolla, Zanga, etc. He then played in Brussels and Germany 1852–5; the king of Sweden invited him to Stockholm in 1857. The Continent ranked him one of the foremost actors of the age, and the greatest sovereigns, with cities like Bern, showered honors and decorations on him and made him member of all sorts of learned societies. He married an Englishwoman. He was on his way to an engagement in St. Petersburg when he died.

Aldrovandi, Ulisse, Italian naturalist: b. Bologna, 11 Sept. 1522; d. 10 May 1605. He aroused interest in the natural sciences at a time when they had been long neglected, wrote profusely on natural history subjects, established the Botanical Garden of Bologna, and, through his legacy to the Senate of Bologna of his collections, left behind him the germ of the great Bologna Museum. A short account of his life, together with a descriptive list of his published writings and manuscripts, may be found in 'Notizie degli Scrittori Bolognesi,' Vol. I. (Bologna 1781). He was the first to collect an herbarium, in the modern sense of the word. He traveled widely, collecting plants and animals, and preparing himself to write a great work on the animal life of the world. Of this work four volumes on ornithology and one on mollusks were issued before his death, and 10 others, prepared by him from his material, were brought out afterward by his pupils and friends. Many of his manuscripts and drawings were preserved unpublished in the library of Bologna.

Ale and Beer, well known and extensively used fermented liquors, the best of which is prepared from barley after it has undergone the process termed malting. Beer is a more general term than ale, being often used for any kind of fermented malt liquor, including porter, though it is also used in a more special signification. "The numerous varieties of malt liquors met with in commerce may be resolved into three great classes — ale, beer, porter. Ale, as the term is generally understood, is a pale liquor brewed from lightly-dried malt, and abounding more or less in undecomposed saccharine matter and mucilage and the bitter and fragrant principles of the hop; characteristics which, however, it more or less loses by maturation and age. Beer is a fine, strong, well-fermented liquor, darker, less saccharine, and more alcoholic than ordinary ale. Porter is a dark-brown colored liquor, originally brewed from high-dried malt, but now generally made from pale malt, with a sufficient quantity of patent or roasted malt to impart the necessary color and flavor. Stout, brown stout, etc., are mere varieties of porter, differing from that liquor only in their superior strength and quality. East India ale, bitter ale, etc., of the great brewers, are beverages which combine the pale color and fragrant bitter of ale (the latter usually in undue excess) with the 'dryness' and maturity of beer. Table-ale or table-beer is a weak liquor, commonly containing three or four times the proportion of water usually present in ordinary beer or ale. In London porter is called beer, and indeed in all parts of the kingdom the prevailing beverage of this kind consumed by the masses, of whatever class, commonly goes by the name of beer. The three great classes of malt liquor above referred to are, independent of mere differences of strength, excellence, and commercial value, practically subdivided into an almost infinite number of varieties. Every county, every town, and almost every brewer is distinguished by the production of a different flavored beer, readily perceived and highly appreciated by their respective votaries" (Cyclopædia of Practical Receipts). These differences depend chiefly on the quality of the materials and the varying proportions in which they are employed, the temperature of the water used for mashing, the length of time the mash is boiled, the temperature at which fermentation is effected, and the extent to which it is allowed to proceed. The color of the beer depends on the color of the malt and the length of time occupied by the boiling. The pale ale is made from malt dried by steam or in the sun; the deep-yellow ale, from a mixture of pale, yellow, and brown malt; and the dark-brown beer from malt that has been highly dried in the kiln and partly carbonized, mixed with the paler sorts. Besides being made from barley, maize, wheat, and other grains, beer may be manufactured from a good many other amylaceous and saccharine substances, such as beet-root, potatoes, turnips, beans, cane-syrup, molasses, etc., but the best is that made from barley-malt. Some of these substances are extensively employed in Germany, which has been celebrated as a beer-drinking country from the earliest times. Many different kinds of beer are there made, among the most important being the Bavarian summer or lager (that is, store) beer, and winter beer, the Bavarian bock beer, Berlin white beer, wheat lager beer, Broyhan beer (Hanover), Merseburg brown beer, etc. The Bavarian beer possesses excellent qualities, and is distinguished from most of the beers of Germany and other countries by the valuable property of not turning sour on exposure to the air, so that it can be preserved in half-full casks equally well as in full ones. This quality it owes to the way in which it is fermented, this being done by the *untergährung* process, or process of fermentation from below. The malt-wort is set to ferment in open backs

with an extensive surface and placed in cold cellars with a temperature not higher than 46½° to 50°. The operation lasts three or four weeks, and the wort, instead of showing a large head of froth, is scarcely covered with any, the yeast sinking to the bottom in the form of a viscid sediment called the *unterhefe*, or bottom-yeast. This bottom-yeast is a different substance from the precipitate which falls to the bottom of the backs in the ordinary fermentation of beer. The summer or lager beer is brewed in the coldest months of the year, namely December, January, and February, and is stored up in air-tight cellars. The winter beer is intended for almost immediate consumption, and is hence called *schenk* (that is, pot or draught) beer. It is rather weaker than the summer beer. The Bavarian bock beer is a double-strength beverage of the best lager description, with a somewhat darker color than the ordinary lager beer and a sweeter taste. Berlin white or pale beer (*weissbier*) is brewed from one part of barley malt and five parts of wheat malt.

The manufacture of ale or beer is of very high antiquity. Herodotus ascribes the invention of brewing to Isis, and tells us that the Egyptians drank a liquor which they called *zuthos*, fermented from barley. Ale or beer was never used to a great extent in Greece or Italy, partly owing, no doubt, to the abundance of wine in these countries. Xenophon, in his 'Anabasis,' mentions it as being used among the inhabitants of Armenia, and the Gauls were also acquainted with it in early times. Ale or beer was in common use in Germany in the time of Tacitus. "All the nations," says Pliny, "who inhabit the west of Europe have a liquor with which they intoxicate themselves, made of corn and water (*fruge madida*). The manner of making this liquor is somewhat different in Gaul, Spain, and other countries, and it is called by many various names; but its nature and properties are everywhere the same. The people of Spain, in particular, brew this liquor so well that it will keep good for a long time. So exquisite is the ingenuity of mankind in gratifying their vicious appetites that they have thus invented a method to make water itself intoxicate." Our Teutonic ancestors would of course bring with them from the Continent their national beverage, and accordingly we find ale mentioned in English history in very early times. It is mentioned in the laws of Ina, king of Wessex (680), and ale-booths were regulated by law in 728. It was customary in the reigns of the Norman princes to regulate the price of ale, and a statute passed in 1272 enacted that a brewer should be allowed to sell two gallons of ale for a penny in cities, and three or four gallons for the same price in the country. The use of hops in the manufacture of ale and beer seems to have been a German invention, and the name beer appears to have come from Germany to England with this practice (1524), after which "beer" and "ale" were used respectively for the hopped and the unhopped liquor. In 1552 hop plantations had begun to be formed in England. Ale-houses were first licensed in 1621, and in Charles II.'s reign duties amounting to 2*s*. 6*d*. a barrel on strong, and to 6*d*. on small ale or beer, were imposed for the first time (1660). From that time up to 1830, when it was entirely repealed, though the malt-tax remained, the duty on the barrel of strong beer varied, being in 1804 as high as 10*s*. Up to 1823 beer was classed into strong beer and small beer, the former being beer of the value of 16*s*. and upward the barrel, the latter beer below this value. See also BREWING.

Alemanni. See ALAMANNI.

Aleardi, Gaetano, Italian poet and patriot: b. Verona 4 Nov. 1812; d. there 17 July 1878. From his boyhood he was devoted to the study of political and social questions, and was so active in the insurrection in Venetia (1848–9) that he was twice imprisoned by the Austrians. As a poet he has always been popular in Italy, and many editions of his works have been published.

Alembert, Jean le Rond d', a French mathematician and philosopher: b. Paris 16 Nov. 1717; d. there 29 Oct. 1783. The illegitimate child of Chevalier Destouches-Canon and the celebrated Madame de Tencin, sister of the archbishop of Lyons, he was abandoned in infancy near the church of St. Jean de Rond, a fact from which his Christian name was derived. After he had attained eminence his father recognized him and gave him a pension. While still very young he displayed such precocity of talent that he was placed in the College Mazarin, where he became deeply interested in mathematics and philosophy, and, in fact, while he attempted to study both medicine and law, his inability to turn his mind to either of these professions determined him to become a mathematician. In 1740, he was admitted to membership in the Academy of Sciences, and, a year later, he published his celebrated 'Treatise on Dynamics.' Other scientific work followed rapidly, and in 1750 he became associated with Diderot in the publication of the 'Encyclopedia,' for which he wrote the introduction, the article on mathematics, and many of the biographies. In 1754 he became a member of the French Academy, and in 1772, having declined several pressing invitations to become royal tutor at the court of Russia, he was elected perpetual secretary of the Academy. His 'Elements of Philosophy,' in which he followed the principles of Locke to their ultimate conclusion, both in skepticism and materialism, had appeared in 1759. Two editions of his works have been published: Paris, 1805, 18 vols. 8vo., and Paris, 1821, 5 vols. 8vo.

Alencar, Jose Martiniano de, celebrated Brazilian jurist and novelist: b. Ceara 1 May 1829; d. Rio de Janeiro 12 Dec. 1877. Although prominent in his profession he is best known as a writer of fiction, his most popular works being 'O Sertanejo,' 'Iracema,' and 'O Guarany,' all of which are stories of local Indian and colonial life.

Alessandria, Armistice of, the armistice under which the Austrian general, Melas, retired after the celebrated battle of Marengo, 16 June 1800. By this act Gen. Melas abandoned to Napoleon every fortification in northern Italy west of the Mincio, a result which, according to the opinions of the historians, was a more serious blow to the Austrian cause than an unconditional surrender would have been.

Alesund, a town on the western coast of Norway. Its chief industry is codfishing. Pop. about 12,000.

Aletia. See COTTON INSECT PESTS.

Aleurone, a substance rich in nitrogen, found in the cells of seeds. In the legumes it is found imbedded in the grains of starch, but in grains it constitutes the inner nodule. It is sometimes called gluten (q.v.).

Aleu'tian Islands, a chain of about 80 small islands belonging to Alaska Territory, separating the sea of Kamchatka from the northern part of the Pacific Ocean and extending nearly 1,600 miles from east to west between lon. 172° E. and 163° W.; total area, 6,391 sq. m. Pop. (1900), about 2,500. They are of volcanic formation, and in a number of them there are volcanoes still in activity. Their general appearance is dismal and barren, yet grassy valleys capable of supporting cattle throughout the year are met with, and potatoes, turnips, and other vegetables are successfully cultivated. They afford also an abundance of valuable fur and of fish. The natives belong to the same stock with those of Kamchatka. They are a strong hardy race, capable of enduring extremes of heat and cold. They are nominally Christianized, and are connected with the Greek Church of Russia. See ALASKA.

Alewife (possibly from *aloofe,* its Indian name), a small anadromous fish (*Pomolobus pseudoharengus*) found abundantly along the east coast of the United States, except at the extreme north and south. Somewhat earlier in the spring than its relatives, it goes up the rivers in multitudes to spawn. The eggs, which are voided in vast quantities, sink to the bottom and stick to rocks, etc. It is closely allied to both the herring and the shad, but it most resembles the shad in shape and color, though it is only from 8 to 10 inches long. It is less esteemed for its quality than the shad, but is of great importance as a food fish, and is taken by millions annually. This fish is called « gaspereau » in St. Lawrence Bay, and « branch herring » and « sawbelly » locally elsewhere; but the « alewife » of Bermuda is an entirely different fish, the round pompano.

Alexander, a name of various ancient writers, philosophers, etc. (1) ALEXANDER of Ægæ; a peripatetic philosopher of the 1st century A.D.; tutor of Nero. (2) ALEXANDER the Ætolian; a Greek poet who lived at Alexandria about 285–247 B.C., reckoned as one of the seven poets constituting the tragic pleiad. (3) ALEXANDER of Aphrodisias, surnamed Exegetes; lived about 200 A.D.; a learned commentator on the works of Aristotle. (4) ALEXANDER CORNELIUS, surnamed Polyhistor, of the 1st century B.C. He was made prisoner during the war of Sulla in Greece and sold as a slave to Cornelius Lentulus, who took him to Rome, made him the teacher of his children, and restored him to freedom. The surname Polyhistor was given him on account of his prodigious learning. The most important of his voluminous works was one in 42 books, containing historical and geographical accounts of nearly all the countries in the ancient world. (5) A Greek rhetorician and poet, surnamed Lychnus; lived about 30 B.C., wrote astronomical and geographical poems. (6) ALEXANDER NUMENIUS; a Greek rhetorician and teacher of elocution, of the 2d century A.D., two of whose works are historically known. (7) ALEXANDER the Paphlagonian; a celebrated impostor who lived about the beginning of the 2d century A.D., obtained a great influence with the people as an oracle; pretended to be Æsculapius reappeared. Lucian chiefly has made him known to us. (8) A Greek rhetorician of the 2d century A.D., surnamed Peloplaton, who vanquished Herodes Atticus in a rhetorical contest. (9) ALEXANDER PHILALETHES; a physician of the 1st century B.C., who succeeded Zeuxis as president of the famous Herophilean school of medicine. (10) SAINT ALEXANDER (d. 326 A.D.); the Patriarch of Alexandria from 312 A.D.; an opponent of Arius; member of the Council of Nice (325 A.D.); commemorated in the calendar 26 February. (11) ALEXANDER of Tralles; an eminent physician of Lydia, of the 6th century A.D.; author of two extant Greek works.

Alexander, the name of eight Popes.

1. ALEXANDER I., bishop of Rome about 109 A.D., recorded on the list of Popes by all the chronicles except Optatus Milevitanus. He confirmed, some say introduced, the rite of using unleavened bread for the Eucharist, of blessing water with salt, and certain rubrics in the mass. He died a martyr's death.

2. ALEXANDER II., Anselmo Baggio, a native of Milan; he lived for some time at the court of Henry III., and in 1056 or 1057 became Bishop of Lucca. In 1059 he became papal legate at Milan, and, 1 Oct. 1061, through the zeal of Hildebrand, he was raised to the papal throne, consequently the imperial party elected Bishop Cadaloüs of Parma, a rival Pope, as Honorius II. Alexander was driven by him in 1062 from the vicinity of Rome. He then withdrew to Lucca, and on the decision of the contest by Bishop Burchard of Halberstadt he was sent by the German court to Italy and recognized as Pope. At the Council of Mantua in 1604, with the assistance of Anno of Cologne, he got possession of Rome against his rival. His reign, under the influence of Hildebrand, carried out the reform of the churches and their emancipation from secular control. When Henry IV. wished a divorce from his wife Bertha, Alexander, through his legate, Cardinal Pietros Damiana, decided against him and summoned the king to Rome to answer for his crimes, but shortly after he died, 21 April 1073.

3. ALEXANDER III. (d. 1181), Rolando Ranuci; Pope, 1159–81. His career is historically important because of his vigorous prosecution, in opposition to Frederick Barbarossa, of the policies begun by Hildebrand. Three anti-Popes, Victor IV., Pascal III., and Calixtus III., had been confirmed in succession by the emperor. Alexander succeeded, and after the decisive victory at Legnano compelled Frederick's submission. The papal struggle was carried on in England by Thomas à Becket, ending in a victory for Alexander. William the Lion, of Scotland, was excommunicated for opposing him. Important decrees were issued by Alexander III., safeguarding ecclesiastical powers and privileges.

4. ALEXANDER IV., Pope 1254–61; a man of great gifts, which, however, were of little avail in his unfortunate times. His administration is

signalized by attempts to unite the Greek and Roman Churches, and the establishment of the Inquisition in France (1255). He was the nephew of Gregory IX. In his battle with Manfred of Sicily, he suffered bitter humiliations and, deserted by his bishops, was obliged to escape from Rome. He died in Viterbo in 1261.

5. ALEXANDER V., Pietro Philargi, of Candia. He was for some time professor in Paris, and in 1402 was made Archbishop of Milan, and in 1404 cardinal. In 1409, after the deposition of the rival Popes, Gregory XII. and Benedict XIII., he was elected Pope by the cardinals at the Council of Pisa, but was recognized by only a part of Christendom. He forbade the teaching of Wyclif in Bohemia, and prohibited Huss from preaching even in private chapels. He died at the age of 70, and it was supposed by some, though without foundation, that he was poisoned by his successor, Balthasar Cossa (Pope John XXIII.).

6. ALEXANDER VI., Roderick Llançol, was born at Cativa, in the diocese of Valencia, in Spain, 1 Jan. 1431. He assumed the name Borgia when his uncle of that name became Pope as Calixtus III. After studying law he entered the papal court and was advanced rapidly, becoming commendatory archbishop of Valencia, cardinal deacon, and vice-chancellor of the Church in Rome. Appointed cardinal-bishop of Albano in 1476, he was ordained priest in that year. By the unanimous consent of the cardinal electors he was crowned Pope 11 Aug. 1492. His administration was a remarkable one. He cleared Rome of the bandits who had infested the city; held court every Wednesday; established the Congregation of the Index for the censorship of books; repressed the insolence and rapacity of the Roman nobility; put a stop to the falsification of ecclesiastical documents; drew up measures for the reformation of ecclesiastical discipline; cooperated with European rulers in their projects against the inroads of the Saracens; effected peace between the kings of Spain and Portugal by repartitioning between them their discoveries in the New World; provided missionaries for preaching the gospel in newly explored countries; approved and confirmed several religious congregations; restored discipline in the Church in Flanders; suppressed magic in Germany and Bohemia; popularized the custom introduced by Calixtus III. of saying the Angelus at midday; encouraged arts, particularly painting and literature; put an end to the famines which had so often visited Rome; and issued many noted bulls, letters, and other papal documents, which alone show that he was a man of extraordinary genius and power.

He is charged by historians like Guicciardini and Burchard and more modern writers who follow them, of licentiousness before his ordination to the priesthood, of simony, nepotism, and cruelty as Pope. It is difficult to reconcile all the crimes attributed to him with his high qualities and distinguished deeds. Of late years the tendency of moderate historians is to exonerate him from many extreme charges, to extenuate the faults of his youth, and cast doubt on the serious accusations brought against him as Pope.

7. ALEXANDER VII., Fabio Chigi, of Siena, was during the treaties of peace at Münster and Osnabrück, papal nuncio in Germany. He was chosen Pope 7 April 1665, through the influence of France. In 1161, in spite of the protests of the Jansenists, he confirmed the condemnation of the five Jansenist dogmas which had been condemned by his predecessor, Innocent X. Later he fell into controversy with Louis XIV. During his rule Rome was beautified in many directions, especially by the colonnade before St. Peter's. He was himself a poet and friend of the arts and sciences. A collection of his poems appeared in 1656.

8. ALEXANDER VIII. (1610–91), Pietro Ottoboni, of Venice; Pope 1689–91; assisted Italy in wars against the Turks. Through the purchase of the library of Queen Christina of Sweden he enriched the Vatican with 1,900 precious manuscripts. The collection is known as the Ottobonian Library.

Cambridge 'Modern History,' Vol. I.; Hefele, 'History of the Councils'; Parsons, 'Studies in Church History'; Pastor, 'History of the Popes.'

Alexander I., emperor of Russia, son of Paul I. and Maria, daughter of Prince Eugene of Würtemberg: b. 23 Dec. 1777; d. 1 Dec. 1825. On the assassination of his father, 24 March 1801, Alexander ascended the throne, and soon after a ukase was published for diminishing the taxes, liberating debtors, etc. One of the first acts of his reign was to conclude peace with Great Britain, against which his predecessor had declared war. In 1803 he offered his services as mediator between England and France, and two years later a convention was entered into between Russia, England, Austria and Sweden for the purpose of resisting the encroachments of France on the territories of independent states. He was present at the battle of Austerlitz (2 Dec. 1805), when the combined armies of Russia and Austria were defeated by Napoleon. Alexander was compelled to retreat to his dominions at the head of the remains of his army. In the succeeding campaign the Russians were again beaten at Eylau (8 Feb. 1807), and Friedland (14 June), the result of which was an interview a few days after the battle, on a raft anchored in the Niemen, between Alexander and Napoleon, which led to the treaty signed at Tilsit, 7 July. The Russian emperor now for a time identified himself with the Napoleonic schemes. The seizure of the Danish fleet by the British brought about a declaration of war by Russia against Great Britain and Sweden, and Alexander invaded Finland and conquered that long-coveted duchy, which was secured to him by the peace of Friedrichshamn (1809). In 1809–12 war was carried on against Turkey. The French alliance, however, he found to be too oppressive, and his having separated himself from Napoleon led to the French invasion of 1812. In 1813 he published the famous manifesto which served as the basis of the coalition of the other European powers against France. After the battle of Waterloo, Alexander, accompanied by the emperor of Austria and the king of Prussia, made his second entrance into Paris, where they concluded (26 Sept. 1815), the treaty known as the Holy Alliance. The remaining part of his reign was chiefly taken up in measures of internal reform, including the

gradual abolition of serfdom, and the promotion of education, agriculture, commerce, and manufactures.

Alexander II., emperor of Russia: b. 29 April 1818; succeeded his father Nicholas in 1855, before the end of the Crimean war. After peace was concluded the new emperor set about effecting reforms in the empire, among the first being the putting of the finances in order. The greatest of all the reforms carried out by him was the emancipation of the serfs by a decree of 2 March 1861. The czar also did much to improve education in the empire and introduced a reorganization of the judicial system. During his reign the Russian dominions in central Asia were considerably extended, while to the European portion of the monarchy was added a piece of territory south of the Caucasus, formerly belonging to Turkey in Asia. A part of Bessarabia, belonging since the Crimean war to Turkey in Europe, but previously to Russia, was also restored to the latter power. The latter additions resulted from the Russo-Turkish war of 1877-8, in which the Turks were completely defeated, the Russian troops advancing almost to the gates of Constantinople. Toward the end of the czar's life several attempts at his assassination were made by Nihilists, and at last he was killed by an explosive missile flung at him in a street in St. Petersburg, 13 March 1881. He was succeeded by his son, Alexander III.

Alexander III., emperor of Russia, son of Alexander II.; b. 10 March 1845; d. Livadia, 1 Nov. 1894. He married the daughter of the king of Denmark in 1866. After his father's death, through fear of assassination, he shut himself up in his palace at Gatschina. His coronation was postponed till 1883, and was celebrated with extraordinary magnificence, and with national festivities lasting several days. Through the fall of Merv, the subjugation of the Turkomans in central Asia was completed. In 1885 hostilities with England with regard to the defining of the frontier between the Russian territories and Afghanistan for a time seemed imminent. In European affairs he broke away from the triple alliance between Russia, Germany, and Austria, and looked rather to France. He was aggrieved by the new Bulgarian spirit. His home policy was reactionary, though strong efforts were made to prevent malversation by officials, and stern economics were practised. The liberties of the Baltic provinces and of Finland were curtailed, the Jews were oppressed, and old Russian orthodoxy was favored. Several Nihilist attempts were made on his life, and throughout his reign he kept himself practically a prisoner in his palace.

Alexander I., king of Scotland, fourth son of Malcolm Canmore; b. about 1078, in 1107 succeeded his brother, Edgar, only, however, to that part of the kingdom north of the firths of Forth and Clyde; d. Stirling, 1224. He married Sibylla, a natural daughter of Henry I. of England, and his reign was comparatively untroubled, though about 1115 he had to quell an insurrection of the northern clans. He founded the abbeys of Scone and Inchcolm and initiated a diocesan episcopate; while his determined resistance to the claims of York and Canterbury to supremacy over the see of St. Andrews did much to secure the independence, not only of the Scottish Church, but of Scotland itself.

Alexander II., king of Scotland: b. Haddington, 1198; d. 1249. He succeeded his father, William the Lion, in 1214. He early displayed that wisdom and strength of character in virtue of which he holds so high a place in history among Scottish kings. His entering into a league with the English barons against King John drew down upon him and his kingdom the papal excommunication; but two years later the ban was removed, and the liberties of the Scottish Church were even confirmed. On Henry III.'s accession to the English throne, Alexander brought the feuds of the two nations to a temporary close by a treaty of peace (1217), in accordance with which he married Henry's eldest sister, the Princess Joan (1221). The alliance thus established was broken after her death without issue (1238) and the second marriage of Alexander with the daughter of a noble of France. In 1244 Henry marched against Scotland to compel Alexander's homage; but a peace was concluded without an appeal to arms. In 1249, while engaged in an expedition to wrest the Hebrides from Norway, Alexander died of fever on Kerrera, near Oban.

Alexander III., king of Scotland: b. 1241; succeeded his father, Alexander II., 1249; d. 12 March 1286. In 1251 he married the Princess Margaret (1240-75), eldest daughter of Henry III. of England. Very shortly after he had come of age his energies were summoned to defend his kingdom against the formidable invasion of Haco, king of Norway (1263), whose utter rout at Largs secured to Alexander the allegiance both of the Hebrides and the Isle of Man. The alliance between Scotland and Norway was strengthened in 1282 by King Eric's marriage to Alexander's only daughter, Margaret (1261-83); the untimely death of their infant daughter, Margaret, commonly designated the Maid of Norway, on her way to take possession of her throne, was the occasion of many calamities to Scotland. During the concluding years of Alexander's reign the kingdom enjoyed a peace and prosperity which it did not taste again for many generations. His only surviving son died without issue in 1284; and next year Alexander contracted a second marriage with Joleta, daughter of the Count de Dreux.

Alexander I., king of Servia: b. 14 Aug. 1876; son of King Milan I. In 1889 Milan abdicated and proclaimed Alexander king under a regency till he should attain his majority (18 years). On 13 April 1893, when in his 17th year, Alexander suddenly took the royal authority into his own hands and summarily dismissed the regent. On 5 Aug. 1900 he married Mme. Draga Maschin. This marriage was exceedingly unpopular by reason of the character of the new queen, and this fact, joined to her unwise attempts to advance her own family, induced a crisis which resulted in the assassination of the king and queen 11 June 1903. See SERVIA.

Alexander, Abraham, American agitator: b. North Carolina, 1718; d. 1786. His place in history is due to the fact that he was chairman

of the convention which on 31 May 1775 passed the resolutions generally known as the "Mecklenburg Declaration of Independence."

Alexander, Archibald, American clergyman, of Scottish descent: b. Virginia, 17 April 1772; d. Princeton, N. J., 22 Oct. 1851. He studied theology, and performed itinerant missionary work in various parts of Virginia; became president of Hampton-Sidney College in 1796, and pastor of a Presbyterian church in Philadelphia in 1807. On the establishment of Princeton Theological Seminary in 1812 he was appointed its first professor, a position which he held till his death. Among other works he published 'Outlines of the Evidences of Christianity,' 'Treatise on the Canon of the Scriptures' (1826); 'History of the Patriarchs' (1833); and 'History of the Israelitish Nation' (1852); his 'Moral Science' was posthumous.

Alexander, Barton Stone, American soldier: b. Kentucky, 1819; d. San Francisco, Cal., 15 Dec. 1878. He graduated from West Point 1842, and became lieutenant in the engineer corps; as such he superintended the building of Minot's Ledge lighthouse off Boston Harbor, the marine hospital at Chelsea, north of Boston, and the military asylum at Washington, besides repairs on fortifications. He assisted in constructing the defenses of Washington in the Civil War, took part in the first campaign about Manassas, and was brevetted major for conduct at Bull Run; and remaining with the Army of the Potomac was brevetted lieutenant-colonel for conduct at the siege of Yorktown in 1862. In 1864 he was consulting engineer on Sheridan's staff, and in March 1865 was brevetted brigadier-general for services in the war. The next two years he was in charge of the construction of the public works in Maine; and in 1867 became senior engineer with rank of lieutenant-colonel. Thence till death he was a member of the Pacific board of engineers for fortification.

Alexander, Cecil Frances (Humphrey), an Irish poet, born in County Wicklow, 1818: d. 12 Oct. 1895. She was very active in religious and charitable works. She is best known as a writer of hymns and religious poems. Among the most noted are the hymns, 'The Roseate Hue of Early Dawn' and 'All Things Bright and Beautiful.' Her most famous poem is 'The Burial of Moses.'

Alexander, Edward Porter, American military engineer: b. Washington, Ga., 26 May 1835. Graduating from West Point 1857, he was made second lieutenant in the engineer corps; resigned 1861, and entering the Confederate army served there till the surrender at Appomattox, April 1865; at first as chief of ordnance and chief signal officer in the Army of Northern Virginia, then as brigadier-general and chief of artillery in Longstreet's corps, taking part in the Wilderness and Spottsylvania and the siege of Petersburg. From 1866 to 1870 he was professor of mathematics and engineering in the University of South Carolina; thence (1871–92) manager and president of some of the foremost Southern railroads, and is a rice-planter in South Carolina. He was a government director of the Union Pacific R.R. 1885–7; a member of the boards on navigation of the Columbia River and on the Chesapeake-Delaware ship canal 1892–4; and in 1891 engineer arbitrator of the boundary survey between Nicaragua and Costa Rica.

Alexander, James, American colonial lawyer and patriot: b. Scotland about 1690; d. New York, 2 April 1756. He was an engineer officer in Scotland; compelled to leave Great Britain for taking part in the Old Pretender's Rebellion of 1715, he came to Perth Amboy, was its first official recorder in 1718, and was shortly after appointed surveyor-general of New York and New Jersey. Studying law, he rose to distinction at the bar. He engaged in political debate in the press; was temporarily disbarred for serving as counsel to a printer accused of sedition, but was reinstated two years later; held many important public offices, including those of attorney-general and of secretary to the province of New York; acquired a large fortune, and was a zealous upholder of colonial liberties, — he died from the fatigues of a journey from New York to Albany while sick, to oppose a ministerial project threatening colonial rights. With Franklin and others he founded the American Philosophical Society. His son was the famous "Lord Stirling" of the Revolution.

Alexander, Sir James Edward, a British soldier and explorer: b. in Scotland in 1803; d. 2 April 1885; served in the principal wars of his day, particularly distinguishing himself in the Crimean; conducted an exploring expedition into central Africa, and published several narratives of travel. He died 2 April 1885.

Alexander, James Waddell, American clergyman, son of Archibald Alexander: b. near Gordonsville, Va., 13 March 1804; d. 31 July 1859. He studied in Philadelphia, then graduated at Princeton and from its theological seminary. He held a pastorate at Charlotte C. H., Va., 1825–8, and the First Presbyterian Church in Trenton, N. J., 1828–30. Resigning from ill health, he became editor of the Philadelphia *Presbyterian.* He was professor of rhetoric and belles-lettres in Princeton, 1833–44; pastor of the Duane Street Church, New York, 1844–9; professor of ecclesiastical history and church government in Princeton Seminary, 1849–51; from 1851 till death pastor of his old Duane Street Church, reorganized as the Fifth Avenue, corner 19th Street. He wrote much for religious and other periodicals, and for the Tract Society, and over 30 volumes for the American Sunday-School Union. He published also volumes of sermons; 'The American Mechanic and Workingman' (2 vols. 1847); 'Plain Words to a Young Communicant' (1854); a biography of his father (1854); 'Discourses on Christian Faith and Practice' (1858); 'Thoughts on Preaching' (1864); etc

Alexander, John Henry, American scientist: b. Annapolis, Md., 26 June 1812; d. 2 March 1867. Graduating from St. John's College, Annapolis, 1826, he studied law, then engineering; and a plan for the survey of Maryland he put before its legislature gained him the appointment of topographical engineer of the State, which he held till 1841, preparing annual reports which did much to enlist capital in developing its coal and iron fields. He published a two-part 'History of the Metallurgy of Iron,' 1840–2. He was also associated in Hassler and

Bache's coast survey. He made great efforts to establish a uniform standard of weights and measures in the United States, and published in 1850 a 'Universal Dictionary of Weights and Measures, Ancient and Modern.' In 1857 the United States government sent him to England as a delegate to the British commission on international coinage, and his appointment to the directorship of the Philadelphia mint was only prevented by his death. He served on many commissions, and published very valuable reports; papers in the 'American Journal of Science and Arts,' etc. He was also at different times professor of physics in St. James' College, Maryland, the University of Maryland, and the University of Pennsylvania. He also wrote volumes of religious verse, an unpublished 'Dictionary of English Surnames,' etc., and edited scientific works.

Alexander, John White, American artist: b. Alleghany City, Pa., 7 Oct. 1856. For three years he was connected with the art department of the Harpers, and then was three years abroad, studying at the National Academy of Fine Arts, Munich, and with Duveneck in Venice and Florence. Upon his return to the United States he was active as a magazine illustrator. Attention was first attracted to his paintings by his exhibit in the Salon of the Champ de Mars in 1893. He received the gold medal of the Philadelphia Academy of Fine Arts in 1897, and gold medals at the Paris Exposition of 1900, and the Pan-American Exposition, Buffalo, in 1901. In 1902 he was elected an academician of the National Academy. He is represented in the Luxembourg and many American and European collections; and by six lunettes depicting 'The History of the Book' in the east hall of the Congressional Library, Washington.

Alexander, Joseph Addison, American Biblical scholar, son of Archibald Alexander: b. Philadelphia, Pa., 24 April 1809; d. 28 Jan. 1860. He graduated first in the Princeton class of 1826, and with R. B. Patton founded Edgehill Seminary there. He was adjunct professor of ancient languages at Princeton, 1830–3, then spent some years abroad in linguistic studies; from 1838 till death was professor at Princeton Seminary, 1838–50 of Oriental and Biblical literature, 1851–60 of church history and government, 1859–60 of New Testament history and Biblical Greek. He was ranked among the foremost of American Bibliologists, an Orientalist of high order, and a linguist of eminent variety and soundness. His exegetical works include commentaries on Isaiah (1846, 1847, 1851), the Psalms (3 vols. 1850), Acts (1857), Mark (1858), all indebted to German sources. His sermons were collected in 2 vols. 1860.

Alexander, Mrs., pseudonym of Annie Hector (q.v.).

Alexander, Romance of, a romance of the Middle Ages, based on a fabulous account of Alexander's invasion of Asia, written by Callisthenes. In some form it makes a part of all the literatures of Europe and western Asia.

Alexander, Sir William, Earl of Stirling, poet and statesman: b. 1567; d. London 1640. Tutor to Prince Henry, son of James I.; knighted 1609; held various high offices under the crown and in 1621 received the famous and stupendous grant of land embracing what is now Canada and the best portion of the New England States, and given almost absolute authority in its government, a grant that roused bitter envy among his contemporaries. At the coronation of Charles I. (1633) Alexander became Earl of Stirling. His last years were embittered by great pecuniary reverses and he died insolvent. In strength of character, integrity, and many-sidedness he was the greatest Scotchman of his time; took a conspicuous place as scholar, courtier, colonizer, and poet. As a poet he belongs to the type of Fulk Greville and Lord Brooke; his tragedies are labored; but some minor pieces like the 'Aurora' are elegant and musical. Milton read his works, and Addison praised them highly. The earliest editions of them bring high prices and are eagerly sought after. Chief among them are, 'Tragedie of Darius' (1603); 'A Parænesis to the Prince' (1604).

Alexander, William, general in Revolutionary War, known as "Lord Stirling": b. New York, 1726; d. Albany 15 Jan. 1783. He entered the service as a colonel of militia, was taken prisoner at the battle of Long Island, where he commanded a brigade, and served through the New Jersey campaigns with Washington. His claim to the title and estates of Stirling was disallowed by the English House of Lords in 1761, and on his return to America he took an active part in the troubles leading up to the Revolution. He was a member of the first board of governors of King's College, now Columbia University.

Alexander Archipelago, or **Alexander Islands,** a group of islands on the W. coast of North America, extending from 54° 40′ N. to 58° 25′ N.; belong to Alaska Territory. The principal islands are Baranoff and Prince of Wales.

Alexander Land, an area in the Antarctic Ocean, discovered by Bellinghausen in 1821. It is in lat. 68°, lon. 70° to 75°.

Alexander of Hales, a noted English philosopher and theologian: b. Hales, Gloucestershire; d. Paris 1245. One of the greatest of the schoolmen, he was among the first to study Aristotle from the point of view of the Arabic commentators. His chief work was 'The Sum of Theology' (1475).

Alexander of Rumania, Hospodar of Rumania: b. Husch 20 March 1820; d. Heidelberg 15 May 1873. On 29 Jan. 1859 he was chosen hospodar at Jassy and on 17 February at Bukharest, with title Alexander John I. By abolishing serfdom and dividing landed properties he benefited the peasantry, but his efforts toward centralization caused discontent, and on 22 Feb. 1866 he was compelled to abdicate.

Alexander Severus, Roman emperor (in full, MARCUS AURELIUS ALEXANDER SEVERUS): b. Ace (the modern Acre), Phœnicia, 205 A.D.; d. 235. He was the son of Genesius Marcianus and of Julia Mammæa, niece to the Emperor Severus. He was admirably educated by his mother, and was adopted and made Cæsar by his cousin Heliogabalus, then but a few years older than himself, at the prudent instigation of their common grandmother, Mæsa. That con-

temptible emperor, however, soon grew jealous of his cousin and would have destroyed him but for the interference of the prætorian guards, who soon after put Heliogabalus himself to death and raised Alexander to the imperial dignity in his 17th year, 11 March 222. Alexander adopted the noble model of Trajan and the Antonines, and the mode in which he administered the affairs of the empire, and otherwise occupied himself in poetry, philosophy, and literature, is eloquently described by Gibbon. On the whole, he governed ably both in peace and war; but whatever he might owe to the good education given him by his mother, he allowed her a degree of influence in the government which threw a cloud over the latter part of his reign. He himself finally became convinced that in this matter he had allowed his filial reverence to mislead him, and is said to have reproached his mother with his dying breath as the cause of the disaster which had befallen them both. Alexander behaved with great magnanimity in one of the frequent insurrections of the prætorian guards; but, either from fear or necessity, he allowed many of their seditious mutinies to pass unpunished, though in one of them they murdered their prefect, the learned lawyer Ulpian, and in another compelled Dion Cassius the historian, then consul, to retire to Bithynia. At length, after having defeated, in 232, the Persians under Artaxerxes, who wished to drive the Romans from Asia, and undertaking an expedition into Gaul to repress an incursion of the Germans, he was murdered with his mother in an insurrection of his Gallic troops, headed by the brutal and gigantic Thracian, Maximin, who took advantage of their discontent at the emperor's attempts to restore discipline. Alexander was favorable to Christianity, following the predilections of his mother, Julia Mammæa, and he is said to have placed the statue of Jesus Christ in his private temple, with those of Orpheus and Apollonius of Tyana.

Alexander the Great, the third king of Macedon bearing the name which he made so famous: b. Pella, 356 B.C.; d. Babylon, 323 B.C. His mother was Olympias, an Epirote princess, who traced her descent from Achilles. There is little reason to doubt that his father was Philip of Macedon, though the latter was not confident about his paternity, and though there is no evidence of any feelings between the two such as are expected to exist between father and son. On the contrary, Philip seems to have resented the imperial qualities of his son, which he was clever enough to see and appreciate; and Alexander showed a precocious envy of his father's neglected opportunities of conquest, a feeling which the sagacious biographer Plutarch has noted and dwelt on. No open rupture took place till Philip repudiated Olympias to wed a Macedonian lady (Cleopatra according to Plutarch and others, but Eurydice according to Arrian). During the nuptial feasting Philip made at Alexander with his sword, while the son jeered at his father's drunken fury and unsteady gait. In the assassination of Philip in 336 the repudiated and banished Olympias certainly had a hand, and we cannot be sure that Alexander was not an accomplice.

The memorable year in which Alexander first appeared on the stage of universal history was 339 B.C. At the age of 16 the regency of Greece was entrusted to him by Philip when he set out on an expedition against Byzantium; and in that capacity it fell to his lot to lead his first army against an Illyrian rising, to found his first Alexandria in the upper valley of the Strymon, and to receive a deputation of envoys from the king of Persia,— a fit beginning for the miracle of precocity who was afterward to destroy Thebes at 21, to conquer Babylon at 25, and to die master of the world at 33. In the year after his appointment to the regency Alexander showed eminent military capacity at the battle of Chæronea (338), and, on the murder of Philip, ascended the throne in 336, before he had reached his 20th year.

The brilliant natural gifts of Alexander had been developed under the tutelage of Aristotle. His personal beauty, with its ardent expressiveness and flashing eyes, was very remarkable, and he was pre-eminent in horsemanship and all athletic accomplishments. A habit (or perhaps some peculiar muscular conformation of the neck) which gave his head a tilt toward the left shoulder imparted to him an air of hauteur, which gave a note of eminent distinction to manners of charming grace and affability. He was of an extremely trusting disposition. His position in ascending the throne was a difficult one. He had enemies on every side. The Illyrians and Thracians were always watching an opportunity to attack Macedon, and indeed most of the Grecian states were ready, if possible, to throw off the Macedonian yoke. Persia regarded the growth of Macedon with suspicion; and finally his own Macedonian subjects were far from being united in approval of the career of conquest on which Philip and Alexander had both resolved to embark.

His reign began with an act of cruelty such as was destined subsequently to become almost a matter of course on every change of rulers; his uncle and his half-brother were put to death, and the little daughter of Cleopatra, Philip's widow, was butchered in the arms of her mother. In the autumn of 336 Alexander marched into Greece, and was confirmed in the chief command against Persia by the Amphictyones at Thermopylæ. In 335 he advanced to the Hæmus range (the Balkans), and showed great ability in his campaign against the Thracians, crossing the Danube — apparently out of mere bravado — in the face of the enemy without losing a single man. He had no real friends among the Greek states. The Thebans, hearing a false report of his death, became overt enemies, proclaimed their independence, and slew some Macedonian officers. Alexander appeared in Bœotia with amazing dispatch, and took Thebes by storm on the third day of the siege. This was the occasion on which, in the words of Milton,

> "The great Emathian conqueror bade spare
> The house of Pindar."

Leaving Antipater to govern in Europe, he crossed over into Asia in the spring of 334 with 30,000 foot and 5,000 horse. The Persian empire, the conquest of which he undertook, was at least 50 times as large as his own, and numbered about 20 times as many inhabitants. It extended from the Hellespont to the Punjab, from Lake Aral to the cataracts of the Nile.

But it was a vast congeries of subject provinces having no internal bond, and no principle of cohesion but the will of the king. For 80 years it had been tending to dissolution in its western provinces, which were the most exposed to danger. As stages in this process may be mentioned the revolt of Egypt under Amyrtæus in 410, and that of the Cypriote Evagoras, which was not put down till 383; the numerous revolts of satraps, of Greek cities, and of semi-Greek tyrants during the first half of the 5th century; and the attack on Persia made by Tachos, king of Egypt, in 361. It has been well remarked by Adolf Holm that the position of the Persian empire when attacked by Alexander had some resemblance to that of the Roman empire when overrun by the Germans. Both empires held together merely by the law of inertia; in both their strength lay not in their native elements, but in mercenaries taken from the very peoples, the Germans and the Greeks, who threatened respectively the safety of the two empires. Alexander proposed to himself nothing short of complete dispossession of Darius in favor of himself as captain-general of Hellas, and the establishment of his own Panhellenic empire in the room of the Persian. He was not led from point to point by this or that strategical reason. His business was not to leave Asia till every satrapy in the Persian empire acknowledged his sway. Even the burning of the Persian capital Persepolis was probably no act of drunken folly, as which it has often been described, but rather a signal and emphatic assertion of mastery and ownership, as of one who should say, "The Persian empire is mine, to throw it into the fire if I please." Alexander had no intention of remaining king of Macedon. His design was to be the Greek emperor of Europe and Asia; and this position in effect he assumed on the death of Darius. With this view throughout his whole career in Asia he sought as much as possible to fuse and commingle his Asiatic and European subjects, very much as England did in India. This was the project to which he was giving all his efforts at the time of his death.

The first hostile army he encountered was on the Granicus River (an affluent of the Sea of Marmora). He crossed the Granicus, just as he afterward crossed the Pinarus at Issus, in full view of the enemy, hurled himself with all his force on their centre and completely broke it up. It was not his way to refrain from the pass in *quart* till he had first hit in *tierce*. His victories sometimes remind us of the oft-quoted *C'est magnifique, mais ce n'est pas la guerre.* He won by an impetuous dash a victory which a subtler strategy might have failed to achieve, just as his sword-cut at Gordium made away with the knot which his fingers could not undo. The victory at Granicus was attended with unprecedented results; Sardes, Miletus, Ephesus, Halicarnassus submitted one after another, and he established in them democracies of the Greek type. In November, 333, Darius, eager to meet the invader, hastened to the sea-coast near Issus (at the head of the Gulf of Iskanderoon). The tactics pursued at the Granicus had here again a successful issue. Darius fled, leaving his family and his treasures in the hands of the conqueror. The mother, wife, two daughters, and son of Darius were treated with a clemency which foreshadowed the ages of chivalry. An Asiatic conqueror would have put the males to death, probably with torture, and would have sent the females to his harem. Captive Greek generals he also spared and liberated. He took possession of Damascus, a city which even then could boast of a hoary antiquity, and secured all the towns along the Mediterranean Sea. His plan now was to occupy Egypt, and this was made easy by the capture of Tyre on 20 Aug. 332, after a siege of seven months. During the siege a message came from Darius offering Alexander 10,000 talents, the hand of his daughter in marriage, and Asia as far as the Euphrates, if he would make peace. "I would accept it if I were Alexander," said his general, Parmenio. "So would I," replied Alexander, "if I were Parmenio." Gaza fell in November, 332, and Alexander, taking possession of Egypt, sacrificed to Apis and the Egyptian gods in Memphis, and held musical and athletic competitions after the Greek fashion in Tyre. Thus he conciliated the affections of his subjects. Politically he organized Egypt as a province in a way which, as Arrian remarks, foreshadowed the Roman system, giving the civil administration first to two, and then to a single governor, while the troops were placed under several separate commanders. It was now that Alexander founded the celebrated Alexandria — destined in two generations to be the first city in the Levant — and marched through the Libyan desert to consult the oracle of Jupiter Ammon, whose son he claimed to be.

Meantime Darius was collecting an army in Assyria; but before the decisive battle of Arbela he made overtures of peace to Alexander, whose answer was, "I, Alexander, hold all thy treasure and all thy land to be mine," — a verbal cutting of the Gordian knot. The Persian force encountered by the Greeks at Gaugamela, near the ancient Nineveh, and about 50 miles from Arbela (which strangely has given its name to the battle ever since), is said to have numbered 1,000,000 infantry, 40,000 cavalry, 200 scythed chariots, and 15 elephants. Alexander had only 40,000 foot and 7,000 horse, but he won a decisive victory on 1 Oct. 331. The Macedonians aimed at the faces of their adversaries, as the Cæsarians afterward did at Pharsalus. Babylon and Susa opened their gates to the conqueror, who then entered Persepolis, the capital of the province of Persis, seized its immense treasures, and burned its palace and citadel to the ground.

In the spring of 330 Alexander proceeded to Media in pursuit of Darius. That weak monarch was being carried about by Bessus, satrap of Bactria, who, on hearing of the approach of Alexander, inflicted a mortal wound on Darius and fled, leaving him to die. Darius died before Alexander came up with him (July, 330). The conqueror sent his body to Persepolis to be interred with royal honors. After taking possession of Hyrcania and Bactriana he was meditating still more gigantic plans, when he learned in the autumn of 330 that Philotas, the son of Parmenio, though cognizant of a conspiracy against his life, had not reported it. He put both Philotas and Parmenio to death. The execution of the former has been condemned, but is on the whole defensible; the murder of the latter is an inexcusable act of brutal tyranny. About the end

of 330 or the beginning of 329 he crossed the great range of the Caucasus (not the modern Caucasus, but the Hindu Kush) by a pass at an altitude of 13,200 feet — a march comparable with that of Hannibal over the Alps. He reached the city of Bactra (Balkh), and made his way north as far as the Jaxartes or Tanais, where he founded a city, probably the modern Khojend.

He remained in these regions till the summer of 327, spending the winter in Nautaca, on the right bank of the Oxus. Here occurred the murder of Clitus, and Alexander's marriage with Roxana, daughter of Oxyartes, a satrap of Sogdiana. She had a son named after his father in 323. After the death of Alexander she compassed the destruction of his other wife, the daughter of Darius, and was killed with her son in 311 by Cassander. The murder of Clitus has been regarded as a great blot on the career of Alexander. But the circumstances in which he was placed greatly extenuate the act. The East believed in the divinity of Alexander, and such a belief was almost an essential condition of the permanence of his empire. When one of his own officers openly denied and ridiculed the emperor's pretensions at a state banquet he seriously imperiled the Hellenic *raj*. The empire of Alexander was never subject to a second single emperor. The destinies of the West awaited the struggle between Rome and Carthage. But his vast empire nowhere save in India reverted to the pre-Alexandrine type.

Alexander now formed the idea of conquering India. He passed the Indus in 327, and formed an alliance with Taxiles, under whose guidance he reached the Hydaspes (modern Jhelum). This river he crossed after a severe struggle with Porus, in whom he met an opponent very superior to the Persian satraps who had hitherto confronted him or rather retreated before him. He then moved farther east and crossed the Acesines (Chenab) and the Hyraotes (Ravi), and reached the Hyphasis (Beas), which now joins the last river of the Punjab, the Sutlej, but which then flowed in a different channel. He never reached the Sutlej itself. The murmurs of his army compelled him to return. The fine instrument which he had fashioned so dexterously broke in his hand. He recrossed the Acesines to the Hydaspes, where he completed the cities of Nicæa and Bucephala (named after his famous horse Bucephalus), which he had already begun. He had only seen the fringe of India — the Punjab. The wondrous country of Brahma and Buddha never felt the sway of Secundar. It was the only land which, on his departure, reverted to its condition before his arrival. He was obliged to content himself with writing his name large across the histories of Hellenic, Semitic, Egyptian, and Iranian civilization. Alexander's name does not appear in Sanskrit literature.

When he had reached the Hydaspes he built a fleet, in which he sent part of his army down the river, while the rest proceeded along the banks. The city of the Malli, where Alexander was wounded, is probably Multan; Puttala is perhaps Haidarabad. The march of 500 miles through the hideous desert of Gedrosia (Baluchistan), and the voyage of Nearchus, have given much material to romancers and rhetoricians. At Carmania he was joined by Craterus, who had marched through the Bolan Pass to Kandahar, and by Nearchus, whose voyage, then thought so marvelous a feat, is no more than the short steam run from Karachi to Bunder Abbas. From Carmania he went to Pasargadæ, and thence to Susa, where he devoted himself with great energy to the task of uniting as far as possible the Macedonian and Persian nations. He himself married two Persian princesses, and he gave rewards to those of his staff who followed his example in contracting Persian alliances. He sent home to Macedonia, with a present of a talent each, about 10,000 Macedonians who by age or wounds were incapacitated for service. These veterans were led by Craterus, who was sent to succeed Antipater as governor of Europe. Antipater seems to have fallen into disfavor, though in 330 he had done service in defeating Agis, the Spartan king who threatened Megalopolis. It was of this exploit that Alexander contemptuously observed, "So there has been a battle of the mice in Arcadia, while we have been conquering Asia."

In 323 Alexander arrived at Babylon, where he found numberless envoys from nations near and far, come to pay their homage to the young conqueror. He was engaged in very extensive plans for the future, including the conquest of Arabia and the reorganization of the army, when he fell ill of a fever, shortly after the death of his beloved Hephæstion, which had deeply affected him. He died in 323, after a reign of 12 years and 8 months. The day before a rumor had gone abroad that the great general was dead, and that his friends were concealing the truth. The dying king caused his army to defile past his bed, and feebly waved them a last farewell. Alexander was a great administrator, a second Pericles in his devotion to work, an Alcibiades in his distinguished presence, a Phocion in his simplicity of character.

Alexander Yaroslavitch Nevski, a Russian hero and saint, the son of the Grand Duke Jaroslav: b. Vladimir, 1219; d. 1263. In order to defend the empire, which was attacked on all sides, but especially by the Mongols, Jaroslav quitted Novgorod and left the charge of the government to his sons, Fedor and Alexander, the former of whom soon afterward died. Alexander repulsed the assailants. Russia, nevertheless, came under the Mongolian dominion in 1238. Alexander, when Prince of Novgorod, defended the western frontier against the Danes, Swedes, and Knights of the Teutonic Order. He gained, in 1240, a splendid victory on the Neva over the Swedes, and thence received his surname. He overcame in 1243 the Livonian Knights of the Sword, on the ice of Lake Peipus. After the death of his father in 1247 Alexander became Prince of Novgorod, and, on the death of his brother Andreas, Grand Prince of Vladimir. The gratitude of his countrymen has commemorated the hero in popular songs and raised him to the dignity of a saint. Peter the Great honored his memory by the erection of a splendid monastery in St. Petersburg, on the spot where Alexander gained his victory, and by establishing the order of Alexander Nevskoi.

Alexandra Caroline Marie Charlotte Louise Julie, queen of England: b. 1 Dec. 1844; daughter of Christian IX. of Denmark, and wife of Edward VII., whom she married

10 March 1863. She has had three sons, two of whom are dead, and three daughters.

Alexandretta (the ancient ALEXANDRIA AD ISSUM), a small seaport in Syria, on the S.E. coast of the Gulf of Iskanderoon. It is the natural port of Aleppo and northern Syria. The town is rendered unhealthy by the surrounding marshes, but this has been partially remedied by draining one of the largest. The port is a fine bay, running southeast from the Gulf. The imports are chiefly grain, rice, and salt; the exports, galls, silk, cotton, and dips or beshmet (a preparation from grapes, used by the natives as food). Pop. about 3,000.

Alexandria (ISKANDERIEH of the Turks), an ancient city and seaport in Egypt, about 14 miles west of the Canopic mouth of the Nile, on the ridge of land between the sea and the bed of the old Lake Mareotis. Ancient Alexandria was founded by, and named in honor of, Alexander the Great, in 332 B.C., on the site of a village called Rakôtis or Racoudah. Its plan was sketched by the architect Dinocrates. It stood nearly on the site of the present town, though the configuration of the land has altered considerably since then, was 15 miles in circumference, and had 300,000 free inhabitants and at least an equal number of slaves. The Romans ranked it next to their own capital, and when captured by Amru, general of the Caliph Omar (A.D. 641) it contained "4,000 palaces, 4,000 baths, 400 theatres or places of amusement, 12,000 shops for the sale of vegetables, and 40,000 tributary Jews" (Gibbon). The city was regularly built and traversed by two principal streets, each 100 feet wide and one of them 4 miles long. It consisted of two quarters, *Rakōtis*, or the people's quarter, and *Brucheion*, or the quarter of the palace. One fourth of the area upon which it was built was covered with temples, palaces, and public buildings, the most conspicuous being the famous lighthouse upon the little island of Pharos, which was connected with the city by a mole; the splendid temple of Jupiter Serapis; the Library, at that time the richest in the world; the Museum, a kind of academy in which learned men of every description were entertained at the expense of the state; an immense hippodrome; numerous obelisks and pillars, among which were Pompey's Pillar, or more properly Diocletian's Pillar, and the two obelisks known as Cleopatra's Needles. Pompey's Pillar occupies an eminence 1,800 feet to the south of the present walls; its total height is 98 feet 9 inches; the Needles, of red granite, and 70 feet high, stood on the edge of the eastern harbor. One was taken to London in 1878; the other stands in Central Park, New York. The city was bombarded by the British 11 July 1882. (See EGYPT.)

The present city is chiefly built on the mole, which has been increased by alluvial deposits till it has become a broad neck of land between the two harbors. The European quarter swarms with cafés, shops, and theatres, lighted with gas. The castle stands near the old Pharos, and the handsome new lighthouse has a revolving light visible at a distance of 20 miles. Recent improvements, undertaken at a cost of $10,000,000, are expected to make the western or the old harbor by far one of the best and most spacious on the Mediterranean. There is railway communication with Cairo and Suez; the Mahmoudieh canal, made by Mehemet Ali, connects Alexandria with the Nile. Pop. (1902) about 400,000.

Alexandria, Ind., a city in Madison co., on the Cleveland, C., C. & St. L., and Lake Erie & W. R.R.'s, 45 miles N.E. of Indianapolis. It is in a natural gas region and has large window glass and lamp chimney factories, and manufactures of paper, steel, axes, and mineral wool. It has municipal water and lighting plants; churches, schools, banks, and daily, tri-weekly, and weekly newspapers. It was settled in 1837 and is governed by a mayor, elected for four years, and a council of six members. Pop (1890) 715; (1900) 7,221.

Alexandria, La., a town of Rapides parish about 100 miles N.W. of Baton Rouge on the Red River, in the centre of the State, in the midst of a fine farming country. It is becoming quite a railroad centre, the following roads having entered the town: Texas & Pacific, St. Louis, Iron Mountain & Southern, Southern Pacific, St. Louis, Watkins & Gulf, Louisiana Railway & Navigation Co. It has a number of institutions of learning, a $50,000 public school building, and a convent of the Sisters of Mercy. It has a number of miles of asphalt street paving. The State has recently erected an institution for the insane here. The town does a good wholesale and retail business, and has a good trade in molasses, hides, sugar, cotton, and lumber. Here in 1864 a dam was built by Lieut.-Col. Bailey, by which a Federal squadron during Banks' expedition was enabled to pass the rapids. Pop. (1904) est. 10,000.

Alexandria, Va., city, port of entry, and county-seat of Alexandria co.; situated on the Potomac River, the Pennsylvania & So. R.R.'s, and trolley line connecting with Washington, D. C., and Mt. Vernon; 6 m. S. of Washington. The river here expands to the width of a mile and gives the city an excellent harbor that will accommodate the largest vessels. The city is an important trade centre; has manufactures aggregating $20,000,000 annually, and is noted for its educational institutions, which include Washington High School, Potomac, Mt. Vernon, and St. Mary's Academies, and near by the Theological Seminary and High School of the Diocese of Virginia (Protestant Episcopal). There are four national banks, public school property valued at $35,000, and daily and weekly periodicals. Gen. Braddock made his headquarters here in 1775, and in 1861 Col. Ellsworth, an officer in Maj.-Gen. McDowell's army, was shot after tearing down a Confederate flag which floated from the Marshall House. Pop. (1900) 14,528.

Alexandria Bay, N. Y., a village in Jefferson co., on the Rome, W. & O. R.R., about 70 m. N. E. of Oswego. It is a prominent resort of the Thousand Islands. Pop. (1900) 1,511.

Alexandrian Age, or **School**, the school or period of Greek literature and learning that existed at Alexandria in Egypt during the 300 years that the rule of the Ptolemies lasted (323–30 B.C.), and continued under the Roman supremacy. Ptolemy Soter founded the famous library of Alexandria (see below) and his son, Philadelphus, established a kind of academy of sciences and arts. Many scholars and men of genius were thus attracted to Alexandria, and

MAHMOUDIEH CANAL, AT ALEXANDRIA, EGYPT.

a period of literary activity set in which made Alexandria for long the focus and centre of Greek culture and intellectual effort. It must be admitted, however, that originality was not a characteristic of the Alexandrian age, which was stronger in criticism, grammar, and science than in pure literature. Among the grammarians and critics were Zenodotus, Eratosthenes, Aristophanes, Aristarchus, and Zoilus, proverbial as a captious critic. Their merit is to have collected, edited, and preserved the existing monuments of Greek literature. To the poets belong Apollonius, Lycophron, Aratus, Nicander, Euphorion, Callimachus, Theocritus, Philetas, etc. Among those who pursued mathematics, physics, and astronomy was Euclid, the father of scientific geometry; Archimedes, great in physics and mechanics; Apollonius of Perga, whose work on conic sections still exists; Nicomachus, the first scientific arithmetician; and (under the Romans) the astronomer and geographer Ptolemy. Alexandria also was distinguished in philosophical speculation, and it was here that the New Platonic school was established at the close of the 2d century after Christ by Ammonius of Alexandria (about 193 A.D.), whose disciples were Plotinus and Origen. Being for the most part Orientals, formed by the study of Greek learning, the writings of the New Platonists are strikingly characterized — for example, those of Ammonius Saccas, Plotinus, Iamblicus, Porphyrius — by a mixture of Asiatic and European elements. The principal Gnostic systems also had their origin in Alexandria.

Alexandrian Library, a remarkable collection of books, the largest of the ancient world, was founded by the first Ptolemy and fostered by his son. It quickly grew, and already in the time of the first Ptolemy, Demetrius Phalereus had 50,000 volumes or rolls under his care. During its most flourishing period, under the direction of Zenodotus, Aristarchus of Byzantium, Callimachus, Apollonius Rhodius, and others, it is said to have contained 490,000, or, according to another authority, including all duplicates, as many as 700,000 volumes. The greater part of this library, which embraced the collected literature of Rome, Greece, India, and Egypt, was contained in the famous Museum, in the quarter of Alexandria called the Brucheion. During the siege of Alexandria by Julius Cæsar this part of the library was destroyed by fire; but it was afterward replaced by the collection of Pergamos, which was presented to Cleopatra by Mark Antony. The other part of the library was kept in the Serapeum, the temple of Jupiter Serapis, where it remained till the time of Theodosius the Great. When this emperor permitted all the heathen temples in the Roman empire to be destroyed, the magnificent temple of Jupiter Serapis was not spared. A mob of fanatic Christians, led on by the Archbishop Theophilus, stormed and destroyed the temple, together, it is most likely, with the greater part of its literary treasures, in 391 A.D. It was at this time that the destruction of the library was begun, and not at the taking of Alexandria by the Arabs under the Caliph Omar, in 641. There are strong reasons for believing that no library then existed there.

Cf. Petit-Radel, 'Recherches sur les Bibliothèques Anciennes et Modernes' (1819); Ritschl, 'Die Alexandrinische Bibliothek' (1838): Weniger, 'Das Alexandrinische Museum' (1875).

Alexandrian Version, or **Codex Alexandrinus** (Codex A.), a Greek manuscript of the Bible, now in the British Museum, of great importance in Biblical criticism. It is on parchment, with uncial letters, without breathings and accents or spaces between the words. It was written probably in the middle of the 5th century, and contains, in four volumes, small folio, the whole Greek Bible, two letters of Bishop Clement of Rome to the Corinthians, the genuine epistle and a fragment of the second, the spurious one, and eight psalms of Solomon, so called. The first three volumes contain the translation of the Old Testament; the fourth, the New Testament. A large part of the Gospel of St. Matthew and of the Second Epistle to the Corinthians, as well as a portion of the Gospel of St. John, are wanting. The patriarch of Constantinople, Cyrillus Lucaris, who in 1628 sent this manuscript as a present to Charles I., said he had received it from Egypt; and it is evident from other circumstances that it was written there. But it cannot be decided with certainty whether it came from Alexandria (whence its name). It is said, however, to have belonged to the patriarch of Alexandria at the end of the 11th century. John Ernest Grabe followed it in his edition of the Septuagint (Oxford, 1707–20, folio, 4 vols.). Dr. Woide published the New Testament (London, folio, 1786), with types cast for the purpose, page for page and line for line, as in the manuscript itself. A somewhat more accurate text of the New Testament in ordinary Greek type (with the lacunæ supplied) was published by R. H. Cowper in 1860. Henry Hervey Baber edited a facsimile edition of the Old Testament (London 1816–28, 3 vols. folio.). In 1864 the complete text, along with three other of the oldest texts of the Bible, was published at Oxford, the work being arranged in parallel columns. An autotype facsimile of the whole codex in four volumes was published by the British Museum in 1879–83. The text of this manuscript is of most importance in the criticism of the Epistles of the New Testament; in the Gospels the text is not so good.

Alexandrine, the name of a verse, which consists of 6 feet (or of 6½ with female rhymes), equal to 12 syllables, the pause being in correct Alexandrines always on the 6th syllable; for example, the second of the following verses (from Pope's Essay on Criticism):

"A needless Alexandrine ends the song
That, like a wounded snake, drags its slow length along."

The only complete English poem of literary importance written in this measure is Drayton's 'Polyolbion.' The concluding line of the Spenserian stanza is an Alexandrine. The French in their epics and dramas are confined to this verse, which for this reason is called by them the Heroic. The Alexandrine derives its name from an old French poem belonging to the middle of the 12th or the beginning of the 13th century, the subject of which is Alexander the Great, and in which this verse was first made use of.

Alexandrite, a variety of the mineral chrysoberyl (q.v.). It occurs in twin crystals (trillings) and is chiefly remarkable for the fact that while by daylight its color is a dark emerald to grayish-green, it assumes a beautiful columbine-red color by artificial light. Because of this property, and owing to its rarity and great hardness (8.5), it is highly prized as a gem. Its name, given in honor of Alexander II. of Russia, seems singularly appropriate when it is recalled that the gem is said to have been first discovered in the emerald mines of Takowaja, Siberia, on the very day on which the then heir apparent attained his majority, and further that the green and red colors of alexandrite are the national colors of Russia. The finest alexandrites still come from Siberia, but good gems are occasionally found in Ceylon.

Alexandropol (formerly GUMRI), a Russian town and fortress in the trans-Caucasian government of Erivan, situated on a bare plateau near the highway from Erivan to Kars. There is accommodation in the military quarters for a force of 10,000 men. The town has several churches and caravanserais, and there are extensive silk manufactories. Pop. 32,078.

Alexia. See APHASIA.

Alexiad, a life of the emperor Alexis Comnenus (q.v.) by the Princess Anna Comnena, his daughter. This work, which is one of the most important authorities for the history of the closing years of the 11th century, is written in modern Greek and divided into 15 books. It gives a vivid picture of the First Crusade.

Alexian Brothers. See CELLITES.

Alexis, a Greek comic poet, a native of Thurii, in Magna Græcia, afterward an Athenian citizen: b. about 394 B.C., and is known to have lived as late at least as 288 B.C. He was the uncle and instructor of Menander, and is said to have written 245 plays.

Alexis, Wilibald, pseudonym of Wilhelm Häring (q.v.).

Alexis Mikhailovitch, second Russian czar of the line of Romanof. See RUSSIA.

Alexis Petrovitch, the eldest son of the czar Peter the Great and Eudoxia Lapuchin: b. in Moscow, 1690. He oppcsed the innovations introduced by his father, who on this account determined to disinherit him. Alexis renounced the crown, and when Peter set out on his second journey he made his escape in 1717 to Vienna, where he sought the protection of his brother-in-law, the German emperor, and thence to Naples, under the pretext of going to his father, who had sent for him. At the command of Peter he returned; but the enraged czar, regarding his flight as an act of treason, disinherited him by a ukase of 2 Feb. 1718; and when he discovered that Alexis was paving the way to succeed to the crown he not only caused all the participators of his project to be punished capitally or otherwise, but had his son also condemned to death, and the sentence read to him, as pronounced unanimously by 144 judges. Although he was soon afterward pardoned, the fright and anxiety which he had experienced affected him so much that he died in the course of four days, 7 July 1718. It is supposed by some that he was poisoned. He left a daughter and a son, afterward the emperor Peter II.

Alexius (COMNENUS), emperor of Constantinople: b. 1048; d. 15 Aug. 1118. He was the third son of John Comnenus, the emperor Isaac's brother. Naturally clever, he was carefully educated under the direction of his mother; and at the age of 14 took part in an engagement with some European adventurers commanded by a Scot called Russel de Balliol, of whom the youthful warrior afterward became an intimate friend. After several successive emperors had tasted for a brief season the «bitter sweets» of a nominal supremacy over a country torn by anarchy, Alexius, with the aid of the army, was proclaimed emperor, seized on Constantinople, which he permitted his soldiers to pillage, and shut up the nominal ruler in a monastery (1081). The empire was then in a deplorable state. The Turks were profiting by these intestine dissensions to seize upon the Asiatic provinces while Robert Guiscard and his Normans were menacing the west, and fierce swarms from beyond the Danube threatened the nearer provinces. However, Alexius did not despair; he sent supplies of money to his ally Henry IV. of Germany to enable him to attack Rome, the Pope (Gregory VII.) being a firm friend of the Norman leader. His Holiness had to flee, and Guiscard hastened to his aid, leaving in Greece his son Bohemond, who gained two victories over Alexius; but famine and disease weakened the Norman army, which Robert could not rejoin, as he was detained in Italy by a revolt of his vassals. In 1084 he returned to the charge, and after gaining some advantages he suddenly died of an epidemic; although some ascribe his death to poison administered by one of Alexius' secret agents. In consequence of this event the Normans abandoned all their conquests, and Alexius turned his attention to the Turks and Scythians, whom, after an arduous struggle, he completely defeated. Scarcely was this accomplished when, in 1096, the bands of the first Crusade arrived at Constantinople demanding aid, rudely menacing him in his own palace, and finally compelling him to join them. The alliance did not last long; a war broke out between the emperor and the Crusaders, which ended in the defeat of the latter. The rest of Alexius' life was employed in consolidating his conquests and restoring orderly government in his states, which were much disturbed by heresies. He died at 70, after a reign of 37 years. He extended his empire; and for its defense he left to his successors a well-disciplined army, which he had wholly created himself. Historians differ respecting his conduct and abilities; his daughter Anna wrote his life (the Alexiad).

Alfalfa, also called LUCERNE (q.v.) (*Medicago sativa*), is a herbaceous plant belonging to the natural order *Leguminosæ*. The leaves are pinnate-trifoliate; its flowers small, generally purple in color, situated in the axillary spikes. The plant is a native of Asia, but has been cultivated in Europe since before the time of Christ. The Spaniards introduced it into South America, but it did not reach North America until some time between 1850 and 1860, when it was introduced into California. Since then it has become the most extensively cultivated forage crop in the United States. Its adaptability to varying conditions of soil

and climate gives it an extensive range, extending from the arid lands of the West, where irrigation is required, to the richer soils of the East, and from sea-level to heights of over 7,000 feet. It will not flourish in extremely damp or clayey soils. Its roots strike to great depths, so that it withstands droughts better than most of the forage plants. It is cut when coming into bloom, and yields from 3 to 12 tons of hay to each acre. In some regions it is cut every month in the year. It is particularly valuable as a green manure, as it takes nitrogen from the air, and its deep-growing roots draw from the lower soils large quantities of lime, phosphoric acid, potash, and other minerals useful as crop foods. Alfalfa is relished by cattle whether green, as hay, or as ensilage, but to secure the best results it should be fed with root crops and grain, which add the ingredients needed for a well-balanced ration. Alfalfa is subject to two fungus diseases, one on the leaf and another on the root, either of which, if not checked, will spread and ultimately ruin the field. The ‘Farmers' Bulletins,’ issued by the Department of Agriculture at Washington and the various State Experimental Stations, give full information on the culture of the plant and the treatment of its diseases.

Alfarabi, an eminent Arabian philosopher of the 10th century, was a native of Farab, in Asia Minor, his proper name being Abu Nasr Mohammed ben Mohammed ben Tarkhan; died at Damascus in 950. His works consist of treatises on different parts of the Aristotelian philosophy. He excelled in music and philology as well as in philosophy; and one of his most famous works is a kind of encyclopædia, in which he gives a brief account and definition of all branches of science and art. The manuscript of this is in the Escurial. His works were printed at Paris in 1638.

Alfieri, Vittorio, Count: b. Asti, in Piedmont, in 1749, of a rich and distinguished family. His early education was very defective, like that of most men of his rank and country at that time. He died 8 Oct. 1803. At the age of 16 he joined a provincial regiment which was only called together a few days during the year. For some years he led a restless and dissatisfied life, traveling in Italy, France, England, Holland, and then through the countries of northern Europe. He next left the military service, and driven by ennui tried among many other things to write dramatic poetry, and met with great success, his first play, ‘Cleopatra,’ put on the stage in 1775, being received with general applause. He now determined at the age of 27 years to devote all his efforts to attaining a position among writers of tragic poetry. Sensible of his deficiencies, he went to work zealously to educate himself. In seven years he composed 14 tragedies, studied Latin and Tuscan, and even, in his 48th year, made himself master of Greek. At Florence he became intimate with the Countess of Albany, wife of Prince Charles Edward Stuart, a daughter of the House of Stolberg. His passion had the effect of stimulating him to strive more earnestly after poetic fame. To continue his labors in a free and independent manner, he broke the last tie that bound him to his country; and making over all his fortune to his sister, save a moderate income for himself, he lived by turns in Florence and Rome. Prince Charles now dying, Alfieri married his widow, and changed his places of abode to Alsace and Paris. He was at Paris when the Revolution broke out, but after 10 Aug. 1792, returned to Florence. In the troubles of that stormy time he lost his books and the greater part of the complete editions of his tragedies, published by Didot in five volumes. He worked hard to the day of his death. He was buried in the Church of Santa Croce, at Florence, between Macchiavelli and Michael Angelo, where a beautiful monument by Canova covers his remains. Alfieri's tragedies are full of lofty and patriotic sentiments, but the language is bare and stiff, and the plots barren. Nevertheless he is the first tragic writer of Italy, and has served as a model for those who have followed him. His comedies display the same faults in a yet more glaring manner. His ‘Abel’ is the most successful of all his dramatic works. This he called a *tramelogedia* — a name as novel as the work itself, which is intermediate between tragedy and opera. Besides his dramas, Alfieri composed an epic poem, lyrics, satires, and poetical translations from the ancient classics. His autobiography, a striking exhibition of his character, appeared after his death. His complete works were published at Padua in 1809–11, in 37 volumes.

Alfonsine Tables. See ALFONSO X.

Alfon'so, the name of a number of Portuguese and Spanish kings.

Alfonso I., the Conqueror, first king of Portugal, son of Henry of Burgundy, the conqueror, and first Count of Portugal: b. 1110; fought successfully against the Spaniards and the Moors; named himself king of Portugal, and was recognized as such by the Pope; d. 1185.

Alfonso I., king of Naples and Sicily. See ALFONSO V. (of Aragon).

Alfonso V., the African, king of Portugal, succeeded his father, Edward I., 1438. Conquered Tangiers; d. 1481. During his reign Prince Henry the Navigator continued the important voyages of discovery already begun by the Portuguese. Under him was drawn up an important code of laws.

Alfonso X., king of Castile and Leon, surnamed the Astronomer, the Philosopher, or the Wise: b. 1226; succeeded to the throne 1252; d. 1284. Being grandson of Philip of Hohenstaufen, son of Frederick Barbarossa, he endeavored to have himself elected emperor of Germany, and in 1257 succeeded in dividing the election with Richard, Earl of Cornwall. On Richard's death in 1272 he again unsuccessfully contested the imperial crown. Meantime his throne was endangered by conspiracies of the nobles and the attacks of the Moors. The Moors he conquered, but his domestic troubles were less easily overcome, and he was finally dethroned by his son Sancho, and died two years after, 1284. Alfonso was the most learned prince of his age. Under his direction or superintendence were drawn up a celebrated code of laws, valuable astronomical tables which go under his name (Alfonsine Tables), the first general history of Spain in the Castilian tongue, and a Spanish translation of the Bible.

Alfonso V., king of Aragon: b. 1385; d. 1458. He was the son of Ferdinand I. of Aragon, the throne of which he ascended in 1416, ruling also over Sicily and the island of Sardinia. Queen Joanna of Naples had promised to make him her heir, but at her death in 1435 had left her dominions to René of Anjou. Alfonso now proceeded to take possession of Naples by force, which he succeeded in doing in 1442, and reigned till his death in 1458. He was an enlightened patron of literary men, by whom, in the latter part of his reign, his court was thronged.

Alfonso XII., king of Spain. He was the only son of Queen Isabella II. and her cousin, Francis of Assisi, was born in 1857 and died in 1885. He left Spain with his mother when she was driven from the throne by the revolution of 1868, and till 1874 resided partly in France, partly in Austria. In the latter year he studied for a time at the English military college, Sandhurst, being then known as Prince of the Asturias. His mother had given up her claims to the throne in 1870 in his favor, and in 1874 Alfonso came forward himself as claimant, and in the end of the year was proclaimed by General Martinez Campos as king. He now passed over into Spain and was enthusiastically received, most of the Spaniards being by this time tired of the republican government, which had failed to put down the Carlist party. Alfonso was successful in bringing the Carlist struggle to an end (1876), and henceforth he reigned with little disturbance. He married first his cousin, Maria de las Mercedes, daughter of the Duke de Montpensier; second, Maria Christina, Archduchess of Austria, whom he left a widow with two daughters, a son (Alfonso XIII.) being born posthumously.

Alfonso XIII., king of Spain, son of Alfonso XII. and Maria Christina, daughter of Karl Ferdinand, Archduke of Austria: b. after his father's death, 17 May 1886, succeeding by his birth, being a male, his eldest sister. His mother was made queen regent during his minority. On 17 May 1902 the young king formally acceded to the throne and took the oath prescribed by the constitution, the queen regent having taken official leave of the ministry on the 12th. The United States was represented at the ceremony by special envoy. The President sent the king a cordial message.

Alford, Henry, an English poet and miscellaneous writer, philologist, critic, artist, and preacher: b. London, 7 Oct. 1810; d. in Canterbury, 12 Jan. 1871. He became Dean of Canterbury in 1856. An accomplished man, his literary work attracted attention in several departments. Besides sermons and university lectures, he wrote 'The School of the Heart, and Other Poems' (1835), his most popular volume of verse; 'The Queen's English' (1866). He was best known by his celebrated edition of the Greek New Testament (1844–52), which, incorporating the results of German Biblical scholarship, formed a landmark in New Testament study in England and America. He was the first editor of the 'Contemporary Review.'

Alfred, N. Y., a village of 756 population, in Allegany co., on the Erie R.R., 12 m. from Hornellsville. It is noted as being the headquarters in America of the Seventh-Day Baptists, and as the seat of Alfred University, a co-educational (non-sectarian) institution, organized in 1836 as a school, incorporated as a university in 1857. Professors and instructors, 26; students, 215; volumes in the library, 12,136; value of grounds and buildings, $90,000; 800 graduates; total endowment is $450,000.

Alfred, or **Aluredus, of Beverley,** chronicler: flourished 1143. His 'Nine Books of Annals or History of the British Kingdoms to 1129' is largely devoted to the fabulous history of Britain. It is of no use to the historical student, as it adds nothing to what is found in earlier authorities. The best manuscript of the work is among the Hengwet MSS., and has never been printed. Hearn printed an inferior Bodleian MS. in 1716.

Alfred the Great, king of the West Saxons, and foremost figure in early English history: b. Wantage, 849; d. and buried in Winchester, 28 Oct. 901. Separated from the mass of myth and legend that has clustered about the name of this great king, the following are the known facts of his life, or those which the best scholarship agrees upon as being well authenticated. The fifth and youngest son of Æthelwulf and Osburh, he was sent to Rome in 853, remaining there and at the court of Charles the Bold for several years. The impressions received during this Continental experience and education unquestionably helped to give him that international temper and freedom from narrow insularism which so marked him among the men of his time. Little is recorded of him during the reigns of his brothers Æthelbald and Æthelberht, but when he became next in line of succession under Æthelred (866) he was clearly second only in importance to the king himself, a fact attested by his holding the high office of *Secundarius*. In 868 he married Ealhswith, daughter of ealdorman Æthelred the Mickle. In 869 he fought against the Danes at Nottingham, and when the enemy attacked his own Wessex Alfred led the van of his brother's army. Throughout that momentous year of fighting he was easily the leading spirit, taking part in the great victory of Æscesdun (Ashdown), and the later battles of Basing and Merton. Soon after Easter, in the midst of the strife with the Danes, Æthelred died, and Alfred, then only 22 years of age, took his place on the throne. A month later he fought the last battle of the year at Wilton. A series of petty defeats, due to his lack of men, compelled him to make truce, and the withdrawal of the Danes from Wessex was bought upon the usual terms,— a payment of money. For seven years the kingdom had peace. Then the Danish power again broke upon Wessex, overrunning Somerset and Devonshire almost without opposition. About Easter a general resistance began; seven weeks later he defeated the enemy at Ethandun (Edington, Wiltshire), capturing their stronghold. This broke the assailants' spirit; a treaty was concluded with the Danish leader, Guthrum, and Alfred regained all of his own kingdom, added to it all southwestern Mercia, and established an overlordship over the lands ceded to the Danes. Alfred and Wessex became the sole English power in Britain. In 884 Guthrum, with a Danish and

Scandinavian force, landed in Kent and attacked Rochester. Alfred drove them to their ships. In 886 he occupied and fortified London, and a general submission to him seems to have followed throughout Britain. During 894–7 the Danes again proved troublesome. For two years there was fighting throughout the country, but the king with his Londoners and South-Saxons made a vigorous resistance, and the invaders, worn out, retired to the Continent. Four years later he died, survived by his wife and five children; two sons, Eadward, his successor, and Æthelward; three daughters, Æthelflæd, the Lady of the Mercians, Ælfthryth, wife of Baldwin, Count of Flanders, and Æthelgifu, Abbess of Shaftesbury.

King Alfred left behind him magnificently concrete results. He converted ill-trained, short-service levies into a thoroughly organized national army, as powerfully effective a fighting machine as it had formerly been ineffective and helpless. He was the only one of his time to realize that the Danish pirates must be fought on the sea as well as on land. He thereupon created a national fleet; built larger ships than had ever before been used for warfare; and so developed his naval force that in time it was fully able to cope with the invaders upon their own element,— the sea.

His ‹ Laws › are but a compilation of the best ones of his predecessors. His own words explain this: « I durst not venture to set down in writing much of my own, for it was unknown to me what of it would please those who should come after us.» « Those things which I met with which seemed to me rightest, those I have gathered together and rejected the others.» The importance of his work was really great, for, with the blending of the codes of Wessex, Mercia, and Kent, the conception of a national law began and the idea of separate systems of tribal customs passed away.

At Alfred's accession learning seemed dead in England. In his own person, as author and translator, he started English prose into vigorous life. His translation of Orosius' ‹ History of the World › (edition with modern English translation by Bosworth, 1851) became the one accessible handbook of English history; he translated Boetius' ‹ Consolation of Philosophy › (edition with modern English translation by S. Fox, 1864), recasting somewhat its pagan doctrines; the ‹ Pastoral Care › of Gregory the Great (text and translation by H. Sweet, 1871–2); and his English version of Beda's ‹ Ecclesiastical History › perhaps suggested a greater work. This was that unique and priceless possession of the English race, ‹ The Anglo-Saxon Chronicle,› which, without much doubt, was at his bidding put into the shape in which it has come down to us. For the years of his own reign it is a detailed contemporary narrative of the highest value. It is to his efforts, to what he preserved, what he wrote, and to what his example and support encouraged others to write, that England has a richer and earlier vernacular literature than any other Western European nation. For his title of « Great » there is no ancient authority, its use going no further back than the 17th century. He never needed it, for his countrymen and the world know no other of the name with whom it is possible to confound his.

The biography of Alfred by his friend Asser is our chief authority for the king's life. Though its authenticity has been questioned, modern scholars accept it. A Latin edition is printed in Petrie and Sharpe's ‹ Monumenta Historica Britannica › (1848), and an English translation may be found in J. A. Giles' ‹ Six Old English Chronicles › (1848). There are modern ‹ Lives › by J. A. Giles (1848; 2d ed. 1854), R. Pauli (1853), and T. Hughes (1869). Freeman's ‹ Old English History › (1883) and ‹ Norman Conquest › (1870–6) may be consulted with profit, and Stubbs' ‹ Constitutional History of England › (Vol. I.) gives the constitutional aspect of Alfred's reign. A most attractive account is to be found in the chapters of patriotic panegyric in Green's ‹ Conquest of England.›

Algæ, a term popularly restricted to marine cryptogamous plants or seaweeds, but which may be generally defined as comprehending all aquatic flowerless plants, whether growing in fresh or salt water, belonging to the class Thallophytes. The only absolute distinction between the Algæ and the remaining Thallophytes or Fungi is that the former contain chlorophyll, while the latter do not. The higher forms have stems bearing leaf-like expansions, and they are often attached to rocks by roots. A stem is most frequently absent. The plants are nourished through their whole surface by the medium in which they live. They vary in size from the microscopic diatoms to forms whose stems resemble those of forest trees, and whose fronds rival the leaves of the palm. They are entirely composed of cellular tissue, and many are edible and nutritious, as carrageen or Irish moss, dulse, etc. Kelp, iodine, and bromine are products of various species. Coulter distinguishes four groups: the blue-green algæ (*Cyanophyceæ*), green algæ (*Chlorophyceæ*), brown algæ (*Phæophyceæ*), and red algæ (*Rhodophyceæ*).

Algar'di, Alessandro, one of the chief Italian sculptors of the 17th century: b. 1602; d. 1654. He lived and worked chiefly at Rome; executed the tomb of Leo XI. in St. Peter's, and a marble relief with life-size figures over the altar of St. Leo there.

Algarotti, Francesco, äl-gä-rŏt'ē, frän-ches'kō, **Count,** Italian author: b. Venice 12 Dec. 1712; d. Pisa 3 March 1764. His ‹ Plurality of Worlds › (1733), a popular exposition for ladies of Newton's philosophy, established his fame. Till 1739 he lived much in France and became intimate with Voltaire. The study of French literature and contact with its leading representatives exercised a marked influence on his style. His contemporaries greatly respected his art judgments, and his ‹ Essays on the Fine Arts,› in Italian (Germ. tr. 1760), show keen discernment. Frederick the Great held him in high regard, created him count, and ordered a monument built to his memory in Pisa. The best edition of his works is in 17 vols., Venice, 1791–4.

Algarovill'a, the seed-pods of one or two South American trees (genus *Prosōpis*), valuable as containing much tannin

Algarve, or **Faro,** a maritime province of Portugal, extending across the southern coast of the kingdom, bounded north by the prov-

ince of Alemtejo, east by the Spanish province of Huelva, south and west by the Atlantic Ocean. It has a mountainous surface, with some fertile tracts, in which excellent oil, wine, figs, and almonds are produced, and a coast indented with good bays and harbors. Its tunny and sardine fisheries are productive. Faro is its capital. The area is 2,099 sq. m. Pop. 229,000.

Algazzali, or **Alghazzâlî, Abu Hamed Mohammed,** an Arabian philosopher, Persian by birth: b. Tûs in Khorasan in 1058 or 1059; d. 1111. He first taught theology at Bagdad, but left his chair and traveled in Syria, and lived for some time in Damascus, after which he returned to Persia and resumed teaching. The details of his life given by biographers are numerous but contradictory. He was one of the most prolific of the Arabian authors. One of his writings, called the 'Destruction of the Philosophers,' was answered by Averroes in a book entitled the 'Destruction of the Destruction.' He also wrote several moral treatises. Algazzali, as a disciple of the Sufis, was an opponent of the prevailing Aristotelian philosophy of the day, and predisposed to the mystical dogmas of emanation, to which, after a keen and critical study of philosophy, he entirely resigned himself. See Dugat's 'Histoire des Philosophes et des Théologiens Musulmans' (Paris, 1878).

Algebra, Elementary. Any determinate body of entities or symbols subject to a logically consistent system of laws of operation or combination gives rise to a theory called an algebra. Accordingly there are various algebras, as the algebra of quaternions, the algebra of logic, linear algebra, the algebra of relations, the algebra of operations or of groups, multiple algebra, etc., and two algebras may differ in respect to either content or form or both. The subject-matter of ordinary algebra, with which this writing is concerned, consists of the entities known as numbers, whether real or complex (imaginary), the interrelations and properties of the entities and the laws in conformity with which they admit of combination or operation. As appears from the definition, the use of symbols to denote the entities, relations, and operations is not essential to the conception of algebra, although to its development such use is, on grounds of economy, practically indispensable. The evolution of the number system, one may say of the number concept in its wider generality, has been very slow and very long. For an account of the historical development and for citation of its literature, the reader is referred to the article HISTORY OF ELEMENTARY ALGEBRA. On the scientific side, algebra has no more escaped the minute refinements of modern criticism than have other branches of mathematics or of science and thought in general. Speaking generally, the desideratum has been to apply the Razor of Occam to hypothesis and to deduce the doctrine from the smallest number of the simplest and most fundamental data. All mathematics, all science, originates in common sense. It has been justly said that mathematics is common sense refined, etherealized. It is the aim of this article, in so far as space limitations allow, to present the elements of algebra in that aspect, to exhibit it as growing under the stimuli of need and curiosity from a soil of common experience, as the product of powers that are universal among men.

Elementary Faculties and Notions. — Every normal person has the power to form the notions, *thing* and *things*; the notion, *thing composed of things, i.e.*, the notion of collection or assemblage (see *General Theory of Assemblages*); and the notion of *correspondence*, of associating a thing or things with a thing or things, as a name with an object. These notions are neither absolutely simple nor absolutely fundamental (possibly there are no such notions), but relatively they are very simple and very fundamental, and it will be seen that they play an all-important rôle as basis of the concept and doctrine of number.

Simple Properties of Assemblages.—For explanation of the terms element, assemblage, one-to-one correspondence, equivalence (or sameness of power) of assemblages, part and proper part, see GENERAL THEORY OF ASSEMBLAGES. Assemblages will be denoted by large Roman, elements by small Greek, letters. Departures from that rule will be such as need cause no obscurity. The questionable «notion» of assemblage of *all* things is not here admitted. Hence no A contains everything. If a thing β not in A be put in, there arises $B = A + \beta$, where $+$ (plus) denotes the introduction of β, and $=$ means that B and $A + \beta$ are the same. The inverse, removing β from B, yields $B - \beta = A$, where $-$ (minus) means such removal. The elements common to A and B constitute their *intersection*. Thus, if A is all red flowers and B is all roses, the intersection of A and B is all red roses. Any proper part B of A is the intersection of B and A. In that case, $A + B = A$; *e.g.*, all rectangles + all squares = all rectangles. If A is the intersection of B and C, then $B + C = B + (C - A)$; the parenthesis signifies that $C - A$ is to be taken as a whole; *e.g.*, all men + all Europeans = all men + (all Europeans − European men). But $(B + C) - A$ is not the same as $B + (C - A)$, for plainly (all men + all Europeans) − all European men is not the same as all men + all Europeans. If, however, B and C have no intersection and A is part of C, then $(B + C) - A = B + (C - A)$; and, if C is part of B, and A is part of C, then $B - (C - A) = (B - C) + A$. In all cases, $(A + B) + C = A + (B + C)$, $A + B = B + A$. If $A \backsim B$, *i.e.*, if A and B are equivalent, and if α is not in A and β not in B, then $A + \alpha \backsim B + \beta$. So, too, are $A - \alpha$ and $B - \beta$ if α is in A, β in B, and if $A \backsim B$.

Cardinal Number Defined.—It is essential to distinguish between power and sameness of power or equivalence. The *power* (*Mächtigkeit*) of an A is the *new* assemblage yielded by disregarding (abstracting from) both the *character* and the *order* of A's elements. (See *General Theory of Assemblages.*) The new assemblage, $\overline{\overline{A}}$, is called the (cardinal) *number* of A. The number of A is thus an *orderless* assemblage of *characterless* elements (*units*). Every A has an $\overline{\overline{A}}$; and all equivalent A's have the same $\overline{\overline{A}}$, and conversely. Hence the number $\overline{\overline{A}}$ of an A is sometimes said to be or to characterize the *class* of all assemblages equivalent to A. How many elements in A or any equivalent assemblage? *Answer:* $\overline{\overline{A}}$.

Greater and Less Cardinals.—In respect to A and B, it may happen that: (*i*) A has no proper part equivalent to B, but B has a proper part equivalent to A; (*ii*) B has no proper part

equivalent to A, but A has a proper part equivalent to B; (*iii*) A has a proper part equivalent to B and B has a proper part equivalent to A; (*iv*) neither A nor B has a proper part equivalent to the other. If one of the relations holds for A and B, it holds for A' and B' whenever $A \backsim A'$ and $B \backsim B'$. If (*iii*) or (*iv*) is valid for A and B, it follows that $A \backsim B$, thence that $\bar{\bar{A}} = \bar{\bar{B}}$, and conversely; where $=$ means that the cardinals are *equal*, or the same. If (*i*) is valid, A and B are not equivalent, $\bar{\bar{B}}$ is said to be *greater* than $\bar{\bar{A}}$, $\bar{\bar{A}}$ *less* than $\bar{\bar{B}}$; symbolically, $\bar{\bar{B}} > \bar{\bar{A}}$, $\bar{\bar{A}} < \bar{\bar{B}}$. Relation (*ii*), essentially the same as (*i*), needs no further remark. Hence any two cardinals are either equal or one is greater (or less) than the other.

Addition of Cardinals.—Suppose A and B to have no intersection. Their union, assemblage composed of all and only the elements of A and B, is denoted by (A, B). Plainly $\overline{\overline{(A, B)}}$ depends only on $\bar{\bar{A}}$ and $\bar{\bar{B}}$; for $(A, B) \backsim (A', B')$ whenever $A \backsim A'$ and $B \backsim B'$. $\overline{\overline{(A, B)}}$ is called the *sum* of the *summands*, or *addends*, $\bar{\bar{A}}$ and $\bar{\bar{B}}$; symbolically, $\bar{\bar{A}} + \bar{\bar{B}} = \overline{\overline{(A, B)}}$, an equation formally *defining addition* or *summation* of cardinals. How many things in A and B together? *Answer:* $\bar{\bar{A}} + \bar{\bar{B}}$ As a cardinal is *orderless*, addition is *commutative:* $\bar{\bar{A}} + \bar{\bar{B}} = \bar{\bar{B}} + \bar{\bar{A}}$. For the same reason, it is *associative:* $\bar{\bar{A}} + (\bar{\bar{B}} + \bar{\bar{C}}) = (\bar{\bar{A}} + \bar{\bar{B}}) + \bar{\bar{C}}$.

Multiplication.—Associate each element α of A with each element β of B. Denote the assemblage of all pairs so arising by $(A \cdot B)$. $(A \cdot B) \backsim (A' \cdot B')$ whenever $A \backsim A'$ and $B \backsim B'$; hence $\overline{\overline{(A \cdot B)}}$ is determined by $\bar{\bar{A}}$ and $\bar{\bar{B}}$; $\overline{\overline{(A \cdot B)}}$ is called the *product* of the *factors* $\bar{\bar{A}}$ and $\bar{\bar{B}}$; symbolically, $\bar{\bar{A}} \cdot \bar{\bar{B}} = \overline{\overline{(A \cdot B)}}$, *definition* of multiplication of the *multiplicand* $\bar{\bar{A}}$ by the *multiplier* $\bar{\bar{B}}$. A single β taken with each α yields an assemblage A' of pairs such that $\bar{\bar{A'}} = \bar{\bar{A}}$. Each β gives such an A'; in all there are $\bar{\bar{B}}$ such A''s; the union of these is $(A \cdot B)$; hence $\bar{\bar{A}} \cdot \bar{\bar{B}} = \bar{\bar{A}} + \bar{\bar{A}} + \ldots$ where there are $\bar{\bar{B}}$ summands. Hence *multiplication is summation of equal addends.* A cardinal number being orderless, it readily appears that multiplication of cardinals is: *commutative*, $\bar{\bar{A}} \cdot \bar{\bar{B}} = \bar{\bar{B}} \cdot \bar{\bar{A}}$; *associative*, $\bar{\bar{A}} \cdot (\bar{\bar{B}} \cdot \bar{\bar{C}}) = (\bar{\bar{A}} \cdot \bar{\bar{B}}) \cdot \bar{\bar{C}}$; and *distributive*, $\bar{\bar{A}} \cdot (\bar{\bar{B}} + \bar{\bar{C}}) = \bar{\bar{A}} \cdot \bar{\bar{B}} + \bar{\bar{A}} \cdot \bar{\bar{C}}$; where, *e.g.*, $(\bar{\bar{B}} \cdot \bar{\bar{C}})$ means that the product within ( ) is multiplier of $\bar{\bar{A}}$.

Involution.—The continued product of $\bar{\bar{B}}$ equal factors $\bar{\bar{A}}$ is denoted by $\bar{\bar{A}}^{\bar{\bar{B}}}$; *i.e.*, $\bar{\bar{A}} \cdot \bar{\bar{A}} \cdot \bar{\bar{A}} \ldots = \bar{\bar{A}}^{\bar{\bar{B}}}$. Here $\bar{\bar{B}}$ is named *exponent* of $\bar{\bar{A}}$. The continued multiplication of equal factors is called *involution*, and the process of obtaining $\bar{\bar{A}}^{\bar{\bar{B}}}$ is described as *raising* $\bar{\bar{A}}$ *to the* $\bar{\bar{B}}$*th power.* From the definitions involved, the following relations, *laws of exponents*, are found: $\bar{\bar{A}}^{\bar{\bar{B}}} \cdot \bar{\bar{A}}^{\bar{\bar{C}}} = \bar{\bar{A}}^{\bar{\bar{B}} + \bar{\bar{C}}}$; $\bar{\bar{A}}^{\bar{\bar{C}}} \cdot \bar{\bar{B}}^{\bar{\bar{C}}} = (\overline{\overline{A \cdot B}})^{\bar{\bar{C}}}$; $(\bar{\bar{A}}^{\bar{\bar{B}}})^{\bar{\bar{C}}} = \bar{\bar{A}}^{\bar{\bar{B}} \cdot \bar{\bar{C}}}$.

Ordinary Cardinals.—If A contains but a single thing α, $\bar{\bar{A}}$ is named *one*, denoted by 1; *i.e.*, $\bar{\bar{A}} = 1$. The symbol $\equiv$ between two assemblage symbols means that these denote the same assemblage. Let $A_1 \equiv (A, \alpha_1)$, union of A, or α, and another thing α_1. Then $\bar{\bar{A}}_1$ is denoted by 2 and named *two*. In like manner $\bar{\bar{A}}_2$ is named *three* and denoted by 3, in case $A_2 \equiv (A_1, \alpha_2)$, α_2 being different from α and α_1. Continuation of the process yields the series 1, 2, 3, 4, . . . , ν, . . . , of symbols, and the corresponding series, *one, two, three, four*, . . . , of names, of the numbers $\bar{\bar{A}}$, $\bar{\bar{A}}_1$, $\bar{\bar{A}}_2$, $\bar{\bar{A}}_3$, . . . Each of these numbers has a *next after* it and, except 1, a *next before* it. It admits of *proof* that the numbers of the series have the properties: no two of them are equal; each is greater than any preceding one, less than any following one; if ν' is next before ν, $\nu = \nu' + 1$; there is no cardinal number at once $> \nu$ and $< \nu + 1$; no number of the series is greater than every other; there is a least cardinal, viz., 1. Any word with its predecessors of the *count* word series, one, two, . . . , constitute an assemblage equivalent to that whose cardinal the word names; hence, *in counting, the word last used tells the number of things counted, no matter in what order.*

Distinction of Finite and Infinite.—If $\bar{\bar{A}} + 1 = \bar{\bar{A}}$, $\bar{\bar{A}}$ is said to be *infinite* or *transfinite*; in the contrary case, *finite*. Denote by N the assemblage: 1, 2, 3, . . . , ν, . . . Every element of N is a *finite* cardinal, and every finite cardinal is in N. But $\bar{\bar{N}}$ itself is *transfinite* for, $(N, \alpha) \backsim N$, where α is not in N: we may pair α with 1, 1 with 2, . . . Hence $\overline{\overline{(N, \alpha)}}$, or $\bar{\bar{N}} + 1$, $= \bar{\bar{N}}$; *i.e.*, the number of the *part* N is equal to the number of the *whole* (N, α). The so-called self-evident truth, the whole is greater than any of its parts, is generally false. It is always valid for finite assemblages, never for infinites. It serves as *discriminant* of the two classes.

The foregoing sketch will serve to indicate briefly something of the simplicity, depth, and generality of the modern doctrine of the cardinal number.

Need of Generalization of Number Concept.—The numbers in N, the finite cardinals, constitute the foundation of arithmetic and algebra. These numbers are necessary but not sufficient. They afford answers to hosts of questions about themselves, but at the same time they stimulate curiosity to ask other hosts that they cannot answer. What number added to itself gives 4? What number multiplied by itself gives 9? For these N has the answers. Not so, however, if we replace 4 and 9 by 5 and 10. If a and b are any two numbers in N, we may

ask: what is their sum? $a+b=?$ Their product? $a\cdot b=?$ (or $ab=?$ or $a\times b=?$) What is the ath or bth power of b or a? $b^a=?$ $a^b=?$ N contains the answer to every such question of addition or multiplication or involution. But the *inverse* operations, subtraction, division, and evolution, yield questions about the cardinals that the latter do not suffice to answer. To answer all such questions, to render the inverse operations always possible, it is necessary to invent or create new *entities* to meet the demands. These entities, once created, constitute a new assemblage. The union of this with N is then a new *enlarged* assemblage or domain of numbers.

Subtraction, Creation of Negatives.—If A is a finite assemblage, B a proper part of A, and R the assemblage left on suppressing B, then, if $\overline{\overline{A}}=a$, $\overline{\overline{B}}=b$, $\overline{\overline{R}}=c$, we write $c=a-b$, formal definition of *subtraction* of *subtrahend* b from *minuend* a, yielding the *difference* c, or $a-b$. From this definition and that of addition, it follows that $c+b=a$. As A is finite and B is proper part of A, $a>b$. What if $B\equiv A$? Then R is *empty*, and c is not in N. We write *zero* (0) for c, so obtaining $a-a=0$. Calling zero a number and treating it like the cardinals, we have $a+0=a$, $a-0=a$. Consider the relation $c=a-b$. If $b>a$, the relation has no *defined* meaning, for c is neither zero nor in N. We *give* it a meaning. Note that c is to be such that $c+b=a$. Let n be any number in N, and define $\bar{n}$ to be such that $n+\bar{n}=0$. The number $\bar{n}$ is called a *negative* integer, usually written with the bar in front; thus, $-n$; in contradistinction, n is called *positive*, and often written $+n$. To every positive integer corresponds a negative. The sum of any such pair is zero. If $c=a-b$, where $b>a$, c now has definite meaning: c is in N', the assemblage of negative integers. For example, if $c=2-7$, $c=-5$, or $\bar{5}$, for $c+7=2$, $\bar{5}+5+2=0+2=2$.

The *growth* of the number concept is noteworthy: first, the numbers in N; next, zero giving the assemblage $E\equiv(N, 0)$; then the negatives, giving $E'\equiv(E, N')$, which suffice to answer every subtraction question about finite cardinals, or positive integers.

Extension of Old Operations to New Numbers.—Curiosity grows by what it feeds upon. Having secured the invention of zero and negative integers, it asks: how operate on them? How combine any two of the numbers now in hand, whether new or old? For the new numbers new rules, any logically consistent set, might be adopted. So would result *another* algebra. That would be lawful but not expedient. Expedience counsels, though necessity does not compel, the retention and extension of the old rules; as, $a+b=b+a$, etc. Expedience prevails. The consequences, though *formally* obtainable, are for beginners best found by some concrete device, as the plotting of the numbers on the a right line:

$$\ldots -3 \quad -2 \quad -1 \quad 0 \quad +1 \quad +2 \quad +3 \ldots$$

For addition and subtraction the new problems are:

(1) $-5+2=?$ $\qquad -a+b=?$
(2) $+2+(-5)=?$ $\qquad +b+(-a)=?$
(3) $-2+(-5)=?$ $\qquad -b+(-a)=?$
(4) $-2-(+5)=?$ $\qquad -b-(+a)=?$
(5) $+2-(-5)=?$ $\qquad +b-(-a)=?$
(6) $-2-(-5)=?$ $\qquad -b-(-a)=?$

Zero is obviously either (both) positive or (and) negative. Old question: $5+2=?$ $a+b=?$ Answer by stepping: begin at 5 or a, step rightward, 2 or b steps: old rule. To answer (1), follow old rule: begin at -5, etc. Hence, $-5+2=-3$; but by old rule, commutative law, $-5+2=2+(-5)$, hence $2+(-5)=-3$; but by definition, $2-5=-3$, hence $2+(-5)=2-5$: the reasoning is *independent* of the particular integers used; hence $-a+b=b+(-a)=b-a$; *i.e.*, to add a negative is to subtract corresponding positive. Analogously one may find: $-b+(-a)=-b-a=-(b+a)$; $b-(-a)=b+a$; $-b-(-a)=-b+a=-(b-a)$. For multiplication, solutions of the like problems are similarly obtainable: $(-a)\cdot b=b\cdot(-a)=-(a\cdot b)$; $(-a)\cdot(-b)=(-b)\cdot(-a)=(a\cdot b)=ab$; $0\cdot b=b\cdot 0=0\cdot(-b)=(-b)\cdot 0=0=0\cdot 0$. If a be in N or N', and if $a=2\cdot b$, where b is in N or N', a is called *even*; otherwise, *odd*. If a is in N' and b in N, then, from the definitions involved, it is seen that a^b is in N or in N' according as b is even or odd; symbolically, $(-a)^b=+a^b$, if b is even, and $(-a)^b=-a^b$, if b is odd. In particular, $(-1)^b=1$ or -1 according as b is even or is odd: $(-a)^b=(-1)^b a^b$, b even or odd. Extension of the old involution notion and its rules to the new numbers yields new symbols such as a^0, $(-a)^0$, a^{-b}, $(-a)^{-b}$, . . . , and corresponding formal relations such as $(-a)^b\cdot(-a)^{-c}=(-a)^{b-c}$, . . . ; of which the meaning in other terms will appear at a subsequent stage.

Operation of Division, the Concept of Fraction.—The numbers in E' suffice to answer all addition, subtraction, and multiplication questions about themselves, but other questions remain, unanswerable in such terms. E' does not enable us to answer the inverse of every multiplication question even about the positive integers, much less about all the numbers in E'. The inverse of multiplication is named *division*. Given a and b, any numbers of E', multiplication asks: $a\cdot b=?$ The answer is in E'. Given a and c, of E', division asks: $a\cdot(?)=c$; for examples, $4\cdot(?)=8$, $4(?)=9$. In general E' fails to answer. To meet the demand, a new *entity*, named *fraction*, to be thenceforth regarded as a number, is created by the definition: $a\cdot\frac{c}{a}=c$, or $\frac{c}{a}\cdot a=c$. The fraction $\frac{c}{a}$ is often written c/a or $c:a$ or $c\div a$; c is *numerator* or *dividend*, a is *denominator* or *divisor*, c and a are the *terms*; c is said to be divided by a, and $\frac{c}{a}$ is the *quotient* of c by a, or *ratio* of c to a. Plainly, the definition fails to determine $\frac{c}{a}$, when $a=0$; for if $\frac{c}{a}=b$, $c=b\cdot a$, but $b\cdot 0=n\cdot 0$. Hence *zero* is *not* admissible as *denominator* (divisor).

Rational Numbers.—The positive and negative integers, zero, and the fractions are together said to constitute the assemblage of *rational* numbers. Obviously all the rationals are (conceivable as) fractions; for, if a be an integer or zero, $a\cdot 1=a$, but $\frac{a}{1}\cdot 1=a$, whence $a=\frac{a}{1}$. The rules for combination of rationals are consistent extensions of those found for the special rationals composing E'. As to signs:

$$+\frac{+a}{+b}=+\frac{-a}{-b}=-\frac{+a}{-b}=-\frac{-a}{+b},$$

$$-\frac{+a}{+b} = +\frac{-a}{+b} = +\frac{+a}{-b} = -\frac{-a}{-b};$$

$$\left(+\frac{a}{b}\right)\cdot\left(-\frac{c}{d}\right) = -\left(\frac{a}{b}\cdot\frac{c}{d}\right),$$

and so on as for integers. Formulæ, or rules, for addition, subtraction, multiplication, and division of rationals (including those not in E') are readily obtained. For example, $\frac{a}{b}\cdot\frac{c}{d}=$? Let $\frac{a}{b}\cdot\frac{c}{d}=x$; then by the definitions involved and the commutative, distributive, and associative laws, one has:

$$\left(\frac{a}{b}\cdot\frac{c}{d}\right)\cdot bd = x\cdot bd;\quad \left(\frac{a}{b}\cdot b\right)\left(\frac{c}{d}\cdot d\right) = x\cdot bd;$$

$$ac = x\cdot bd;\quad \frac{ac}{bd}\cdot bd = ac;\quad \frac{ac}{bd}\cdot bd = x\cdot bd;$$

$\frac{ac}{bd}=x$; $\frac{a}{b}\cdot\frac{c}{d}=\frac{ac}{bd}$, rule for multiplication. Again,

let $\quad \frac{a}{b}+\frac{c}{d}=x$; then $\left(\frac{a}{b}+\frac{c}{d}\right)\cdot bd = x\cdot bd$;

$$\frac{a}{b}bd+\frac{c}{d}bd = x\cdot bd;\quad ad+bc = x\cdot bd;$$

$$\frac{ad+bc}{bd}\cdot bd = ad+bc;\quad \frac{ad+bc}{bd}\cdot bd = x\cdot bd;$$

$\frac{ad+bc}{bd}=x$; $\frac{a}{b}+\frac{c}{d}=\frac{ad+bc}{bd}$, rule for addition (including subtraction). Analogously may be found that $\frac{a}{b}\div\frac{c}{d}=\frac{a}{b}\cdot\frac{d}{c}$; *i.e.*, division is convertible into multiplication. The *absolute* or *numerical* value of a rational is its value regardless of sign; *e.g.*, the numerical value of -4 is 4. Plainly, $\frac{a}{b}=\frac{ad}{bd}$, $\frac{c}{d}=\frac{cb}{db}$; numerically, $\frac{a}{b}$ is greater than, equal to, or less than $\frac{c}{d}$ according as the like relation subsists between ad and bc. In respect to numerical value, there is a rational and hence an infinity of rationals between every two numerically unequal rationals. Any positive is said to be *algebraically* greater than any negative.

Evolution, Radicals, Surds.—The sum, difference, product, or quotient (division by zero being excluded) of any two rationals is a rational. As to these operations, the domain of rationals is closed. Not so, however, if we admit *evolution*. Let $\frac{a}{b}$ be any rational, and n a positive integer. Involution asks: $\left(\frac{a}{b}\right)^n=$? The answer is a rational. But, n being a positive integer and $\frac{c}{d}$ being rational, evolution inverts the question and asks for a number k such that $k^n=\frac{c}{d}$. In general no rational answers. For example, no rational satisfies the relation $k^2=-1$ or the relation $k^2=2$. To meet such needs a new entity, $\sqrt[n]{r}$, r being rational and n a positive integer, is created by the definition: $(\sqrt[n]{r})^n=r$. The entity or symbol $\sqrt[n]{r}$ is named *radical*, or *nth root* of r. The previously unanswerable question is now answerable: $k=\sqrt[n]{\frac{c}{d}}$. If n is even and r negative, $\sqrt[n]{r}$ is called *imaginary* (see THEORY OF FUNCTIONS OF COMPLEX VARIABLE); in particular, $\sqrt[2]{-1}$, or simply $\sqrt{-1}$, denoted by i, is called imaginary *unit*. If n is odd and r negative, or if n is odd or even and r positive, $\sqrt[n]{r}$ is said to be *real*. Obviously any rational is conceivable under the form $(\sqrt[n]{r})^n$; *e.g.*, $3=(\sqrt{3})^2=(\sqrt[3]{3})^3$, etc. Often, too, $\sqrt[n]{r}$ is rational; *e.g.*, $\sqrt{4}=2$, $\sqrt[3]{27}=3$. If $\sqrt[n]{r}$ is real but not a rational, it is named *surd* of *order n*; *e.g.*, $\sqrt{2}$ is a surd of 2d order. That $\sqrt{2}$ is *not* rational is readily shown. It is plainly no integer. If, then, it is rational, $\sqrt{2}=\frac{a}{b}$, where $b>1$ numerically and $\frac{a}{b}$ is in its *lowest terms*, *i.e.*, a and b are *prime* to each other*, *i.e.*, have no common factor except 1 or -1; then $2b=\frac{a^2}{b}$, an integer equal to a non-integer.

Generalized Exponents.—By means of the new numbers, zero, negatives, fractions, radicals (including surds), the notion of exponent, defined for positive cardinals, admits of generalization to include such forms as a^0, $a^{\frac{3}{4}}$, a^{-2}, etc. The question is: What do such forms signify? In themselves they are meaningless. It is man who gives them meaning, subject to the condition that his algebra shall be self-consistent. It will be sufficient to indicate the process. For (positive) cardinals, $a^m\cdot a^n=a^{m+n}$. This law is *imposed* in case a is any number, new or old. Similarly for $(a^m)^n=a^{mn}$ and $a^m\cdot b^m=(ab)^m$. It readily appears that $\frac{a^m}{a^n}=a^{m-n}$, where $m>n$ and a is not zero. What signifies $a^{\frac{1}{b}}$, b being a positive integer? Assume that $a^{\frac{1}{b}}$ satisfies the law, $a^m\cdot a^n=a^{m+n}$. Then $a^{\frac{1}{b}}\cdot a^{\frac{1}{b}}\cdot\ldots$ (to b factors) $=a^{\frac{1}{b}+\frac{1}{b}+\ldots\text{(to } b \text{ terms)}}=a^{\frac{b}{b}}=a^1=a$; *i.e.*, $\left(a^{\frac{1}{b}}\right)^b=a$, but $\left(\sqrt[b]{a}\right)^b=a$, hence $a^{\frac{1}{b}}=\sqrt[b]{a}$; *e.g.*, $\sqrt{2}=2^{\frac{1}{2}}$, $\sqrt[5]{-3}=(-3)^{\frac{1}{5}}$. It similarly follows that $a^{\frac{b}{c}}=\sqrt[c]{a^b}=\left(\sqrt[c]{a}\right)^b$. In like manner, $a^0\cdot a^b=a^{0+b}=a^b$, but $1\cdot a^b=a^b$, hence $a^0=1$. Once more, let b be a positive integer or fraction, then $a^{-b}\cdot a^b=a^{b-b}=a^0=1$; multiplying by $\frac{1}{a^b}$, $a^{-b}=\frac{1}{a^b}$. It then requires and admits of proof that the exponent laws hold good in case the exponents are any rationals. The case where the exponents are not rationals remains for consideration, requiring another order of ideas of which some account follows.

Irrational Numbers.—It has been seen that the surds are irrational. They may be defined by a more general method, available for the

* See Theory of Numbers.

definition of additional irrationals. For example, the arithmetic process (here assumed) for extracting square root yields for $\sqrt{2}$ the endless decimal 1.41421 ... Consider the two endless sequences of rationals: (1) 1, 1.4, 1.41, 1.414, 1.4142, ...; (2) 2, 1.5, 1.42, 1.415, 1.4143, ... Every number of (1) is $<$ every number of (2); it is possible to find in (1) a number m and in (2) a number n such that $n-m<r$, r being a positive rational small at will, chosen in advance. Hence (1) and (2) are said to define, by approaching near at will, some *Definite*, d, as their common *limit*. Plainly d is in neither (1) nor (2). What is d? The sequences (3) and (4) obtained by squaring the numbers of (1) and (2) are clearly related to 2 as (1) and (2) to d; hence d is $\sqrt{2}$. That is, the *irrational* $\sqrt{2}$ is *definable* as *limit* of *rational* sequences. Compare (see ELEMENTARY PURE GEOMETRY) the definition of π, (irrational) ratio of circumference to diameter of circle. The defining method just exemplified is, in generality, as follows: Let A and B be any two sequences of rationals such that: (*i*) every number of B is $>$ every one of A; (*ii*) given any positive rational r, small at will, there are in A and B numbers a and b such that $b-a<r$. Then A and B have a common *limit*, some *definite*, d. Such d may be rational, as 2 in case of (3) and (4). If d be not a rational, it is named *irrational number*. The rationals and the irrationals together constitute the assemblage of *real* numbers (see THEORY OF THE REAL VARIABLE). If a and b are real and $i=\sqrt{-1}$, numbers of the form $a+ib$ are called *complex* (see THEORY OF THE COMPLEX VARIABLE). The complex numbers $a+bi$ and $a-bi$ are said to be *conjugate*. It is found that the real and complex numbers obey the formal laws of operation that control combination of rationals.

Terms, Expressions, Factors, etc.—In algebra numbers, real or complex, are commonly called *quantities*. Any lawful combination, however complicate, of number symbols represents a number or quantity, and is named algebraic *expression*, as 5, $3a$, $\sqrt{7}\,(a^{\frac{1}{2}}-\sqrt[3]{x^2})$, $\dfrac{(m-n)^{\frac{a}{b}}}{x-z\sqrt{w}}$. The parts of an algebraic expression that are connected by the sign + or − are called *terms*. Two or more terms enclosed in *parentheses* () or *brackets* [] or *braces* {} or written under a *vinculum* $\overline{\quad}$ are treated as a whole; thus, $2-(4+6)=2-10$, $3\times\overline{7-5}=3\times 2$, $x-[y-\{z-(x-y-z)\}]=x-[y-\{z-(x-y+z)\}]=x-[y-\{z-x+y-z\}]=x-[y+x-y]=x-x=0$. An expression of more than one term is a *polynomial* or *multinomial*. Expressions of one, two, three terms are respectively *monomial*, *binomial*, *trinomial*; thus, $a-(b-c)$ is binomial, though its equivalent, $a-b+c$, is trinomial. The term fraction is extended to any expression in the *form* of a fraction (as above defined). An expression may be *integral* as to some of its symbols and *fractional* as to others; thus $\dfrac{(x^2-y^2)w^{-4}}{z^3}$ is integral as to x and y, but fractional as to z and w. The like distinction holds in respect to *rational* and *irrational*: thus $x^{\frac{1}{2}}y^2-\sqrt[3]{z^2}$ is rational as to y, irrational as to x and z. In the indicated product of two or more symbols, as $4\times\frac{1}{2}abx$, any partial product is the *coefficient* of the complementary product; thus 4 and $\frac{1}{2}abx$ are coefficients of each other; similarly, for $4\times\frac{1}{2}$ and abx, for $4\times\frac{1}{2}x$ and ab, etc. An expression that is rational and integral as to some symbol, as x, is said to be of degree n in that symbol if its greatest exponent in any term is n; thus $a^2x^5+ba^3x^3-4xa^6+1$ is of degree 5 in x, of degree 6 in a, and of degree 1 in b. An expression rational and integral in two or more symbols is said to be of degree s in those symbols (together) if s is the largest sum of the exponents of those symbols in any term; thus $a^2b^3c-5a^3b^4c^2-7b^2c^3$ is of degree 9 in a, b, c (together). In general, each of two or more expressions is called a factor of their product. In this general sense, $a^{\frac{1}{2}}$ and $a^{\frac{3}{2}}$ are factors of a^2, and so, too, are $\dfrac{a^3}{b}$ and $\dfrac{b}{a}$. In a more restricted sense, the factors of an expression rational and integral as to some letter must themselves be rational and integral as to that letter; thus some factors of a^2b-a^3b are a, a^2, b, ab, a^2b, $1-a$, for division by any of these yields a quotient rational and integral as to a and b. In such cases, factors of lowest degree in any symbol are called simple factors (in that (symbol). A factor of two or more expressions is called a *common factor* of them. The common factor of highest degree is called the ***highest common factor*** (*H.C.F.*); thus the *H.C.F.* of a^3b^2 and a^2b^3 is a^2b^2; of a^2-b^2 and $ac+bc$, it is $a+b$. Every expression is a *multiple* of its factors. A multiple of two or more expressions is called a *common multiple* of them; it is their *lowest common multiple* (*L.C.M.*) if it is the common multiple of lowest degree; thus, the *L.C.M.* of a ab^2c^2 and a^2bc^3 is $a^2b^2c^3$; of $(x-a)(x-b)^2(x-c)^3$ and $(x-a)^4(x-b)(x-c)$ it is $(x-a)^4(x-b)^2(x-c)^3$. It is readily proved that the product of two expressions is equal to that of their *H.C.F.* and *L.C.M.* If E is any algebraic expression, then $E^2, E^3, \ldots, E^n$ are respectively the second, third, ..., nth powers of E, and E is the *square*, *cube*, ..., nth root respectively of $E^2, E^3, \ldots, E^n$. In particular, E^2 and E^3 are the square and the cube of E. Thus ax^2 is the square root of a^2x^4, $\dfrac{a}{b}$ is the cube root of a^3b^{-3}, $x^{\frac{1}{2}}-y^{\frac{1}{2}}$ is the square root of $(x^{\frac{1}{2}}-y^{\frac{1}{2}})^2$, or $x+y-2x^{\frac{1}{2}}y^{\frac{1}{2}}$.

Ratio, Proportion, Variation.—The fraction $\dfrac{a}{b}$ is the *ratio* of a to b, often written $a:b$, of which a is *antecedent* and b is *consequent*. If $a=\dfrac{x}{y}$ and $b=\dfrac{z}{w}$, then $a:b=\dfrac{xw}{yz}$. A ratio is *commensurable* or *incommensurable* according as it is or is not a rational number; thus, 2:5 is commensurable, but $\sqrt{2}:1$, ratio of diagonal to side of square, is incommensurable. Plainly, ratio theory is fraction theory. It is easily proved that if $\dfrac{a}{b}=\dfrac{c}{d}=\dfrac{e}{f}=\ldots$, then $\dfrac{a+c+e+\ldots}{b+d+f+\ldots}=\dfrac{a}{b}$, unless $b+d+f+\ldots=0$. If $\dfrac{a}{b}=\dfrac{c}{d}$, a, b, c, and d, taken in order, are *in proportion*, often written $a:b::c:d$, or $a:b=c:d$, a and d being the *extremes* and b and c the *means*. In such case $ad=bc$, and conversely. If $a:b=b:c$, *i.e.*, if $b^2=ac$, b is a *mean proportional* to a and c, and

c is a *third proportional* to a and b. If $a:b=c:d$, then $a+b:b=c+d:d$, $a-b:b=c-d:d$, whence $a+b:a-b=c+d:c-d$; *i.e.*, a, b, c, d are in proportion by *composition*, by *division*, and by both. A quantity x varies *directly* as y, symbolically $x \propto y$, if the ratio of every two values of x is equal to the ratio of the corresponding y values. If $x \propto 1:y$, x varies *inversely* as y. If $x \propto yz$, x varies as y and z *jointly*. Examples: if x is distance traveled and y is rate, $x \propto y$; if x is volume of given mass of gas (at constant temperature) and y is pressure on it, $x \propto 1:y$ (Boyle's Law); if x is the area of triangle and x and z are base and altitude, $x \propto yz$. If $x \propto y$, $x=cy$, where c is some constant; if $x \propto 1:y$, $x=c:y$; if $x \propto yz$, $x=cyz$, if $x \propto y$ and $\propto 1:z$, $x=cy:z$; if $x \propto y$ and $y \propto z$, $x \propto z$, $x+y \propto z$, $x-y \propto z$, $\sqrt{xy} \propto z$; if $x \propto y$ and $z \propto w$, $xz \propto yw$; if $x \propto y$, $x^k \propto y^k$, k any exponent; if $x \propto y$ when z is constant, and $x \propto z$ when y is constant, then $x \propto yz$ when y and z both vary. It is seen that *variation* is a kind of generalized doctrine of proportion.

The Notion and Notation of Function.—A quantity which may take different values is a *variable.* Two variables so related that to a value of either there corresponds one or more values of the other are called functions of each other (see INFINITESIMAL CALCULUS). Any algebraic expression is a function of the symbols it involves, and conversely; for example, $2x^2+3$ is a function of x, and conversely. A function of a symbol as x is often denoted by the symbol $f(x)$ or $F(x)$ or $\phi(x)$ or the like and read f-function of x, and so on. If $f(x)=2x^2-4$, then $f(0)=-4$, $f(-1)=-2$, $f(a)=2a^2-4$, etc. The function symbol has reference to the *form* of the function, and in the same argument or discussion the same symbol may not be used for two different functions. Of great importance are the integral (entire) polynomials, of which the general form for a single variable x is $f_n(x) \equiv a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \ldots + a_{n-1}x + a_n$. The coefficients a_0, a_1, ..., a_n are regarded as arbitrary constants. Accordingly $f_1(x) \equiv a_0x + a_1$, said to be *linear* or of first degree; $f_2(x) \equiv a_0x^2 + a_1x + a_2$, the general *quadratic* expression or expression of second degree; $f_3 \equiv a_0x^3 + \ldots + a_3$, the general *cubic*, $f_4(x) \equiv a_0x^4 + \ldots + a_4$, the general *biquadratic*, etc. The *general* expressions become *particular* or *special* on assigning specific (numerical) values to the (literal) coefficients. In any $f_n(x)$ any value may be given to x, the corresponding value of $f_n(x)$ is then determined. The inverse problem of determining all values of x for which $f_n(x)$ shall have a prescribed value is far more difficult. A value of x for which $f_n(x)$ is zero is said to cause $f_n(x)$ to *vanish.* To every expression $f_n(x)$ corresponds an equation, $f_n(x)=0$, of 1st, 2d, ..., nth degree, according as $n=1, 2, \ldots, n$. The equation imposes a *condition* on x, restricting its variability, allowing it only such values as make $f_n(x)$ vanish. (The variable in an equation is called the *unknown quantity.*) Any such value is a *root* of the equation. The equation $f_n(x)=0$ has n and only n roots (see THEORY OF EQUATIONS). To *solve* an equation is to find its roots. A linear equation $a_0x+a_1=0$ has one root, $\frac{-a_1}{a_0}$, and it may always be found by adding $-a_1$ to both *members* a_0x+a_1 and 0 and then dividing the sums by a_0. The result of the addition is the equation $a_0x = -a_1$. Obviously any term may be *transposed* from either member of an equation to the other if at the same time the *sign* of the term be reversed. Presently we shall see how to solve *quadratic*, *cubic*, and *biquadratic* equations.

Factor and Remainder Theorems.—Obviously $f_n(x)$ may contain a factor of the form $x-a$; *e.g.*, $x-2$ is a factor of x^2-4. If $f_n(x)$ has $x-a$ for factor, then $f_n(x) \equiv (x-a)Q$, where Q is the quotient of $f_n(x)$ divided by $x-a$. Hence under the supposition $f_n(x)$ vanishes when a is put for x. The converse is the *factor theorem*: If $f_n(x)$ vanishes on replacing the variable x by a number a, then $x-a$ is a factor of $f_n(x)$. Proof: divide $f_n(x)$ by $x-a$ until the remainder R does not contain x. Then $f_n(x) \equiv (x-a)Q+R$; put a for x, then $f_n(a) \equiv (0-0)Q+R$, but $f_n(a)=0$, hence $R=0$, hence $f_n(x) \equiv (x-a)Q$. At the same time is proved the *remainder theorem*: Division of $f_n(x)$ by $x-a$ yields $f_n(a)$ for remainder. By the factor theorem it is seen that x^n-a^n is divisible by $x-a$, for on putting a for x, $x^n-a^n = a^n-a^n=0$. Put a for x in x^n+a^n; the result is not zero; hence $x-a$ is not a factor of x^n+a^n. If n is odd, $x+a$ is a factor of x^n+a^n for $(-a)^n+a^n=0$ for n odd.

The Quadratic Equation.—The general quadratic equation $ax^2+bx+c=0$ can be solved as follows: The roots of an equation are not altered by adding a constant to both members or by multiplying both by a constant. Dividing both members by a, then adding $\frac{b^2}{4a^2}-\frac{b^2}{4a^2}$ to the left member, we obtain $\left(x+\frac{b}{2a}\right)^2-\left(\frac{b^2-4ac}{4a^2}\right)=0$; factoring,

$$\left\{x+\frac{b}{2a}+\frac{1}{2a}\sqrt{b^2-4ac}\right\}\left\{x+\frac{b}{2a}-\frac{1}{2a}\sqrt{b^2-4ac}\right\}=0.$$

If the product of two or more integral factors is zero, one of them must be zero and the equation is *satisfied* if any one of them is zero. Hence the roots of the quadratic are the roots of the linear equations obtained by equating to zero the foregoing factors. The roots r_1 and r_2 are:

$$r_1=\frac{1}{2a}(-b+\sqrt{b^2-4ac}),\ r_2=\frac{1}{2a}(-b-\sqrt{b^2-4ac}).$$

Thus it is seen that every quadratic equation has two and but two roots. Their *sum* $r_1+r_2=-\frac{b}{a}$ and their product $r_1r_2=\frac{c}{a}$, a special case (see THEORY OF EQUATIONS) of the law connecting the roots and coefficients in the general equation $f_n(x)=0$. If the coefficients are real, the roots are both imaginary when and only when the discriminant $b^2-4ac<0$, or negative. If $b^2-4ac=0$ the roots are equal; if b^2-4ac is a perfect square, they are rational.

The Cubic Equation, Cube Roots of Unity.—Let $x^3=1$, then $x^3-1=0$; factoring left member, $(x-1)(x^2+x+1)=0$. Hence the cube roots of unity are 1, $\omega_1=\frac{1}{2}(-1+\sqrt{-3})$, $\omega_2=\frac{1}{2}(-1-\sqrt{-3})$; ω_1 and ω_2 are imaginary (complex); $\omega_1^2=\omega_2$, $\omega_2^2=\omega_1$, $\omega_1^3=\omega_2^3=1$; writing ω for ω_1, the cube roots of 1 are 1, ω, ω^2. Any number a has three cube roots, $\sqrt[3]{a}$, $\omega\sqrt[3]{a}$, $\omega^2\sqrt[3]{a}$; thus the cube roots of 8 are 2, $\omega 2$ and $\omega^2 2$. The general cubic may be written $x^3+ax^2+bx+c=0$. On

putting $y-\frac{a}{3}$ for x, the cubic becomes

$$y^3+\left(b-\frac{a^2}{3}\right)y+\left(c-\frac{ab}{3}+\frac{2a^3}{27}\right)=0,$$

or $y^3+py+q=0$ lacking the second term and called the *reduced* cubic. It is sufficient to solve the reduced cubic, for the roots of the original are then found by the relation $x=y-\frac{a}{3}$. Let $y=z-\frac{p}{3z}$, then $z^6+qz^3-\frac{p^3}{27}=0$. This is *quadratic* in z^3, yielding $z^3=-\frac{q}{2}\pm\sqrt{Q}$ $\left(\text{where } Q=\frac{q^2}{4}+\frac{p^3}{27}\right)$, $z=\sqrt[3]{-\frac{q}{2}\pm\sqrt{Q}}$, $\omega\sqrt[3]{\quad}$, $\omega^2\sqrt[3]{\quad}$. From the fact that z has six values, it must not be inferred that y has six; for the two values z_1^3 and z_2^3 of z^3 are such that $z_1^3z_2^3=-\frac{p^3}{27}$; hence the six z-values, z_1, z_2, ωz_1, ω^2z_2, ωz_2, ω^2z_1, yield but *three* y-values, corresponding to the relations $z_1z_2=\omega z_1\cdot\omega^2z_2=\omega_2z_1\cdot\omega z_2=-\frac{p}{3}$. For example, $y_1=z_1-\frac{p}{3z_1}=z_2-\frac{p}{3z_2}=z_1+z_2$. If

$$z_1=\sqrt[3]{-\frac{q}{2}+\sqrt{Q}},\quad\text{then}\quad z_2=\sqrt[3]{-\frac{q}{2}-\sqrt{Q}},$$

and the y-values are:

$$y_1=\sqrt[3]{-\frac{q}{2}+\sqrt{Q}}+\sqrt[3]{-\frac{q}{2}-\sqrt{Q}},$$

$$y_2=\omega\sqrt[3]{-\frac{q}{2}+\sqrt{Q}}+\omega^2\sqrt[3]{-\frac{q}{2}-\sqrt{Q}},$$

$$y_3=\omega^2\sqrt[3]{-\frac{q}{2}+\sqrt{Q}}+\sqrt[3]{-\frac{q}{2}-\sqrt{Q}}.$$

It can be readily shown for real p and q that one of the y's is real and the other two are conjugate imaginaries if Q be $+$, that all are real and two are equal if $Q=0$, and that all are real and distinct if Q is $-$. The last case is called *irreducible* because the root formula, involving imaginaries, is *practically* valueless. In this case the roots may be found by help of the trigonometric functions (see TRIGONOMETRY) as follows: Let $Q=-r^2\sin^2\theta$, $-\frac{1}{2}q=r\cos\theta$, then $r=\sqrt{-p^3:27}$, $\cos\theta=-\frac{1}{2}q:\sqrt{-p^3:27}$. The value of θ may be found by trigonometric table. Hence

$$\sqrt[3]{-\tfrac{1}{2}q+\sqrt{Q}}=\sqrt[3]{r\cos\theta+ir\sin\theta}$$
$$=\sqrt[3]{r}\{\cos\tfrac{1}{3}(\theta+2k\pi)+i\sin\tfrac{1}{3}(\theta+2k\pi)\}$$

and

$$\sqrt[3]{-\tfrac{1}{2}q-\sqrt{Q}}$$
$$=\sqrt[3]{r}\{\cos\tfrac{1}{3}(\theta+2k\pi)-i\sin\tfrac{1}{3}(\theta+2k\pi),$$

$k=0$, $\frac{1}{2}$, or 1. The y formulæ then give $y=2\sqrt[3]{r}\cos\frac{1}{3}(\theta+2k\pi)$.

The Biquadratic, or Quartic.—In general form this is $x^4+px^3+qx^2+rx+s=0$. The equivalent *reduced* quartic, $x^4+ax^2+bx+c=0$, is found by replacing x by $x-\frac{p}{4}$. To solve the reduced quartic, let $x=u+y+z$, then $x^4-2x^2(u^2+y^2+z^2)-8uyzx+(u^2+y^2+z^2)^2-4(u^2y^2+y^2z^2+z^2u^2)=0$; if this be identical with the reduced quartic, $a=-2(u^2+y^2+z^2)$, $b=-8uyz$, $c=(u^2+y^2+z^2)^2-4(u^2y^2+y^2z^2+z^2u^2)$. Owing to relations between the roots and coefficients of any equation (see THEORY OF EQUATIONS), the roots of the *auxiliary* cubic $t^3+\frac{a}{2}t^2+\frac{a^2-4c}{16}t-\frac{b^2}{64}=0$ are u^2, y^2, z^2. Denoting them by l, m, n, we have $x=\pm\sqrt{l}\pm\sqrt{m}\pm\sqrt{n}$, apparently eight values of x, but really only *four* because the product $uyz=-b:8$. If b is positive the values of x are $-\sqrt{l}-\sqrt{m}-\sqrt{n}$, $-\sqrt{l}+\sqrt{m}+\sqrt{n}$, $\sqrt{l}-\sqrt{m}+\sqrt{n}$, $\sqrt{l}+\sqrt{m}-\sqrt{n}$; if b is negative, they are the negatives of the former.

Historical and Critical Note.—As seen, the general equations of 4th and lower degrees are soluble by means of radicals or root extraction. It was naturally but incorrectly supposed that the same means would prove available in case of the general quintic and equations of higher degree, and one of the great problems of the eighteenth century was to solve the quintic in a manner analogous to that employed above for the quartic, cubic, and quadratic. In 1770 Lagrange proved that the method was not adequate for that purpose, as it gave for *auxiliary* equation an essentially general one of *sixth* degree. By Abel, Wantzel, and Galois (see GALOIS THEORY OF EQUATIONS) it was shown to be impossible to solve by radicals any *general* equation of degree above 4. Subsequently Hermite proved that the roots of the general quintic are expressible in terms of elliptic functions. The quadratic, cubic, and quartic are solvable by other methods than those given above, but all are essentially the same. The solution of the general quadratic was known to the Arabs in the ninth century. The solution of $x^3+px+q=0$ was discovered by Scipio Ferreo in the beginning of the sixteenth century. It was rediscovered a few years later by Tartaglia. The solution given above is known as Cardan's, but it is known that Cardan learned it from Tartaglia. Ferrari, a pupil of Cardan's, solved the quartic. The solution, given by Bombelli in his algebra (1579), is sometimes attributed to him. Descartes gave a different solution in 1637. The solution presented above is Euler's, having been found by him in 1770.

Higher Equations.—Although the *general* equations of the 5th and higher degrees are not solvable by radicals, many *particular* equations of such degrees are thus solvable; *e.g.*, $x^8-1=0$ breaks up into two quartics, $x^4-1=0$, $x^4+1=0$. In works on the theory of equations (see THEORY OF EQUATIONS) various methods, chief of which is Horner's, are given whereby the commensurable roots of any equation having numerical coefficients can be found and the incommensurable roots can be found to any required degree of approximation.

Simultaneous Equations.—The general linear equation in two variables or unknowns, as x and y, is $ax+by=c$. Solved for one of the variables, say x, in terms of the other, the equation becomes $x=\frac{c-by}{a}$. It is seen that x and y are functions of each other: to any value of either corresponds a value of the other. Any two

corresponding values constitute a *pair satisfying* the equation. There are infinitely many such pairs satisfying a given equation of the kind in question, as many pairs as there are numbers. Obviously there are hosts of pairs not satisfying a given equation. All the pairs satisfying a given equation constitute a *system* of pairs. Two equations $a_1x + b_1y = c_1$, $a_2x + b_2y = c_2$ are different unless $a_1 : a_2 = b_1 : b_2 = c_1 : c_2$. Have the two systems determined by two different equations any pairs in common? The answer is, *one* pair. It can be found as follows: Multiplying the former equation by b_2, the latter by $-b_1$, adding and solving for x, $x = (b_2c_1 - b_1c_2) : (a_1b_2 - a_2b_1)$; analogously, $y = (a_2c_1 - c_1a_2) : (a_1b_2 - a_2b_1)$. This and only this pair of values of x and y satisfies *both* equations. In combining the equations, x and y were regarded as the same in both. Two or more equations in two or more unknowns are called *simultaneous* when the unknowns are treated as representing the same numbers in all the equations. In the foregoing solution the x-equation was found by *eliminating y between* the given equations. The elimination was accomplished by *addition*. It might have been done otherwise, as by *comparison*, *i.e.*, solving each equation for y and equating the y-values so obtained, or by *substitution*, *i.e.*, solving one of the equations for y and substituting the y-value so found for y in the other equation. In any of these ways or by combinations of them one may find a triplet of values satisfying three arbitrary equations in three unknowns, x, y, z: eliminate, say z, between two of them and then between the remaining one and one of the others; so result two equations in x and y, to be handled as above. The method is obviously extensible to the case of n equations in n unknowns. In general, n linear equations in n unknowns are satisfied simultaneously by but a single set of values of the unknowns, but in special cases by more than one set. The latter happens only when the coefficients satisfy some special condition or conditions. Under certain conditions n or more equations in $n - 1$ unknowns may be satisfied by a same set of values. Thus $ax + b = 0$ and $cx + d = 0$ have the same root when and only when $bc - ad = 0$; $a_1x + b_1y + c_1 = 0$, $a_2x + b_2y + c_2 = 0$, $a_3x + b_3y + c_3 = 0$, are simultaneously satisfied or are *consistent* when and only when $a_1b_2c_3 + a_2b_3c_1 + a_3b_1c_2 - a_3b_2c_1 - a_2b_1c_3 - a_1b_3c_2 = 0$. For the expression of such conditions, and the solution of sets of linear equations, by means of determinants, see the article DETERMINANTS and works therein cited.

Simultaneous equations involving the unknowns to degrees higher than the first may sometimes be solved. Consider, for example, the pair of equations: $ax + by + c = 0$, $dx^2 + ey^2 + fxy + gx + hy + k = 0$; from the former $y = -(c + ax) : a$; substituting that y-value for y in the second given equation, a quadratic in x is found; this gives two x-values; substituting these in the given linear equation, the two *corresponding* values of y are found. The corresponding values must be properly *paired*; thus the equations $3x + 4y - 5 = 0$ and $2x^2 - xy + y^2 - 22 = 0$ give $x = 3$ and $-109 : 53$, $y = -1$ and $148 : 53$; the proper pairing is $x = 3$, $y = -1$, and $x = -109 : 53$, $y = 148 : 53$; the equations are not satisfied by $x = 3$, $y = 148 : 53$, for example. Once more, the two quadratics $x^2 + 3xy = 28$, $xy + 4y^2 = 8$ give, on division (member by member) and clearing of fractions, $2(x^2 + 3xy) = 7(xy + 4y^2)$; whence $x = 4y$ or $-7y : 2$. For $x = 4y$, the second given equation furnishes $4y^2 + 4y^2 = 8$ and $y = 1$ or -1, whence $x = 4$ or -4; using $x = -7y : 2$ in like manner, one finds $y = +4$ or -4 and $x = -14$ or 14; in all four pairs of values corresponding thus: $x = 4$, $y = 1$; $x = -4$, $y = -1$; $x = 14$, $y = -4$; $x = -14$, $y = 4$. In general, an equation of mth degree and one of nth degree in two unknowns are both satisfied by mn pairs of numbers. The solution of such a pair involves, in general, the solution of an equation of degree mn.

Permutations and Combinations.—Any arrangement (in a row) of r things (regarded as belonging to a set of n things) is called a (straight) *permutation of the n things r at a time.* Two permutations are the same when and only when they consist of the same things in the same order. The number of different (possible) permutations of n things r at a time is often denoted by ${}_nP_r$. To find this number, think of *any* one of the ${}_nP_{r-1}$ permutations of n things $r - 1$ at a time. There remain $n - r + 1$ things. Put one of these after the things of the given permutation. There so results a permutation of the n things r at a time. It readily follows that ${}_nP_r = {}_nP_{r-1} \cdot (n - r + 1)$, ${}_nP_{r-1} = {}_nP_{r-2} \cdot (n - r + 2)$, $\ldots$, ${}_nP_2 = {}_nP_1 \cdot (n - 1)$, ${}_nP_1 = n$. Multiplying these equations member by member, it is found that ${}_nP_r = n(n - 1) \ldots (n - r + 1)$. If $r = n$, ${}_nP_n = n!$, where $n!$ (or $\underline{|n}$) means $1 \times 2 \times 3 \times \ldots \times n$ and is read *factorial n*. It can be readily proved that the number P of permutations of n things $(a, b, c, \ldots)$ n at a time, p of the things being a's, q of them b's, $\ldots$, is $P = \frac{n!}{p!\,q!\ldots}$. If the *order* in a permutation of n things r at a time be disregarded, the result is a *combination* of n things r at a time. Two combinations are the same if they consist of the same elements. A common symbol for the number of combinations of n things r at a time is ${}_nC_r$. By permuting the r things of a combination in every way, $r!$ permutations arise. It follows that ${}_nC_r \cdot r! = {}_nP_r$, whence ${}_nC_r = {}_nP_r : r!$. Since, on taking r things from n things, there remain $n - r$ things, it is seen that ${}_nC_r = {}_nC_{n-r}$.

Arithmetical Progression.—An *A.P.* is a series of numbers such that the difference between any two adjacent terms is the same as that between any other two adjacent terms. The general *A.P.* is: $a, a + d, a + 2d, \ldots, a + \overline{n-1}d$. The theory involves five elements: the common difference, d; the first term, a; the last, l; the number of terms, n; and the sum of the terms, s. Given any three of the elements, the remaining two can be found. Since ${}_5C_3 = 10$, there are but 20 problems to solve, giving rise to as many formulæ. The formula for l in terms of a, d, and n obviously is $l = a + \overline{n-1}d$. To find s in terms of a, l, and n, let $s = a + (a + d) + (a + 2d) + \ldots + (l - 2d) + (l - d) + l$; then $s = l + (l - d) + (l - 2d) + \ldots + (a - 2d) + (a - d) + a$; adding, $2s = n(a + l)$, whence $s = \frac{n}{2}(a + l)$. The remaining eighteen formulæ, completely exhausting the subject, are: $l = -\frac{1}{2}d + \sqrt{2ds + (a - \frac{1}{2}d)^2}$; $l = \frac{2s}{n} - a$; $l = \frac{s}{n} + \frac{(n-1)d}{2}$; $s = \frac{1}{2}n(2a + \overline{n-1}d)$; $s = \frac{l + a}{2} + \frac{l^2 - a^2}{2d}$; $s = \frac{1}{2}n(2l - \overline{n-1}d)$; $a = l - \overline{n-1}d$;

$a = \frac{s}{n} - \frac{1}{2}(n-1)d$; $a = \frac{1}{2}d \pm \sqrt{(l+\frac{1}{2}d)^2 - 2ds}$; $a = \frac{2s}{n} - l$; $d = (l-a) \div (n-1)$; $d = 2(s-an) \div n(n-1)$; $d = (l^2-a^2) \div (2s-l-a)$; $d = 2(nl-s) \div n(n-1)$; $n = 1 + (l-a) \div d$; $n = (d-2a \pm \sqrt{(2a-d)^2+8ds}) \div 2d$; $n = 2s \div (a+l)$; $n = (2l+d \pm \sqrt{(2l+d)^2-8ds}) \div 2d$.

Geometric Progression.—A *G.P.* is a series of numbers such that the ratio of any one to the next is equal to the ratio of any other one to its next. Accordingly, the general form of a *G.P.* is: $a, ar, ar^2, \ldots, ar^{n-1}$. Again, there are five elements to be considered: the first term, a; the last, l; the ratio, r; the number of terms, n; and the sum of the terms, s. In terms of any three of the five elements, either of the remaining elements can be expressed. Accordingly the theory of the *G.P.* involves the solution of but twenty problems. Most important of these are the problems, to express l in terms of a, r, and n, and to express s in terms of a, r, and n. It is plain that l, or the nth term, is $l = ar^{n-1}$. To find s, let $s = a + ar + \ldots + ar^{n-2} + ar^{n-1}$; then $rs = ar + ar^2 + \ldots + ar^{n-1} + ar^n$; subtracting, and dividing by $1-r$, it is found that $s = \frac{a(1-r^n)}{1-r} = \frac{a-rl}{1-r}$. The remaining eighteen formulæ are easily obtained. If r be numerically less than 1, the *G.P.* is said to be a *decreasing G.P.*; otherwise, not. In case of a decreasing *G.P.*, it is possible to *sum the series to infinity*, a phrase requiring explanation. An endless series, $a_1, a_2, \ldots$, is said to be *infinite*, *i.e.*, to contain an infinite number of terms. A series that has an end, a last term, is finite. Let s_n denote the sum of the *first n* terms of an infinite series. If the series be such that there is a finite number L from which, by taking n large enough, s_n may be made to differ by less than any prescribed amount and to which s_n, as n continues to increase, approaches nearer and nearer in value, then L is named *limit of s_n as n increases endlessly*, the series is said to be *convergent* (see SERIES) and L is called the *sum* (to infinity) of the series. Observe that here the word *sum* is used in a new sense, viz., as limit of a sum (in old sense). Now consider the *infinite G.P.*, $a, ar, ar^2, \ldots, ar^{n-1}, ar^n, \ldots$. The sum s_n of the first n terms, by the foregoing formula for s, is: $s_n = \frac{a}{1-r} - \frac{ar^n}{1-r}$. If the *G.P.* is a decreasing one, $r < 1$ numerically, r^n approaches *zero* as *limit* as n increases without bound, and hence s_n has $\frac{a}{1-r}$ for limit, the *G.P.* is a convergent series, and its sum to infinity is $s = \frac{a}{1-r}$. For example, the sum of the infinite series, $1, \frac{1}{2}, \frac{1}{4}, \ldots$, is $s = \frac{1}{1-\frac{1}{2}} = 2$.

Harmonical Progression.—An *H.P.* is a series of numbers such that the series of their reciprocals is an *A.P.* Hence the typical *H.P.* is of the form $\frac{1}{a}, \frac{1}{a+d}, \frac{1}{a+2d}, \ldots, \frac{1}{a+(n-1)d}$. It is obvious that every problem involving an *H.P.* is convertible into a problem involving an *A.P.* If a and b be any two numbers, their *arithmetic mean* is a number c such that the series a, c, b is an *A.P.* Hence $c - a = b - c$, whence $c = \frac{1}{2}(a+b)$; *i.e.*, the arithmetic mean of two numbers is half their sum. The *geometric mean* of a and b is a number c such that the series a, c, b is a *G.P.* Hence $\frac{c}{a} = \frac{b}{c}$, whence $c = \sqrt{ab}$; *i.e.*, the geometric mean of two numbers is the square root of their product. The harmonic mean of a and b is c, where c is such that the series a, c, b is an *H.P.* Hence $\frac{1}{a}, \frac{1}{c}, \frac{1}{b}$ is an *A.P.* Hence $\frac{1}{c} - \frac{1}{a} = \frac{1}{b} - \frac{1}{c}$, whence $c = \frac{2ab}{a+b}$. Denote by A, G, and H respectively the arithmetic, the geometric, and the harmonic means of a and b. Then $A = \frac{1}{2}(a+b)$, $G = \sqrt{ab}$, $H = \frac{2ab}{a+b}$. It is readily seen that $H = G^2 : A$, whence $G = \sqrt{AH}$; *i.e.*, the geometric mean of two numbers is the geometric mean of their arithmetic and their harmonic means.

The Binomial Theorem or Expansion.—If a and b are any numbers and n is any positive integer,

$$(a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{1 \cdot 2}a^{n-2}b^2 + \ldots$$
$$+ \frac{n(n-1)(n-2)\ldots(n-r+1)}{1 \cdot 2 \cdot 3 \cdot \ldots \cdot r}a^r b^{n-r} + \ldots$$
$$+ nab^{n-1} + b^n,$$

an expansion containing $n+1$ terms. For proof of the relationship see article MATHEMATICAL INDUCTION. It can be proved by algebraic means, most readily by Maclaurin's formula (see CALCULUS), that, if a is numerically greater than b and n is any real number, the same expansion as that above given is valid, *i.e.*, $(a+b)^n = a^n + na^{n-1}b + \ldots$, which, however, contains an infinite number of terms, except in the case where n is a positive integer. The equation is called the *binomial theorem*. It was discovered by Sir Isaac Newton, but its correctness was not proved by him. One of the simplest of its countless applications is its application to the problem of finding correct to any required degree of approximation any real root of any real number. For example, suppose it is desired to know the real cube root of 25 correct to five decimal places. We may proceed as follows:

$$\sqrt[3]{25} = (25)^{\frac{1}{3}} = (27-2)^{\frac{1}{3}} = (3^3-2)^{\frac{1}{3}} = (3^3)^{\frac{1}{3}}$$
$$- \tfrac{1}{3}(3^3)^{-\frac{2}{3}}(2) - \tfrac{1}{9}(3^3)^{-\frac{5}{3}}2^2 - \tfrac{5}{81}(3^3)^{-\frac{8}{3}}2^3 - \ldots$$
$$= 3 - \frac{2}{3 \cdot 3^2} - \frac{4}{9 \cdot 3^5} - \frac{40}{81 \cdot 3^8} - \ldots = 2.92402.$$

The Number e and the Series for e^x.—If n be numerically greater than 1, the foregoing theorem yields the equations

$$\left(1 + \frac{1}{n}\right)^n = 1 + 1 + \frac{1 - \frac{1}{n}}{2!} + \frac{\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)}{3!} + \ldots;$$

$$\left(1 + \frac{1}{n}\right)^{nx} = 1 + x + \frac{x\left(x - \frac{1}{n}\right)}{2!} + \frac{x\left(x - \frac{1}{n}\right)\left(x - \frac{2}{n}\right)}{3!} + \ldots.$$

Hence

$$\left\{1 + 1 + \frac{1 - \frac{1}{n}}{2!} + \frac{\left(1 - \frac{1}{n}\right)\left(1 - \frac{2}{n}\right)}{3!} + \ldots\right\}^x$$
$$= 1 + x + \frac{x\left(x - \frac{1}{n}\right)}{2!} + \frac{\left(x - \frac{1}{n}\right)\left(x - \frac{2}{n}\right)}{3!} + \ldots.$$

This equation is valid for every value of n numerically greater than 1. The limits approached by its members as n increases beyond every finite value are equal; *i.e.*,

$$\left(1+1+\frac{1}{2!}+\frac{1}{3!}+\ldots\right)^x=1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\ldots.$$

The series on the right is convergent for every finite value of x; in fact, for any given value of x, the series after a certain number of terms converges more rapidly than any decreasing *G.P.* The series on the left is a special case of that on the right, viz., $x=1$. The *limit* of the sum of the first n terms of the series on the left, *i.e.*, its sum (to infinity) is denoted by e; accordingly the equation may be written: $e^x=1+x+\frac{x^2}{2!}+\frac{x^3}{3!}+\ldots$ The meaning is that the number e raised to a power indicated by a given value of x is the sum to infinity of the series for that value of x. Since $e=1+1+\frac{1}{2!}+\frac{1}{3!}+\ldots$, its approximate value can be readily calculated. That value, correct to ten decimal places, is $e=2.7182818284$. The number e, one of the most important of all numbers, is incommensurable, *i.e.*, not exactly expressible as a rational fraction, and it is *transcendental*, *i.e.*, not a root of an equation $ax^n+bx^{n-1}+\ldots=0$, where the coefficients $a, b, \ldots$ are integers (see GENERAL THEORY OF ASSEMBLAGES).

Logarithms.—Let a be any positive number greater than 1. If $a^x=N$, x is named *logarithm of N to the base a*; symbolically, $x=\log_a N$, or, if the base is supposed known, simply $x=\log N$. If a be fixed, x and N will vary each with the other, each is a function of the other. Since $a^0=1$, $\log 1=0$ no matter what the base. But in general the logarithm of a given number will vary with the base; thus, since $2^4=16$, $4^2=16$, $\log_2 16=4$, $\log_4 16=2$. The general connection can be readily found thus: let $a^x=N$ and $b^y=N$, then $\log_a N=x$ and $\log_b N=y$; also $a^x=b^y$, $a=b^{\frac{y}{x}}$, $\log_b a=\frac{y}{x}=\frac{\log_b N}{\log_a N}$; whence $\log_b N=\log_a N\cdot\log_a b$. Calling a an old and b a new base, it is seen that the logarithm of a given number to a new base is equal to the product of the logarithm of the number to the old base and the logarithm of the new base to the old base. Let $a^x=N$, $a^y=M$, then $a^{x+y}=NM$; hence the logarithm of a product is the sum of the logarithms of the factors. Again, $(a^x)^\kappa=N^\kappa=a^{\kappa x}$; whence it is seen that the logarithm of the κth power of a number is κ times the logarithm of the number. Once more, $\frac{a^x}{a^y}=a^{x-y}$; that is, the logarithm of a fraction is equal to that of the numerator minus that of the denominator. Logarithms to the base 10 are called *common* logarithms or *Briggsian* logarithms, after Briggs, who introduced them in 1615. These are used in practical computation, but in theoretical work logarithms are referred to the number e, the *Napierian* base, so called after *Napier* (1550–1617), the inventor of logarithms.

Let N be any number and n any positive integer. Then $\log_{10}(N\cdot 10^n)=\log_{10}N+n\log_{10}10=n+\log_{10}N$; and $\log_{10}(N\div 10^n)=\log_{10}N-n\log_{10}10=-n+\log_{10}N$. Now multiplication or division by a power of 10 has only the effect of moving the decimal point, while the logarithm of the product, as just seen, is equal to that of the multiplicand (or dividend) increased (or decreased) by an integer. Accordingly, if two numbers differ only in the position of the decimal point, their logarithms differ only in respect to the integral part (called the *characteristic*), the fractional part (called the *mantissa*) being the same in both. In that fact resides the chief practical advantage of the Briggsian system. For example, if $\log_{10}2.23=.3483$, it follows that $\log_{10}22.3=1.3483$; and $\log_{10}.00223=\log_{10}(2.23\div 10^3)=-3+.3483$, or $\bar{3}.3483$, as *negative* characteristics are often written. It is easy to see that the characteristic of a logarithm is $+n$ if the number has $n+1$ figures before the decimal point, and is $-n$ if the number is a pure decimal in which the point is followed by $n-1$ zeros. Thus, $\log_{10}23506.054=4+$a pure decimal, and $\log_{10}.0008953=\bar{4}+$a pure decimal.

Exponential and Logarithmic Series, Calculation of Logarithms.—On replacing x in the series for e^x by $x\log_e a$, there results the *exponential* series, $a^x=1+(\log_e a)x+(\log_e a)^2\frac{x^2}{2!}+\ldots$ In this replace x by y and a by $1+x$. The result is, $(1+x)^y=1+y\log_e(1+x)+\ldots$ Also, if x be numerically less than 1, the binomial theorem gives $(1+x)^y=1+yx+\ldots$ These series being equal for all values of y, the coefficients of like powers of y are equal (see *Undetermined Coefficients*, below). Hence, for $x<1$ numerically, $\log_e(1+x)=x-\frac{x^2}{2}+\frac{x^3}{3}-\frac{x^4}{4}+\frac{x^5}{5}-\ldots$, the *logarithmic* series. Replacing x by $-x$, $\log_e(1-x)=-x-\frac{x^2}{2}-\frac{x^3}{3}-\frac{x^4}{4}-\frac{x^5}{5}-\ldots$ The logarithmic series converges *slowly* for all but small values of x. It is on that account ill adapted to the computation of Napierian logarithms. A series better adapted to such calculation is, however, readily obtained as follows: From the last two series it follows that $\log_e\frac{1+x}{1-x}=2\left(x+\frac{x^3}{3}+\frac{x^5}{5}+\ldots\right)$. Put $x=\frac{m-n}{m+n}$, so that $\frac{1+x}{1-x}=\frac{m}{n}$, then

$$\log_e\frac{m}{n}=2\left\{\frac{m-n}{m+n}+\frac{1}{3}\left(\frac{m-n}{m+n}\right)^3+\frac{1}{5}\left(\frac{m-n}{m+n}\right)^5+\ldots\right\},$$

a rapidly converging series that may be used for the calculation of logarithms as follows. For $m=2$ and $n=1$, we get $\log_e 2=0+2\{\frac{1}{3}+\frac{1}{3}(\frac{1}{3})^3+\ldots\}$, whence $\log_e 2=.693147$ (correct to six decimal places). For $m=3$ and $n=2$, the series gives $\log_e 3=\log_e 2+2\{\frac{1}{5}+\frac{1}{3}(\frac{1}{5})^3+\ldots\}=1.098612$. Taking $m=5$ and $n=3$, it is found that $\log_e 5=1.609438$ Then $\log_e 4=2\log_e 2$, $\log_e 6=\log_e 2+\log_e 3$, $\log_e 8=3\log_e 2$, and so on. In particular $\log_e 10=\log_e 2+\log_e 5=2.302585$. Since $\log_e N=(\log_e N)(\log_e 10)$, it is seen that the common logarithm of any number may be found from the Napierian logarithm of that number by multiplying the latter logarithm by 2.302585 This last is called the *modulus of common logarithms*. It is obviously possible to calculate logarithms that shall be correct to any prescribed number of decimal places. Logarithms correct to 3 or 4 places are sufficiently accurate for all ordinary computations, though tables correct to 5, 6, 7 and even 10 or more places are often employed By means of any such table can be found the logarithm of any given number, and conversely The number corresponding to a given logarithm is often called the *antilogarithm*. The advantage of loga-

rithmic over ordinary computation is easily seen. Thus to find the product of two or more numbers, it suffices to add their logarithms and then to take the antilogarithm of the sum. To extract any root, say the 7th, of any number, it suffices to divide the logarithm of the number by 7 and to take the antilogarithm of the quotient. To find the quotient of two numbers, it suffices to subtract the logarithm of the divisor from that of the dividend and to take the antilogarithm of the difference. The *cologarithm* of a number is the logarithm of the reciprocal; thus, $\operatorname{colog} n = \log \frac{1}{n} = \log 1 - \log n = 0 - \log n$; hence to subtract a logarithm is equivalent to adding the corresponding cologarithm.

Undetermined Coefficients. — Reference was made above to this subject, of which some account will now be given. Let $f(x) \equiv a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \ldots + a_{n-1}x + a_n$, a rational integral function of degree n in x. It can be proved and is here assumed that any such function vanishes for some value of the variable. If $f(r_1) = 0$, then, by the factor theorem, $f(x) \equiv (x - r_1)f'(x)$, where $f'(x) \equiv a_0x^{n-1} + \ldots$ If $f'(r_2) = 0$, then $f'(x) \equiv (x - r_2)f''(x)$, where $f''(x) \equiv a_0x^{n-2} + \ldots$, and hence $f(x) \equiv (x - r_1)(x - r_2)f''(x)$. By the argument here exemplified it is proved that $f(x)$ may be put in the form $f(x) \equiv a_0(x - r_1)(x - r_2) \ldots (x - r_n)$. Each of the n numbers $r_1, r_2, \ldots, r^n$ causes $f(x)$ to vanish; hence the n numbers are roots of the equation $f(x) = 0$. It can be easily seen that the equation $f(x) = 0$ cannot have more than n different roots unless its coefficients are each zero; that is, $f(x)$ cannot vanish for more than n different values of x unless $a_0 = a_1 = \ldots = a_n = 0$. For if $f(r_{n+1}) = 0$, then $a_0(r_{n+1} - r_1)(r_{n+1} - r_2) \ldots (r_{n+1} - r_n) = 0$, but by hypothesis no ( ) $= 0$, hence $a_0 = 0$, and $f(x) = a_1x^{n-1} + \ldots$ As the latter is to vanish for more than $n - 1$ values of x, $a_1 = 0$. In like manner it would follow that $a_2 = 0, \ldots, a_n = 0$. But if the coefficients are each zero, $f(x)$ vanishes for every value of x. If $f(x)$ vanishes for more than n values of x, it vanishes for all values of x. Now suppose that $a_0x^n + a_1x^{n-1} + \ldots + a_n$ is to be equal to $b_0x^n + b_1x^{n-1} + \ldots + b_n$ for all values of x, then the function $(a_0 - b_0)x^n + (a_1 - b_1)x^{n-1} + \ldots + (a_n - b_n)$ must vanish for every value of x, and, consequently, $a_0 = b_0$, $a_1 = b_1, \ldots, a_n = b_n$. Hence two rational integral functions of degree n in x are equal for all values of x, *i.e.*, are *identical*, when and only when the coefficients of like powers of x are equal. This proposition enables us to solve many problems involving the determination of *undetermined coefficients.* For example, suppose it required to find the sum of the squares of the first n integers. Assume the identity $1^2 + 2^2 + \ldots + (n-1)^2 + n^2 \equiv a + bn + cn^2 + dn^3 + en^4 + fn^5 + \ldots$, where the coefficients $a, b, \ldots$ are to be determined. Replacing n by $n+1$, we obtain $1^2 + 2^2 + \ldots + n^2 + (n+1)^2 \equiv a + b(n+1) + c(n+1)^2 + d(n+1)^3 + e(n+1)^4 + \ldots$ By subtracting corresponding members of the identities, there results the identity $n^2 + 2n + 1 \equiv b + 2cn + c + 3dn^2 + 3dn + d + 4en^3 + 6en^2 + 4en + e + \ldots$ As this relation is to be valid for every value of n, coefficients of like powers of n must be equal. Hence $e = 0$, $f = 0, \ldots, 1 = 3d$, $2 = 3d + 2c$, $1 = b + c + d$; hence $b = \frac{1}{6}$, $c = \frac{1}{2}$, $d = \frac{1}{3}$. Accordingly, $1^2 + 2^2 + \ldots + (n-1)^2 + n^2 = a + \frac{1}{6}n + \frac{1}{2}n^2 + \frac{1}{3}n^3$, true for every value of n, hence for $n = 1$, and hence $a = 0$. Therefore $1^2 + 2^2 + \ldots + n^2 = \frac{1}{6}n(n+1)(2n+1)$.

Part-fractions.—The so-called principle of undetermined coefficients has frequent application in the solution of the problem, to decompose a given fraction into part-fractions (commonly called partial fractions) whose sum shall be the given fraction. Any fraction whose terms are rational integral functions of x may be thus decomposed. The method of procedure may be made sufficiently clear by a few examples. It will be observed that the problem is in a sense the inverse of the problem of summing fractions. For example, the sum of $\frac{2}{x}$, $\frac{5}{3(1-x)}$, and $\frac{-1}{3(2+x)}$ is $\frac{x+4}{2x - x^2 - x^3}$ or $\frac{x+4}{x(1-x)(2+x)}$. The inverse problem is: given the latter fraction, to find its components. It is plain that the only fractions whose denominators are linear and whose sum is a fraction of the proper denominator and a linear numerator are $\frac{a}{x}$, $\frac{b}{1-x}$, and $\frac{c}{2+x}$. Hence we assume: $\frac{x+4}{2x - x^2 - x^3} = \frac{a}{x} + \frac{b}{1-x} + \frac{c}{2+x}$, whence

$$x + 4 = a(1-x)(2+x) + bx(2+x) + cx(1-x),$$

which is to be valid for all values of x. Expanding the right-hand member and equating corresponding coefficients on right and left, we obtain: $4 = 2a$, $1 = -a + 2b + c$, $0 = -a + b - c$; whence $a = 2$, $b = \frac{5}{3}$, $c = -\frac{1}{3}$; and the component fractions are seen to be $\frac{2}{x}$, $\frac{5}{3(1-x)}$, $\frac{-1}{3(2+x)}$. For another example, we may take $F \equiv \frac{4x^2 + 3x - 1}{(x-1)^2(x+2)}$. A little reflection suffices to show that the assumption to be made is $F = \frac{a}{x-1} + \frac{b}{(x-1)^2} + \frac{c}{(x+2)}$. Then $4x^2 + 3x - 1 = a(x-1)^2 + b(x-1)(x+2) + c(x+2)$; equating coefficients and solving the resulting equations, it is found that $a = 1$, $b = 3$, $c = 2$. In case a factor of the given denominator is repeated κ times, as in $\frac{N}{(mx+n)^\kappa(px+q)}$, the assumption to be made is: given fraction $= \frac{a_1}{mx+n} + \frac{a_2}{(mx+n)^2} + \ldots + \frac{a_\kappa}{(mx+n)^\kappa} + \frac{b}{(px+q)}$. If F is of the form $\frac{N}{(mx^2+nx+l)^\kappa(px+q)^s(gx+h)}$, then assume $F = \frac{ax+b}{mx^2+nx+l} + \frac{ax+b}{(mx^2+nx+l)^2} + \ldots + \frac{ax+b}{(mx^2+nx+l)^\kappa}$ + etc., as before. If N is of degree equal to or higher than that of the given denominator, F is converted by division into an integral function + a fraction the degree of whose denominator exceeds that of its numerator. The latter fraction is then decomposed by the methods above indicated.

Indeterminate (*Undetermined, Evanescent, Illusory*) *Forms.*—In case of a fraction, $\phi(x) \equiv \frac{f(x)}{F(x)}$, it may happen that both terms vanish for some value of x, as $x = a$, yielding the form $\frac{0}{0}$, which, as division by zero is meaningless, is itself without meaning and is commonly called indeterminate. In such case we are free (logically) to *give* the form a meaning, any meaning or value whatever. But while all meanings (values) are allowable, not all are expedient. For ex-

ample, $\dfrac{x^2-a}{x-a}$ has a definite value for every x-value except $x=a$. For this value the fraction takes the form $\dfrac{0}{0}$. To this we might assign the value of 5 or -3, or any other. But such a choice would be motiveless. On the other hand, $\dfrac{x^2-a^2}{x-a}=x+a$ for all values of x except a; for this *critical* value a, the right member takes a definite value, $2a$, which is accordingly suggested as the value to be naturally assigned to the indeterminate form in this case. The decisive motive for this choice lies yet deeper: it is that as x varies through a sequence of values, say $a+\frac{1}{2}$, $a+\frac{1}{4}$, $a+\frac{1}{8}, \ldots$, having a as limit, the corresponding sequence of fraction-values, $2a+\frac{1}{2}$, $2a+\frac{1}{4}$, $2a+\frac{1}{8}$, $\ldots$, approaches $2a$ as limit. Accordingly, if $\phi(x)$ assumes the form $\dfrac{0}{0}$ for $x=a$, the value assigned to $\phi(a)$ is the limit value which the sequence of fraction-values approaches as x approaches a through any sequence of x-values for each of which $\phi(x)$ has a definite value. The fraction $\phi(x)$ may be such that as x approaches a, $f(x)$ approaches a definite value other than zero and that $F(x)$ approaches zero. Such a fraction is $\dfrac{x-a+4}{x-a}$. In such case the fraction-value obviously becomes larger and larger, surpassing every prescribed number, a fact commonly expressed by saying that as x approaches a, $\phi(x)$ approaches positive or negative infinity (∞ or $-\infty$) according as the numbers in the fraction sequence are positive or negative. If, as x approaches a, both $f(x)$ and $F(x)$ approach ∞, then, for $x=a$, $\phi(x)$ assumes the indeterminate form $\dfrac{\infty}{\infty}$. But it may be made to take the form $\dfrac{0}{0}$, since $f(x) \div F(x)=(1 \div F(x)) \div (1 \div f(x))$ Other indeterminate forms also reducible to the form $\dfrac{0}{0}$, are $0.\infty$, $\infty.0$, $\infty-\infty$, ∞°, 0^{∞}. For further treatment see CALCULUS.

The boundary of what is or should be called elementary algebra is ill defined alike in theory and in practice, and beside the topics dealt with in this article other subjects are briefly treated in some of the elementary text-books. Of such additional subjects, the more important, as *chance* or *probability*, the *complex variable*, and *theory of numbers*, *series*, and others, are subjects of special articles in this work. Relatively meager, merely introductory, text-books of algebra are sometimes quite absurdly described in their titles as «complete,» and others that might be called advanced are improperly characterized as «higher.» The better usage has appropriated the term higher algebra to the doctrine of invariants and covariants (q.v.).

Bibliography.—Text-books of elementary algebra, good, bad, and indifferent, are very numerous. The most scientific work on the subject is that by Weber and Wellstein: 'Elementare Algebra und Analysis.' The most comprehensive elementary English text-book is Chrystal's 'Algebra,' 2 vols.

CASSIUS J. KEYSER,
Professor of Mathematics, Columbia University.

Algebra, History of the Elements of. Taking the definition of algebra as given in the article under that title (q.v.), the history of the subject goes back to the early Egyptians. In a certain hieratic papyrus now in the British Museum, copied by one Ahmes (*Aāhmesu*, the moon-born), about 1700 B.C., from a work written some centuries earlier, several traces of algebra appear. There are symbols for addition, subtraction, and equality, and eleven examples of linear equations with one unknown quantity are given. The unknown quantity is called *hau*, or heap, the first example involving an equation being "Heap, its seventh, its whole, it makes nineteen" that is, $\frac{x}{7}+x=19$. A number of applied problems are also given, and Ahmes shows some familiarity with arithmetic and geometric progressions. Such was the stagnation of the later Egyptians, however, that algebra never advanced beyond this point, on the banks of the Nile, at least until Greek influence established the famous school of Alexandria.

The Greek mind turned to the science of form rather than to that of number (see GEOMETRY, HISTORY OF THE ELEMENTS OF), and consequently but few evidences of algebra are found in Greece during the golden age of philosophy. Whenever a need for algebra is met it is always for the solution of some geometric problem, and whenever a solution is effected it is usually by some device involving geometry. One of the earliest evidences of an algebraic symbolism is seen in a problem of Aristotle's, in which he represents quantities by means of letters, letting **A** stand for the moving force, **B** for that by which it is moved, **Γ** for the distance, **Δ** for the time, and so on. About the same time Hippocrates (q.v.) called the square of a number **δύναμις** (power), from which the Latins derived the name *potentia*, which appears in our language as *power*. Euclid (q.v.), c. 300 B.C., proved geometrically certain fundamental laws of algebra, such as $a(b+c)=ab+ac$, $(a+b)^2=a^2+2ab+b^2$, $(a-b)^2=a^2-2ab+b^2$, and $(a+b)(a-b)=a^2-b^2$. The equation of the second degree was also known to the Greeks, and they were able to solve the general case by the aid of proportion. Archimedes (q.v.) is even said to have solved one case of the cubic, and he undoubtedly knew a considerable amount about series.

It was not, however, until the time of Diophantus (q.v.), c. 300 A.D., that Greek algebra attained any standing as a separate science. This great mathematical genius improved the symbolism, divorced the subject from geometry, and created the ancient science of indeterminate equations, a science called in his honor «Diophantine Analysis.»

For reasons above suggested, algebra flourished more naturally in the Orient than in Greece. The first Hindu algebraist of any importance was Aryabhata, who was born at Pataliputra, on the Upper Ganges, in 476 A.D. Part of his «Aryabhattiyam» is devoted to algebra, and covers the fundamental operations, rules for

square and cube roots, progressions, permutations, equations of the first and second degrees with one unknown quantity, and some treatment of indeterminate equations. Aryabhata differs from Diophantus in that he considers algebra from a broader standpoint, treating it rather as a theory of elementary functions than as the science of a particular form of the equation.

The next great algebraist in the East was Al Khowarazmi (q.v.), c. 800 A.D., so called from his birthplace, Kharazm, the territory of the modern Khiva. With him algebra takes a still different meaning. It is no longer the theory of indeterminate equations of Diophantus, nor is it chiefly the theory of elementary functions of Aryabhata, but it becomes primarily the general theory of equations. Indeed the title of his work 'ilm al-jabr wa' l muqābalah,' means the science of redintegration and equation, a title from which only the words *al-jabr* have survived, giving the accidental name of *algebra* to the subject. Al Khowarazmi solved three types of the quadratic, in modern symbolism $x^2 + ax = b$, $x^2 - ax = b$, $x^2 + b = ax$, thus showing his inability to generalize, a failing with all writers before the 17th century.

It was two centuries before another writer of prominence appeared. About 1010 A.D., Al Karchi, like Al Khowarazmi of the Bagdad school, wrote a treatise in which he shows familiarity with the works of his predecessors rather than great genius himself. Like many of the older writers, he gives attention to those rules for approximating roots, so necessary before the time of decimal fractions. Stated in modern symbolism his rule for square root is $\sqrt{a} = w + \frac{a - w^2}{2w + 1}$; that is, $\sqrt{10} = 3 + \frac{10 - 9}{6 + 1} = 3\frac{1}{7}$, whence $\sqrt{10}$ was often used for π. He also gives the rule $\sqrt{a + b \pm \sqrt{4ab}} = \sqrt{a} \pm \sqrt{b}$, and a rule for Σn^3.

In the 12th century two Oriental writers of prominence appear, Omar Khayyam (q.v.) the Persian, who died in 1123, and Bhaskara the Hindu, who was born in 1114. Omar solved one case of the cubic, and was the first to treat equations above the second degree in a systematic manner. The binomial theorem with positive integral exponents was also known to him. His algebra, published in Paris both in Arabic and in French, made Omar known in the West as an algebraist some time before FitzGerald made him celebrated as a poet.

Bhaskara wrote on both arithmetic and algebra, and his work has long been known in Europe through Colebrook's English translation. Among the features of his algebra is the statement that $\frac{a}{o} = \infty$, and the solution of the quadratic by the reduction of $ax^2 + bx + c = o$ to the form $(2ax + b)^2 = -4ac + b^2$, a device known in England as the Hindu Method.

The rise of modern elementary algebra took place in Italy in the 16th century. It was at this time that the cubic was solved by Tartaglia (q.v.), the publication being made by Cardan (q.v.) in his *Ars Magna* in 1545. The solution of the quartic soon followed, after which the quintic occupied the attention of algebraists until its solution was proved to be impossible by the operations of elementary algebra, in the 19th century. A common name for algebra at this time was "L'arte maggiore" (the greater art, whence the Latin title of Cardan's treatise), arithmetic being called by contrast "L'arte menore" (the lesser art). The unknown quantity was called, in Latin, *res*, whence the Italian translation *cosa* (thing). On this account the science was called the *Coss* in the early German schools, and the name "Cossic Art" was not uncommon among the English writers of about 1600. The mere processes and solutions of elementary algebra were fairly perfected by the close of the 16th century, and little besides the symbolism was needed to make the subject what it is to-day.

The title of Father of modern elementary algebra is frequently given to Vieta (q.v.). He was the first to devise a systematic and fairly satisfactory scheme of literal notation, using vowels for the unknown quantities and consonants for the knowns. For example, he used *A* where we use x, *Aq* (*A quadratus*) for our x^2, *Ac* for x^3, *Aqq* for x^4, and so on. He also recognized that a letter may represent both a positive and a negative number, and both an integer and a fraction, a generalization not recognized by his predecessors, and one that was perfected later by Descartes. Vieta was also the first to recognize the advantage of making the second member zero in considering an equation. His work greatly influenced the English algebra as set forth by Harriot (q.v.), who acknowledged his indebtedness to him. Mention should also be made of the work of Clavius, who did much to meet the demand for a usable text-book at this period.

The final touch was put upon the elementary science by Descartes (q.v.), who suggested and used our modern literal notation, and who perfected the generalizations begun by Vieta. His introduction of the graphic treatment of equations not only revolutionized mathematics in general, but materially assisted in the understanding of the elements.

Since Descartes's time there have been certain improvements in the symbolism of elementary algebra, the theory of approximate solutions of numerical higher equations has been created, chiefly through the efforts of Newton, Euler, and Horner (qq.v.), the binomial theorem has been generalized for negative and fractional exponents, principally by the labors of Newton, the theory and the symbolism of determinants (q.v.) have been developed, the various number systems met in algebra (notably the complex number) have been placed upon a scientific basis, and in general the foundation theories of the science have been greatly strengthened.

Professor of Mathematics, Teachers College, Columbia University, New York.

Algeciras, or **Algesiras,** a seaport of Spain, on the west side of the Bay of Gibraltar, and 7 m. N.W. of Europa Point. The old town, once possessed of great strength, but now in

ruins, stood on the Isla Verde; the modern town stands on the mainland, on an acclivity rising rapidly from the shore, and though unwalled is defended by a fort. A brisk coasting-trade is carried on by the inhabitants. Near Algeciras were fought two naval engagements in July, 1801. In the first the English admiral Saumarez failed in an attack on the French fleet, which was strongly posted in the bay under the protection of the batteries on shore (6 July), but in the second he defeated the combined French and Spanish fleets (12 July). Pop. 13,000.

Alger, Cyrus, an American inventor: b. West Bridgewater, Mass., 11 Nov. 1781; d. Boston, 4 Feb. 1856. He learned the iron foundry business, and in 1809 established himself in South Boston, where he soon made himself widely known by the excellence of the ordnance he manufactured. He supplied the United States government with a large quantity of cannon-balls during the War of 1812; produced the first gun ever rifled in America, as well as the first perfect bronze cannon; and supervised the casting of a mortar which was the largest gun of cast-iron that had then been made in the United States. Subsequently he made improvements in the construction of time fuses for bomb-shells and grenades; patented a method of making cast-iron chilled rolls; and was the original designer of the cylinder stove.

Alger, Horatio, an American writer of juvenile books: b. Revere, Mass., 13 Jan. 1834; d. Natick, Mass., 18 July 1899. He graduated at Harvard in 1852, settled in New York in 1866, and became interested in the condition of self-supporting boys, described in his series of more than 50 books, including 'Ragged Dick,' 'Tattered Tom,' 'Luck and Pluck,' which became very popular. Other works: 'Nothing to Do: A Tilt at Our Best Society,' a poem (1857); 'Helen Ford,' a novel (1860); a series of juvenile biographies of Webster, Lincoln, Garfield, etc.; and 'The Young Salesman' (1896).

Alger, Russell Alexander, an American merchant, capitalist, and politician: b. Lafayette, O., 27 Feb. 1836. He served in the Civil War, rising from a captaincy to the rank of brevet major-general of volunteers. He acquired a large fortune in western enterprises, particularly the lumber business. He was governor of Michigan from 1885 to 1887; a candidate for the Republican presidential nomination in 1888; commander-in-chief of the Grand Army of the Republic (1889–90); and became secretary of war in President McKinley's cabinet in 1897. Almost from the beginning of the Spanish-American war of 1898 he was the object of much public censure for alleged shortcomings in the various bureaus in his department, and this pressure became so strong and widespread that he resigned his office in 1899 after an investigation committee had exonerated him. In 1901 he published 'The Spanish-American War.'

Alger, William Rounseville, Unitarian clergyman: b. Freetown, Mass., 30 Dec. 1822; d. Boston, Mass., 7 Feb. 1905. Graduated at Harvard Theological School 1847; filled pastorates in Roxbury, Mass., Boston; New York, Denver, Chicago, Portland, Me. Works: 'Poetry of the Orient' (1856); 'Critical History of the Doctrine of a Future Life' (1861); 'Genius of Solitude' (1861); 'Friendships of Women' (1867); 'Life of Edwin Forrest' (2 vols. 1878); 'Symbolic History of the Cross' (1881).

Alge'ria, a French colony in north Africa, having on the north the Mediterranean, on the east Tunis, on the west Morocco, and on the south (where the boundary is ill-defined) the Desert of Sahara; area, 122,878 sq. m., or including the Algerian Sahara, 257,000. The country is divided into three departments — Algiers, Oran, and Constantine. The coast-line is about 550 m. in length, steep and rocky, and though the indentations are numerous the harbors are much exposed to the north wind. The country is traversed by the Atlas Mountains, two chains of which — the Great Atlas, bordering on the Sahara, and the Little, or Maritime Atlas, between it and the sea — run parallel to the coast, the former attaining a height of 7,000 feet. The intervals are filled with lower ranges, and numerous transverse ranges connect the principal ones and run from them to the coast, forming elevated table-lands and enclosed valleys. The rivers are numerous, but many of them are mere torrents rising in the mountains near the coast. The Shelif is much the largest. Some of the rivers are largely used for irrigation, and artesian wells have been sunk in some places for the same purpose. There are, both on the coast and in the interior, extensive salt lakes or marshes (*shotts*), which dry up to a great extent in summer. The country bordering on the coast, called the Tell, is generally hilly, with fertile valleys; in some places a flat and fertile plain extends between the hills and the sea. In the east there are *shotts* that sink below the sea-level, and into these it has been proposed to introduce the waters of the Mediterranean. The climate varies considerably according to elevation and local peculiarities. There are three seasons: winter from November to February, spring from March to June, and summer from July to October. The summer is very hot and dry. In many parts of the coast the temperature is moderate and the climate so healthy that Algeria is now a winter resort for invalids.

The chief products of cultivation are wheat, barley, and oats, tobacco, cotton, wine, silk, and dates. Early vegetables, especially potatoes and pease, are exported to France and England. A fibre called *alfa*, a variety of esparto, which grows wild on the high plateaus, is exported in large quantities. Cork is also exported. There are valuable forests, in which grow various sorts of pines and oaks, ash, cedar, myrtle, pistachio-nut, mastic, carob, etc. The Australian *Eucalyptus globulus* (a gum-tree) has been successfully introduced. Agriculture often suffers much from the ravages of locusts. Among wild animals are the lion, panther, hyæna, and jackal; the domestic quadrupeds include the horse, the mule, cattle, sheep, and pigs (introduced by the French). Algeria possesses valuable minerals, including iron, copper, lead, sulphur, zinc, antimony, marble (white and red), phosphate, and lithographic stone.

The trade of Algeria has greatly increased under French rule, France, Spain, and England being the countries with which it is principally carried on, and three fourths of the whole being with France. The exports (besides those men-

tioned above) are olive oil, raw hides, wood, wool, tobacco, oranges, etc.; the imports, manufactured goods, wines, spirits, coffee, etc. The manufacturing industries are unimportant, and include morocco leather, carpets, muslins, and silks. French money, weights, and measures are generally used. The chief towns are Algiers, Oran, Constantine, Bona, and Tlemcen. There are about 2,000 miles of railways opened; there is also a considerable network of telegraph lines.

The two principal native races inhabiting Algeria are Arabs and Berbers. The former are mostly nomads, dwelling in tents and wandering from place to place, though a large number of them are settled in the Tell, where they carry on agriculture and have formed numerous villages. The Berbers, here called Kabyles, are the original inhabitants of the territory and still form a considerable part of the population. They speak the Berber language, but use Arabic characters in writing. The Jews form a small but influential part of the population. Various other races also exist. Except the Jews all the native races are Mohammedans. There are now a considerable number of French and other colonists, provision being made for granting them concessions of land on certain conditions. There are over 260,000 colonists of French origin in Algeria, and over 200,000 colonists natives of other European countries (chiefly Spaniards and Italians). Algeria is governed by a governor-general, who is assisted by a council appointed by the French government. The settled portion of the country, in the three departments of Algiers, Constantine, and Oran, is treated much as if it were a part of France, and each department sends two deputies and one senator to the French chambers. The rest of the territory is under military rule. The colony costs France a considerable sum every year. Pop. (1902) estimated about 4,500,000.

Industries.— The wine business at the present day constitutes the largest industry in Algeria. Until very recently it had been going up by leaps and bounds, many large fortunes having been made. During 1900 and 1901, however, the price of wine steadily decreased on account of the abnormal yield in France, and great losses were consequently incurred by those who were forced to dispose of their vintage. In 1902, the crops in France having been greatly damaged by late frosts, wet, and severe hailstorms, the wine-growers partially recouped their losses. The amount of wine exported from Algeria during 1897 was 781,558 gallons; in 1898, 796,049 gallons; in 1899, 945,879 gallons; and in 1900, 549,131 gallons. The other principal products are alfa, cereals, cork, vegetable hair, locust beans, olive oil, fruits, and vegetables, and Italian pastes. The area which alfa occupies in the three departments of Algeria is estimated at more than 12,000,000 acres. The principal district, called the « Alfa Sea,» is 210 miles by 95 miles and is bounded on the N. by the Tell, on the W. by Morocco, on the S. by the mountains of Ksowes, and on the E. by the Hodna. The producing area is much greater than that actually cut; nevertheless, in order to prevent the loss which would result from bad working, the governor-general issued an order in 1888 limiting the cutting, sale, and export of alfa. The average production of an acre of alfa is estimated at 8 cwt. after drying and sorting. In 1900 Algeria exported 1,650,235 cwt. of wheat, 1,188,153 cwt. of oats, 1,773,509 cwt. of barley, and 27,496 cwt. of maize. The barley is much in demand in Europe for malting purposes. Algeria produces excellent hard wheat, giving a flour rich in gluten, and consequently very good for the manufacture of Italian pastes and semolina. This industry is annually increasing; the existing works are enlarging and improving their machinery, modern methods of shop management are being introduced, and the output of the various establishments to-day rivals that of France and other countries.

Algerine War. See Barbary Powers, U. S. Treaties and Wars With the.

Alghero, or **Algheri**, a fortified town and seaport on the W. side of the island of Sardinia, in the province of Sassari, and 17 m. S.W. of the town of that name. The port is not good, but 7 m. W. of it is Porto Conte, the best harbor in the island. The town is the seat of a bishop and possesses a handsome cathedral. The inhabitants are mainly employed in wine-growing and coral-fishing. Pop. 10,500.

Algiers (French, *Alger*), a city and seaport on the Mediterranean, capital of the French colony of Algeria, is situated on the W. side of the Bay of Algiers. It stands on the slope of a hill facing the sea, from which its array of white houses, rising in the form of an amphitheatre, presents an imposing appearance. The old town, which is the higher, has an Oriental aspect. Its crowning point is the Casbah, or ancient fortress of the deys, about 500 feet above the sea. Its streets are narrow, crooked, and dirty. The houses are strong, prison-like edifices, with iron-grated slits for windows, looking into central quadrangles entered by a low doorway. The modern town, which occupies the lower slope and spreads along the shore, is handsomely built, with broad streets adorned with arcades and having elegant squares. It contains the government buildings, the barracks, the commercial warehouses, the residences of the governor-general and the government officials, and the superior courts of justice. The Place du Gouvernement and the Place Bresson here are the two chief squares of the city. The fine Boulevard de la République runs along the sea-front, overlooking the bay and harbor. Algiers is the seat of an archbishop. It has a cathedral and a number of churches (one of them being an English church) and mosques. There are schools of law, medicine, science, and letters, and a lyceum; also a library and museum. It is defended by sea-batteries and other works. The French have been at great expense in improving the port and providing docks. Pop. about 100,000.

Algoa Bay, a bay on the S.E. coast of Cape Colony, Africa; about 420 m. E. of the Cape of Good Hope. At its entrance, formed by Cape Woody on the N.E. and Cape Recife on the S.W., it has a width of 33 miles. Its shelter is very valuable, as there is no other refuge for ships during the N.W. gales. The

usual anchorage is off Port Elizabeth, at the mouth of the Baakens, where there is now a large and increasing trade.

Algol', a star in the constellation Perseus (head of Medusa), remarkable as a variable star, changing in brightness from the second to the fourth magnitude.

Algo'ma, a district of Canada, on the N. side of Lake Superior, forming the N. W. portion of Ontario, rich in silver, copper, iron, etc.

Algona, Iowa, city and county-seat of Kossuth County, on the Iowa Cent., Chicago & N. W., and Chicago, M. & St. P. R.R.'s about 123 m. N. by W. of Des Moines, on a branch of the Des Moines River. The city has four banks, handsome public buildings, and flourishing manufactures of foundry and machine-shop products, wooden-ware, bricks and tiles. Pop. 3,000.

Algonkian System, the name given in the United States to a great series of rocks that succeeds the basal system of the Archæan and is overlaid by the strata of the Palæozic system. The rocks of the Algonkian system are developed on an enormous scale in the Lake Superior region, where they comprise limestones, sandstones, quartzites, shales, slates, and schists, all more or less disturbed and bearing evidence of having been subjected to metamorphism. They also include dikes and beds of igneous rocks, and great copper and iron ore deposits, which are among the richest in the world. A few fossil remains have been found, but little is known as to the life conditions during the Algonkian period.

Algonquian, or **Algonkian Stock**, a North American group once comprising forty or more separate languages, and embracing a larger area than any other on the continent, stretching in a solid block from Labrador to the Rockies and from Hudson's Bay to Pamlico Sound and the Cumberland River at least, except the enclaves of Iroquois in and around New York State, and of Beothukan in Newfoundland. Outlying tribes were the Shawnee or Shawano to the south; and to the west the Cheyenne and Arapahoe, which clove their way through the heart of the Sioux across the Missouri and into the Black Hills region, and later to Colorado and Wyoming, their advance westward being checked by the Shoshone group. They numbered several hundred tribes, or « villages," entirely independent; many in which several such villages were grouped together; and several confederacies of tribes united in a loose bond for mutual aggression or defense, though never with any real central government. The chief confederacies were the Abnaki or Abenaki of Maine and New Brunswick; the Pennacook of New Hampshire, and the adjacent parts of Maine and Massachusetts; the Powhatan of Virginia and Maryland; the Illinois or Illini of that region and adjacent Wisconsin, Iowa, and Missouri; the Siksika (Blackfeet, etc.) of northern Montana and adjacent Canada; the Cheyenne and Arapahoe, already mentioned; and the Sac and Fox, first at the mouth of the Ottawa, then in northern Wisconsin. (See each title.) Of the individual tribes, the most important remaining were the Micmac, Amalecite, Massachuset, Wampanoag, Narraganset, Nipmuc, Pequot, Mohegan, Mohican, Metoac, and Wappinger on the North Atlantic coast; Munsi, Leni-Lenape or Delaware, Shawano, Nanticoke, Conoy, Mattamuskeet, on the South Atlantic coast; Nascapi, Montagnais, Algonquin, Ottawa, Muskegon, Cree, Ojibwa, Misisaga, Miami, Piankishaw, Kickapoo, Pottawotomi, Menomini, in the interior; and Atsina in the West. Tradition places the original home of all these tribes on the North Atlantic coast.

From their being the first to come in contact with the English settlers, and the history of English settlement for two centuries being a steady record of fierce conflict with and bloody reprisals from and on them, more is known of their minor names and those of their great chiefs — Powhatan, Opechancanough, Philip, Pontiac, Tecumseh, Black Hawk, etc.— than of any others except the Iroquois, and their languages are better studied.

Constant wars with the English, French, and Dutch colonists depleted their numbers. Filled at first with the idea of freeing the soil from the whites, they afterward degenerated into mere mercenaries, fighting on either side for revenge or gain. After the War of 1812, in which they took the side of the British, the United States government resolved to send them as far west as possible. After 1840 few of them remained east of the Mississippi. In Canada they were not removed from their homes, but were limited as to territory. War and disease have thinned their number until only about 43,000 remain in the United States, and 38,000 in Canada; there are a few hundred refugees in Mexico.

Algonquin (properly **Algomekin**, « other-siders ») a once powerful Indian tribe along the Ottawa River and Lake Nipissing, Canada. Decimated by the Iroquois, some of them with other Indian waifs took refuge along the Upper Lakes and assumed the name of Ottawas (q.v.), bringing forth the greatest Indian of history, the mighty Pontiac (q.v.); others kept their name and were protected by the French in mission villages. It was French missionaries who discovered almost at their first coming that the Algonquin language was a type common to what is now called the Algonquian stock. The chief body of the remaining tribe numbers nearly 1,000, in villages of Quebec and Ontario; about 250 more are confederated with the Iroquois at Gibson, Ont., and Lake of Two Mountains, Que.

Alhama, a town of Spain, on the Motril; 25 m. S.W. of the town of Granada. This place is celebrated for its warm medicinal (sulphur) baths and drinking-waters, and also for its romantic situation between craggy mountains. The principal bath was a Moorish edifice, the smaller was circular in form and probably a Roman erection. The town was thrown completely into ruins by an earthquake shock in 1884. Washington Irving, in his ‹ Chronicle of Granada,› gives a spirited account of the taking of Alhama, « the key of Granada," from the Moors, by Rodrigo Ponce de Leon, Marquis of Cadiz, in February 1482.

Alhambra (*Kelât-al-hamrah*, the red castle), the citadel of Granada when that city was one of the principal seats of the empire of the Moors in Spain. The wall which surrounded it still stands flanked by many towers, and has a cir-

cuit of 2¼ miles. Within it were included several important buildings, besides dwelling-houses; but the building to which the celebrity of the site is due is the Alcazar, or royal palace of the kings of Granada, seated on the northern brow of a lofty eminence which commands a full view of the city of Granada, and, beyond it, of a charming country, bounded in the distance by a line of hills. It is a place equally interesting to the artist, the antiquarian, and the historian. The erection of the greater part of the present building seems to have occupied almost the whole of the first half of the 14th century. It consists mainly of two oblong rectangular courts, the one (which was seriously damaged, if not ruined, by fire in September 1890), called the court of the Fish-pond or of the Myrtles, 138 by 74 feet, and terminating at its northern end in an apartment 35 feet square, richly ornamented: the other, called the Court of the Lions, 115 by 66 feet, and so named from the white marble fountain in the centre supported by twelve lions. An exact repetition of this court, on two thirds of the scale of the original, was made by Mr. Owen Jones in the Crystal Palace. It is surrounded by an arcade, with small pavilions at each end, consisting of 128 columns supporting arches of the most delicate and elaborate finish, still very perfect and retaining much of their original beauty. From the character of many of the arches in various portions of the palace they are most appropriately called stalactitic. They are formed on a peculiar system with plaster bricks of various forms in a manner universally adopted in the buildings of the Moors. The construction of the arches is remarkable for its simplicity. Over the columns, which are of white marble, and which were probably gilded, are brick piers carrying rough brick arches; above these tiles are placed diagonally, forming diamond-shaped open work, running through the thickness of the walls, and a brest-summer of timber supporting the weight above. To these rough arches are attached the various enrichments, and against the tiles are placed the perforated plaster ornaments which give a singularly light appearance to the arches, and create very beautiful effects from the rays of light cast through the openings on the wall behind them.

Alhambra, The, by Washington Irving. (1832. Revised, enlarged, and rearranged, 1852.) This Spanish Sketch-Book grew out of the experiences and studies of Irving while an actual resident in the old royal palace of the Moors at Granada. Many of the forty sketches have their foundation only in the author's fancy, but others are veritable history.

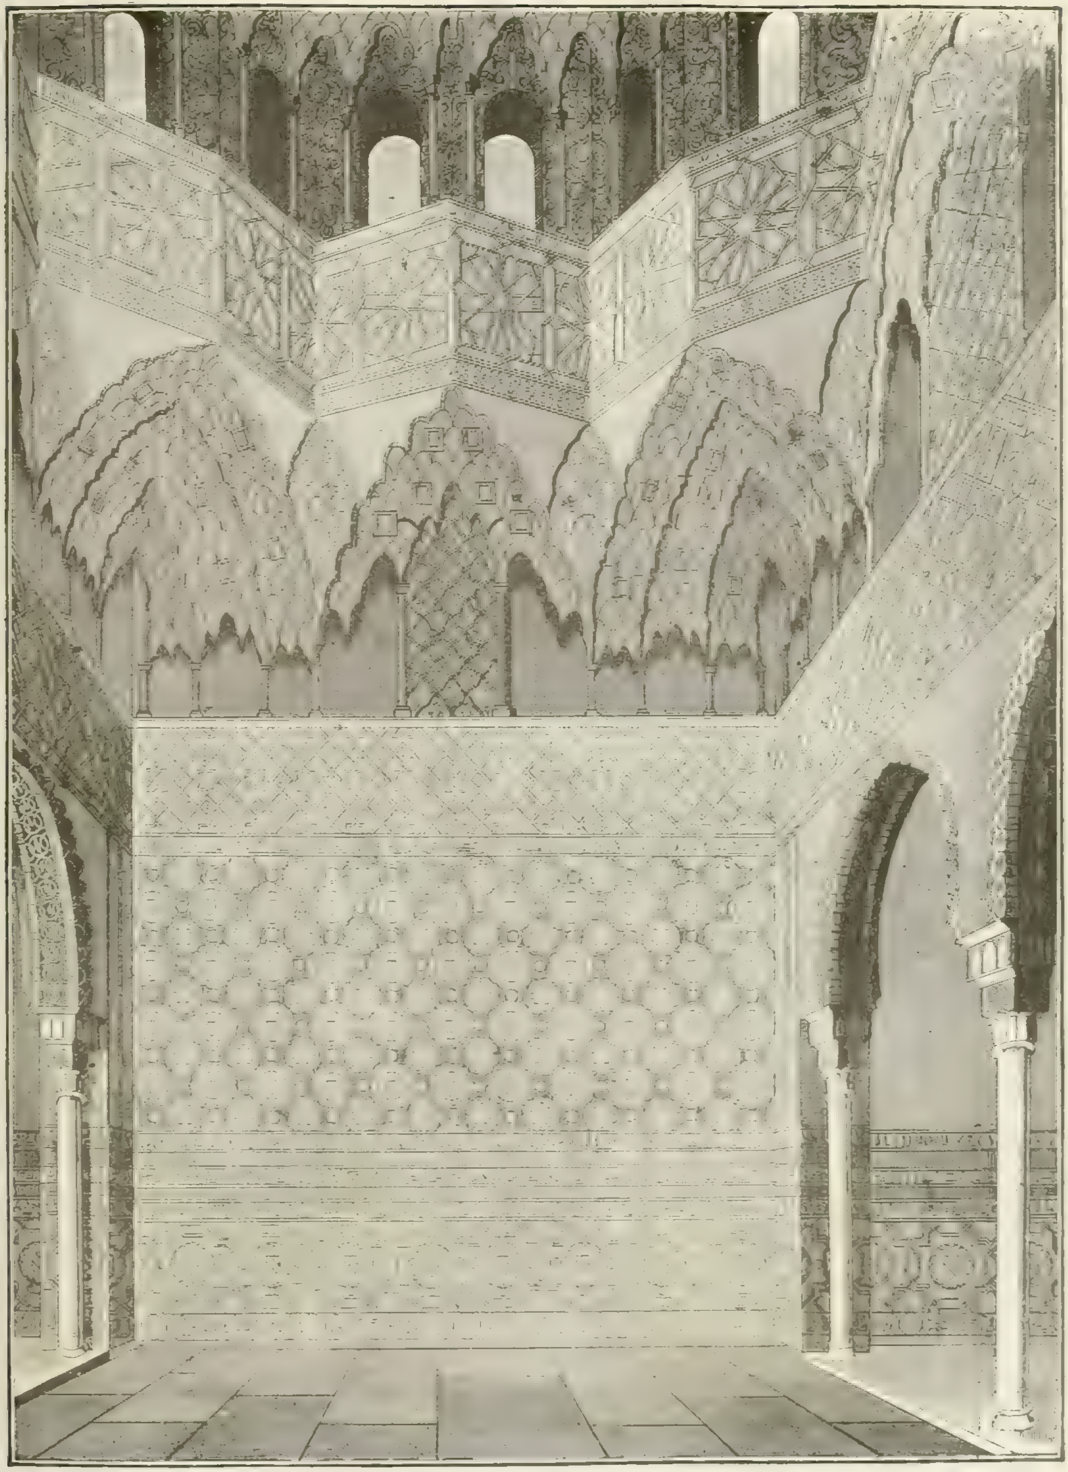
Ali, â'lē, cousin and son-in-law of Mohammed, the first of his converts, and the bravest and most faithful of his adherents; b. 602; d. 661. He married Fatima, the daughter of the prophet, but after the death of Mohammed (632) his claims to the caliphate were set aside in favor successively of Abu-Bekr, Omar, and Othman. On the assassination of Othman, in 656 A.D., he became caliph, and after a series of struggles with his opponents, including Ayesha, widow of Mohammed, finally lost his life by assassination at Kufa. A Mohammedan schism arose after his death, and has produced two sects. One sect, called the Shiites, put Ali on a level with Mohammed, and do not acknowledge the three caliphs who preceded Ali. They are regarded as heretics by the other sect, called Sunnites. The Maxims and Hymns of Ali are yet extant. See CALIPH.

Ali, pasha of Yanina, commonly styled **Ali Pasha,** a bold and able, but ferocious and utterly unscrupulous Albanian, b. 1741, son of an Albanian chief who was deprived of his territories by rapacious neighbors. By his enterprise and success and entire want of scruple he got possession of more than his father had lost, making himself master of a large part of Albania, including Yanina, which the Porte sanctioned his holding, with the title of pasha. As a ruler he displayed excellent qualities, putting an end to brigandage and anarchy, making roads, and encouraging commerce. He extended his sway by subduing the brave Suliotes of Epirus, whom he conquered in 1803 after a three years' war. Aiming at independent sovereignty, he intrigued alternately with England, France, and Russia. Latterly he was almost independent of the Porte, which at length determined to put an end to his power; and in 1820 Sultan Mahmoud pronounced his deposition. Ali resisted several pashas who were sent to carry out this decision, only surrendering at last in 1822 on receiving assurances that life and property should be granted him. Faith was not kept with him, however; he was killed and his head cut off and conveyed to Constantinople, while his treasures were seized by the Porte.

Alias, in law, a term used to indicate the names under which a person who attempts to conceal his true name is ascertained to have passed during the successive stages of his career. An alias writ is a writ issued where one of the same kind has been issued before in the same cause.

Ali Baba, the principal figure in the famous 'Arabian Nights' Entertainments' tale of 'Ali Baba and the Forty Thieves.' He overhears the thieves opening the door of their cavern by the use of the magic words «Open sesame.» He does the same in their absence and appropriates as much of their wealth as he can carry. Cassim, his brother, enters the cave later, but having forgotten the magic word is presently found by the robbers and killed. They make an attempt to slay Ali Baba, but are defeated by the slave Morgiana, who pours boiling oil in the jars in which the robbers are hidden.

Ali Bey, a ruler of Egypt: b. in the Caucasus in 1728, was taken to Cairo and sold as a slave, but having entered the force of the Mamelukes, and attained the first dignity among them, he succeeded in making himself virtually governor of Egypt. He now refused the customary tribute to the Porte and coined money in his own name. In 1769 he took advantage of a war in which the Porte was then engaged with Russia, to endeavor to add Syria and Palestine to his Egyptian dominion, and in this he had almost succeeded when the defection of his own adopted son Mohammed Bey drove him from Egypt. Joining his ally Sheikh Daher in Syria, he still pursued his plans of conquest with remarkable success, till in 1773 he was induced to make the attempt to recover Egypt with insufficient means. In a battle near Cairc



SECTION IN PALACE—Alhambra

his army was completely defeated and he himself taken prisoner, dying a few days afterward either of his wounds or by poison.

Alibi, in law, a plea that the person accused of having committed a crime was elsewhere at the time when the breach of the law occurred. If he substantiate this, he is said to prove an alibi. In Scotland the defendant must give notice of a special defense of alibi, stating where he was when the crime was committed. In England and the United States this notice is not required. If the accused can make it appear that at the time when the crime charged is alleged to have been committed (it being of a nature to require his personal presence) he was in another place, his innocence will be established, because of the obvious impossibility of the same person being in two places at once. This species of defense is constantly resorted to in trials for crime. One of the principal rules in the application of this species of evidence is that the time relied on, and in which the value of the evidence mainly consists, must correspond closely with the time at or during which the offense is proved to have been committed. If, time having been fixed to a particular day, hour, and minute, the person accused can show that at that exact time he was in another place, his innocence is at once made apparent.

Alicante, a seaport of Spain; capital of the province of Alicante; the ancient Lucentum. It is situated at the foot of a cliff 850 feet high, crowned by the fort of Santa Barbara. It has one of the best harbors on the Mediterranean, and carries on a considerable trade, exporting wine, fruit, esparto grass, etc. It was bombarded in 1873 by two vessels sent out by Cartagena insurgents. Prof. Freeman, the English historian, died here in 1892. An American consul has been stationed at Alicante for some years. Pop. (1900) 50,495.

Alicata, or **Licata**, â-lē-kä'tâ, lē-kä'tâ, the most important commercial town on the south coast of Sicily, at the mouth of the Salso, 24 m. E.S.E. of Girgenti, with a considerable trade in sulphur, grain, wine, oil, nuts, almonds, and soda. It occupies the site of the town which the tyrant Phintias of Acrogas erected and named after himself, when Gela was destroyed in 280. Pop. 15,966.

Alice's Adventures in Wonderland, by Lewis Carroll (Charles L. Dodgson). Alice, a bright little girl, is the heroine of the tale and by following an extraordinary rabbit into a rabbit hole, she finds herself in a land where unreal things seem real. Her mistakes at first barely save her from drowning in her own tears; but she presently meets many queer animal friends besides a crusty old Duchess, a mad Hatter, a sleepy Dormouse, and a March Hare, with whom she has strange experiences, and finally they take her to play croquet with the Queen of Hearts. During a trial by jury at the court of the Queen, Alice becomes excited and calls every one there nothing but a pack of cards. As they rise into the air and come flying down upon her, she awakes to find herself on a bank where she had fallen asleep. A sequel to the story is 'Through the Looking-Glass,' (1871).

Alien, any person not legally within the jurisdiction of a country as one of its citizens. By the laws of the United States the children of male citizens, whether born within the country or abroad, are held to be citizens; but all other foreign-born individuals are aliens until made citizens by naturalization. In the United States aliens are nominally prohibited from acquiring title to real estate, but in practice they may own lands subject to proceedings by the State to determine the fact of alienage; and, moreover, in nearly all the States there are special provisions removing such restrictions from resident aliens who are in the course of naturalization. The rights of aliens to hold personal property and carry on trade are the same as those of citizens. In time of war, however, aliens belonging to the country of the enemy cannot make contracts with citizens or resort to the courts except as accorded such privileges by special treaties. In the United States, if an alien dies without making a will and without leaving any known heirs, his estate immediately vests in the State without office found. An alien may sue and be sued; he may be tried for crime, and has a right to labor and to trade. No State can pass a law refusing rights to aliens which are secured by treaty. A law of this kind would be void, for the reason that every treaty made by the authority of the United States is superior to the constitution and laws of any State. Naturalized aliens are subject to political disabilities as follows: They are permanently disqualified for election as President or Vice-President, and cannot become members of the National Senate or House of Representatives until they have been citizens for nine or seven years respectively. In Great Britain there is no discrimination whatever between aliens and subjects as far as property rights are concerned. It is held by British law that the children of aliens born in Great Britain are natural-born subjects. In all Christian countries the tendency of legislation concerning aliens shows increasing liberality, although it is still the policy of the Latin nations, in their colonies, to limit materially the trade advantages of foreigners.

Alien and Sedition Acts, in American political history, four acts passed by the Federalist party in Congress in the summer of 1798, under John Adams, which were the immediate cause of the first nullification proceedings in the South (see KENTUCKY RESOLUTIONS; NULLIFICATION; VIRGINIA RESOLUTIONS), and one of the causes which alienated enough votes from the Federalists to drive them out of power sooner than was inevitable. (For the genesis of the alien acts see also AMERICAN PARTY.) The embittered exiles who flocked here from 1790 on were doubly obnoxious to the Federalists: both as scurrilously offensive journalists, oftentimes, and as hostile to all attempts to punish France for her wanton aggressions on American commerce. In 1797 the House was Republican, the Senate Federalist; the latter attempted to pass measures for defense against France, which the former steadily voted down. At length, in 1798, the publication of the "X. Y. Z." correspondence, showing the rottenness of the French Directory, shamed the defenders of France and incensed the moderates into supporting the Federalists: who, having now a majority in both houses, first enacted three laws concerning aliens: (1) 18 June, making the residence be-

fore naturalization fourteen years instead of five, and the term after declaration of intentions five instead of three; alien enemies not to be allowed naturalization; registration of all aliens on arrival, under penalties, and entry on such register the only proof admitted on applying for naturalization. (2) 25 June, empowering the President for two years to order out of the country any aliens he thought dangerous or engaged in conspiracies. (3) 6 July, legalizing the apprehension or deportation of all resident aliens when war was declared against the United States. These acts were denounced by the Republicans on three grounds, two of State rights and one general: as invading the Constitutional rights of the States to permit such immigration as they chose up to 1808 (really intended to apply only to slaves); that it assumed national powers over persons under the jurisdiction of their States; and that it violated the right of trial by jury. It was on these points that Jefferson and Madison drew up the Kentucky and Virginia legislative resolutions; the former of which, on its repetition in 1799, named nullification as the proper remedy. Second, on 26 June, Lloyd of Maryland introduced a bill (1) declaring France an enemy of the United States, and any one who should uphold her or give her aid or comfort guilty of high treason; (2) defining treason; (3) imposing $5,000 fine and six months' to five years' imprisonment on any one conspiring to oppose or impede United States measures, intimidate United States officers, stir up insurrection, etc.; (4) imposing a fine of not over $2,000 and imprisonment for not over two years for any utterance or writing tending to justify France, or to defame United States officials as hostile to popular liberties, etc. It passed the Senate by a heavy majority; the House made important changes in it and passed the altered bill by a scratch. These changes were: (1) Canceling the first two sections altogether; (2) substituting for the fourth, the publishing or printing any false, scandalous, or malicious writings to bring the Government, Congress, or President into contempt or disrepute, excite popular hostility to them, incite resistance to United States laws or encourage hostile designs against the United States, etc. To these, which gave Federal judges power to make any opposition to the ruling party a felony, Bayard of Delaware got two clauses added which drew their teeth: the first making the truth a good defense and juries the judges of the fact; the second restricting the term of operation to 4 March 1801 — that is, till a new administration came in, so that it should expire with the Federalists if they went out, and the Republicans thus lose the *éclat* of repealing it. It would naturally be supposed that the Alien Acts, which affected only a few foreigners and no internal liberties, and which as a fact remained entirely unenforced, would have caused little commotion in the Republican party; and that the Sedition Act, which struck at all liberty of free speech or publication, and was contrary to the very basis of free government, and under which at least six prosecutions and most scandalous performances of one Federal judge took place, would have provoked almost a civil war. The facts are an instructive historical lesson against transferring the ideas of one age to another. The Republicans disliked the use of prosecutions under the Sedition Act as a party weapon, and resented Judge Chase's partisan decisions; but it was only as directed against themselves, not as against civil liberty, that they reprobated it,— neither party had attained to that ideal,— and their chief rhetoric and defiance was directed against the harmless acts which tried to prevent their supporting France. It was in crystallizing the spirit of State resistance to national power that the acts have their main importance.

Alienation of Estates, comprises any method whereby estates are voluntarily resigned by one and accepted by another, whether that be effected by sale, gift, marriage settlement, devise, or other transmission of property by the mutual consent of the parties. 2 Bl. Com., § 287; 55 N. J. L. 417. The term alienation is particularly applied to absolute conveyances of real property. 1 N. Y. 290, 294.

Alienations by deed may be by conveyances at common law; which are either original or primary, being those by means of which the benefit or estate is created or first arises; or derivative or secondary conveyances, being those by which the benefit or estate originally created is enlarged, restrained, transferred, or extinguished; or they may be by conveyances under the statute of uses. The original conveyances are the following: feoffment, gift, grant, lease, exchange, partition. The derivative are release, confirmation, surrender, assignment, defeasance. Those deriving their force from the statute of uses are covenants to stand seized to uses, bargain and sale, lease and release, deeds to lead or declare the uses of other more direct conveyances, deeds of revocation of uses. 2 Bl. Com. ch. 20; 2 Washb. Real Prop. 600.

Alienist. See PSYCHIATRY.

Ali Ferrough Bey, Turkish diplomatist: b. Constantinople, 1865. After serving as secretary of embassy at Paris, London, and Bucharest, as well as councilor of embassy at St. Petersburg, he was promoted to the post of minister-plenipotentiary and envoy-extraordinary to the United States. Besides histories of Arabia and Turkey he has published 'Public and Private International Law.'

Aligarh, or **Alighur,** a town in India, in the Northwest Provinces, in the executive district of the same name, 53 m. N. of Agra. Aligarh is merely a fortress, the town being Coel, distant about two miles and connected with Aligarh by a beautiful avenue. It was formerly of importance and was more recently one of Dowlet Rao Sindia's principal depots for military stores. The fort is square, with round bastions, ditch, and glacis, and a single entrance, protected by a strong ravelin. It was taken in 1803 by Lord Lake, Sindia's commander, Perron (a Frenchman) having previously surrendered, and the whole district was then added to the British possessions. Since that time the fort has been much improved, and the town made the station of a civil and judicial establishment. Pop. of Coel (1901) 70,127.

Aliment. See FOOD; NUTRITION.

Alimentary System, or **Gastro-intestinal System,** is the collection of organs in animals that is chiefly concerned in the processes of digestion and nutrition. It is, in man, a highly complicated tube of some thirty or more feet in length, beginning at the mouth, then the

pharynx, the œsophagus leading into the stomach, which organ is a dilated and pouch-like portion of the tube. From the stomach the tube is narrowed into the small intestine, there being some twenty to twenty-five feet of this, divided into three parts, the duodenum, the jejunum, and the ileum. These three parts are distinguished the one from the other by means of their minute histological structure. At the end of the ileum the tube once more dilates, a pouch is formed, the appendix vermiformis being situated here, and the large intestine or colon begins. This passes up the right side of the abdomen, constituting the ascending colon; crosses over under the liver high up in the abdomen, about on the level of the umbilicus, the transverse colon; then descends on the left side, to turn at the lower iliac region abruptly backward and into the centre of the body to form the short rectum. The tube terminates at the anus, guarded by two circular muscles known as the sphincters. The number of accessory glands and organs that empty their secretions into the intestinal system is very great. The most important are the salivary glands in the mouth, the digestive glands of the stomach, the liver and pancreas, the secretions of which enter by a common duct just below the stomach, and the intestinal glands. Mucous glands are found throughout the entire length of the intestinal system.

The structure of the different portions of the tube is similar, but variations in function produce slight modifications, especially in the muscular coats. In general there is a layer of mucous membrane on the interior of the canal; this is surrounded by a connective-tissue supporting framework, and is further strengthened by a varying amount of unstriped muscular tissue. The details of structure will be considered in the descriptions of the several organs. (See INTESTINE; STOMACH.) The work of the alimentary system in the complicated chemical processes of digestion is more fully described in various other articles. See DIGESTION; METABOLISM; NUTRITION.

Alimony, in law, the allowance, awarded out of her husband's estate, to which a wife is entitled on separation or divorce. Jurisdiction in this matter in England rested with the ecclesiastical court until 1857, when it was conferred upon a court of divorce. In the United States it is vested in the courts of equity. Alimony may be granted by the court during litigation, in which case it is known as *pendente lite* (during the suit); or at the conclusion of the suit, when it is called permanent. The former enables the wife to pursue the litigation, whether proceedings have been brought by or against her. The amount granted lies within the discretion of the court and depends upon a variety of considerations, and is governed by no fixed rules. The ability of the husband to pay is of most importance in determining the amount, and in estimating his ability his entire income will be taken into consideration, whether derived from his property or his personal exertions. So far as any general rule can be drawn from the decisions and practice of the courts, the proportion of the joint income to be awarded for permanent alimony is said to range from one half to one third, while in case of alimony pending suit it is not usual to allow more than one fifth, and usually a smaller proportion will be allowed out of a large estate than out of a small one. Permanent alimony is a periodical allowance awarded to the wife if the termination of the suit is favorable to her. By a writ of *ne exeat* (let him not depart) the court can prevent the husband from leaving the State without leaving sufficient security for payment. The writ of *ne exeat* has been expressly abolished in many of the States of the Union, but its place has been filled in almost every instance by a similar procedure. In New York a system of arrest and bail has been substituted for the writ. If the husband should remove to another State the wife can enforce her claim in the Federal courts. See MARRIAGE AND DIVORCE.

Alis, Hippolyte Percher, al-ē, ip-o-lēt pär shā, French novelist and journalist: b. Couleuvre, 7 Oct. 1857. Besides journalistic work, he has written several «naturalistic» novels, including ‹Hara-Kiri› (1882); ‹A Daughter of the Soil› (1885); ‹Some Foolish People› (1889).

Alishan, Leo M., äl-ē-shan', Armenian poet and historian: b. Constantinople, 30 July 1820; studied in Venice, took orders there 1840, was given a chair in the College Raphael, and made its director 1848; head of the Armenian college in Paris 1858, director of St. Lazare in Venice 1865. Armenians regard him as their leading poet. His complete poems were published 1857–67. He issued ‹Popular Songs of the Armenians› (1867); ‹Historical Monographs› (1870); ‹History and Geography of Armenia› (1885), seized and suppressed by the Turkish authorities.

Alisma'ceæ, the water-plantain family. *Sagittaria* (arrowhead). See ARROWHEAD; WATER PLANTAIN.

Al'ison, Rev. Archibald, Scottish theologian and writer on æsthetics: b. Edinburgh, 1757; d. there 1839. Studied at Glasgow and Oxford, entered the English Church, and (1800) settled as the minister of an Episcopal chapel at Edinburgh. He published two volumes of sermons, and a work entitled ‹Essays on the Nature and Principles of Taste› (1790), in which he maintains that the beauty of material objects depends upon the associations connected with them.

Al'ison, Sir Archibald, Scottish lawyer and writer of history, son of the above: b. Shropshire, 1792; d. near Glasgow, 1867. He was educated at Edinburgh University, and in 1814 was admitted to the Scottish bar. After several years passed in Continental travel he was appointed advocate-depute, which post he held till 1830. In 1832 he published ‹Principles of the Criminal Law of Scotland,› and in 1833 ‹The Practice of the Criminal Law.› Was appointed sheriff of Lanarkshire in 1834, and retained this post till his death. He was made a baronet in 1852. His chief work, ‹The History of Europe, from 1789 to 1815,› was first issued in 10 vols. 1833–42, the narrative being subsequently brought down to 1852, the beginning of the second French empire.

Alison, Sir Archibald, Jr., Scottish general: b. Edinburgh, 21 Jan. 1826. He was a son of the preceding and was educated at Glasgow and Edinburgh, and after entering the English army served in the Crimea and India.

He distinguished himself while second in command of the Ashantee expedition, 1873–74, and also in the war in Egypt in 1882, becoming lieutenant-general in that year. He retired in 1893.

Aliza'rin (from *alizari*, the commercial name of madder in the East), a substance having the formula $C_{14}H_6O_2.(OH)_2$, formerly obtained from the root of the madder (*Rubia tinctoria*), but now artificially produced from coal-tar and the refuse from the distillation of crude petroleum. It is used as a dye, for producing the color known as "turkey red." Alizarin is of interest to the chemist not only on account of its industrial importance, but also because it was the first vegetable coloring matter to be produced artificially; and the year 1868, in which its synthesis was effected by W. H. Perkin, therefore marks the beginning of a new era in industrial chemistry. In the manufacture of alizarin, anthracene ($C_{14}H_{10}$) is first prepared from coal-tar, and by oxidation (which it readily undergoes under the influence of potassium bichromate or other oxidizing agent) is transformed into anthraquinone, $C_{14}H_8O_2$. The next step is to sulphonate the substance so formed. Anthraquinone is remarkably stable toward sulphuric acid, but combination can be effected by strongly heating a mixture of the two, and a solution of mono- and disulphonic acids of anthraquinone is the result. The excess of sulphuric acid is then removed, and the sulphonic acids are heated with caustic potash to about 350° F. The mass gradually darkens till it becomes almost black, at which stage it dissolves in water with the formation of a rich purple solution, from which alizarin can be precipitated in abundance by the addition of sulphuric acid. A similar process was also devised by Perkin, in which the first step is the formation of dichloranthracene, $C_{14}H_8Cl_2$, by treating anthracene with chlorine. Subsequent treatment of this body with sulphuric acid gives anthraquinone disulphonic acid, $C_{14}H_6O_2(HSO_3)_2$. This is fused with potash, as described above, and the alizarin precipitated with sulphuric acid as before. Anthrapurpurin is formed, simultaneously with alizarin, in the processes given above. Its behavior as a dye is similar to that of alizarin, but it gives a brighter red. Pure alizarin, as obtained by sublimation, crystallizes in yellowish-red crystals, only slightly soluble in alcohol or water, but readily dissolving in alkalis. Chemically, alizarin is known as dioxyanthraquinone.

Alkahest, or **The House of Claës, The** (*'La Recherche de l'Absolu'*—The Search for the Absolute), is a striking novel by Honoré de Balzac. The central character, Balthazar Claës, is a wealthy chemist, the dream of whose life is to solve the mystery of matter. Gradually the quest becomes a fixed idea, for which money, family, health, sanity, are sacrificed, and Claës dies heart-broken and defeated. As foils to him stand his devoted wife and his eldest daughter Marguerite, noble women, the latter one of the finest creations of Balzac's genius. They sympathize sorrowfully yet tenderly with his ideal, and bear with true heroism the misery to which his mad course subjects them. The story belongs to that series of the Human Comedy known as « Philosophical Studies,» and appeared in 1834.

Al'kali (from the Arabic, *al*, «the,» and *qaliy*, «ashes»), a term originally used for the soluble part of «pot-ashes,» but since extended to include the hydrate or oxid of any of the metals lithium, sodium, potassium, cæsium and rubidium, or of the radical ammonium. The alkalis possess strongly basic properties, and (with the exception of ammonia) rapidly absorb carbon dioxid from the air, when moist, passing into the form of carbonates. They are all soluble in water, and nearly all of their compounds are also soluble. The real nature of the alkalis was first conclusively proved by Sir Humphry Davy when in 1807 he decomposed potash and soda by means of the electric current. Alkalis in concentrated solution exert a powerfully corrosive action on the skin, and even in very dilute solution they alter the color of certain vegetable infusions very markedly. This property is utilized for detecting free alkalis in solutions under examination, strips of bibulous paper impregnated with red infusion of litmus being moistened with the fluid to be tested. An exceedingly small amount of free alkali will transform the red color to a blue. The alkali metals are all monovalent.

The early chemist distinguished another class of substances, somewhat resembling the alkalis, as the «alkaline earths.» These include the oxids of calcium, strontium, and barium. The alkaline earths are basic in nature, and differ from the alkalis chiefly in being less soluble. Magnesium is sometimes included among the alkaline earths, but it falls more naturally into the zinc group. See ANTACID; SOILS.

Alkalim'etry, that branch of chemistry which treats of the quantitative estimation of alkalis present in a given solution. See ANALYSIS, CHEMICAL.

Alkaloids, organic bases, forming definite salts with acids and resembling in some respects the metals of the alkalis, hence the name. A number of basic nitrogenous compounds of marked physiological action and somewhat analogous in their chemical composition. It has been proposed to limit the word alkaloid to the group of basic nitrogenous principles found in plants, the somewhat similar bodies found in animals being termed ptomains (q.v.) and leucomains (q.v.). (See ANIMAL ALKALOIDS.) Some even class as alkaloids a series of feebly basic compounds prepared synthetically from the anilines, antipyrine, etc. Alkaloids are here considered in their strict sense as basic nitrogenous principles, products of the metabolism of plants.

Distribution.—Alkaloids are widely distributed throughout the plant kingdom; many plants contain them, and some plants contain a large number; opium, *Papaver somniferum*, for instance, contains a dozen or more alkaloids. The *Cinchona* family also contains many. In such cases, however, the alkaloids are, as a rule, very closely related in their chemical structure. Certain plant families contain many, others a few or none. Most of the alkaloids are found in the Dicotyledons, a few only are found in the Monocotyledons, Colchicum, and perhaps some of the *Liliaceæ*. The cryptogams do not seem to contain alkaloids in the true sense of the word, although ergot was supposed to contain some principles closely resembling alkaloids. The

Papaveraceæ, Solanaceæ, and *Ranunculaceæ* are particularly rich in alkaloids. The *Leguminoseæ, Rubiaceæ,* and *Umbelliferæ* contain many, while the large families of the *Compositæ* and *Labiateæ* contain very few. For the most part similar alkaloids are found in related plants, yet a few widely separated plants contain similar alkaloids, berberin being an example. As to their location in the plants themselves, alkaloids are found mostly in the fruit and seeds; many are found in the barks, and some in the roots. They are formed for the most part in the actively growing portions of the plant and are probably katabolic products of the plant metabolism. They are usually found in solutions combined with some plant acid in the cell sap, sometimes dissolved in oils or mucilage, and in many instances are stored up in secretory passages in the plant. As to the role that the alkaloids play in the plant economy it is difficult to state positively: they do not seem to be utilized by the plant as a source of energy and in some instances are even poisonous to the plant itself. One of the services they perform for the plant is to aid it in the struggle for existence by being poisonous to animals. The large quantities found in seeds is evidence for the support of this view.

For the most part alkaloids are solid, non-volatile, crystalline bodies, a few being liquid and volatile, that is, arecolin, nicotin, coniin, spartein. The former contain carbon, hydrogen, nitrogen, and oxygen. The three latter liquid alkaloids contain no oxygen and have a marked odor; the solid alkaloids possess no odor. With few exceptions the alkaloids are insoluble (or soluble with great difficulty) in water.

Chemically the alkaloids are divisible into five provisional groups, although it was at one time held that only those bodies belonging to the Pyridin group should be considered as alkaloids. These groups as classed by Brühl are (1) the Pyrrolidin group — containing an alkaloid from the coca leaf, hygrin; (2) the Pyridin group, which contains a large number, pilocarpin, pilocarpidin, arecolin, arecain, coniin, conydrin, piperin, nicotin, atropin, hyoscamin, cocain, pelleterein, spartein, cystisin, and others; (3) Chinolin group — containing cinchonin, quinin, cinchonidin, strychnin, brucin, curarin, and others; (4) Isochinolin group — containing the opium alkaloids, morphin, papaverin, narcotin, codein, thebain, hydrocotarnin, hydrastin, cannabin, berberin, corydalin; (5) alkaloids of undetermined relationship, a few only being of other than chemical interest, ergotinin, colchicin, veratrin, cevadin, jervin, rubijervin, aspidospermin, yohimbin, anhalonin, lupinin, gelsemin, aconitin, pseudoaconitin, japaconitin, delphinin, emetin, etc.

The internal chemical construction of all the alkaloids is extremely complex; for many it is unknown. Most are tertiary bases: a few are similar to the secondary amines in structure. Ammonia bases are also present in many. Many alkaloids acted on by strong alkalies are broken up into two components, a basic body and a nitrogen free, mostly aromatic acid. Most of the alkaloids react similarly to oxidizing agents; nitric acid, chromic acid, potassium ferrocyanide, and potassium permanganate are the most active. The last makes an efficient chemical antidote for many of them. A few alkaloids have been made synthetically. In the making, however, a related base has been necessary.

Physiologically the alkaloids are for the most part very active. Some have very little action, berberin, for example, while aconitin is one of the most toxic of substances. Nearly all of them have a marked affinity for nerve structures, on which a few have markedly poisonous action: some of them attacking the sensory nervous elements more particularly (aconitin, cocain); others exerting their greatest activity on the motor nervous structures, sometimes in the muscle plates (coniin, curarin) causing paralysis; others in the motor cells in the anterior horn cells of the spinal cord (strychnin). Still others exert their influence on the nerve cells of the brain (morphin, hyoscyamin).

History.—The history of the discovery of the alkaloids is about one hundred years old. Derosne of Paris first isolated from opium in 1803 a salt "of opium," as he termed it. This was a mixture of morphin and narcotin, and in 1806 Sertürner, a pharmacist of Hanover, first definitely discovered morphin. It was not until 1817, however, that the discovery was noticed. Following this in rapid succession different alkaloids were isolated,— narcotin and emetin in 1817, veratrin and strychnin in 1818, brucin and piperin in 1819, caffein, cinchonin, and quinin in 1820, and by 1835 at least 30 alkaloids were known. At the present time there are more than 200 known, and new ones are being discovered rapidly; detailed study of more important alkaloids will be found under their respective heads. See ANIMAL ALKALOIDS; PLANTS; POISONS.

Bibliography.—'Introduzione allo Studio degli Alcaloidi,' Icilio Guareschi; translated into German as 'Die Alkaloide,' by Kuntz Krause, is one of the most important of modern works. Also see 'La Constitution Chimique des Alcaloides Végétaux,' by Amé Pictet (2d ed. 1897); 'Die Pflanzen-Alkaloide,' by J. W. Brühl (1900). For studies of location in plants, see Rusby & Jelliffe, 'Morphology and Histology of Plants' (1899, with bibliography).

Al-Khowarazmi, Arabian mathematician of the 9th century. He was the librarian of Al-Mamun at Bagdad, and also worked in the Bagdad Observatory, where he carried on his astronomical and mathematical researches. Among his writings is a geographical treatise, 'Rasm Al-Ard,' giving the latitude and longitude of all places mentioned. He also wrote several mathematical treatises, including one on Hindu arithmetic, and 'Al Jabr wa'l Muqabalah,' discussing the quadratic equation and other algebraic problems; both of these were later translated into Latin, the latter giving algebra its name. See ALGEBRA, HISTORY OF ELEMENTS OF, and ARITHMETIC, HISTORY OF.

Alkmaar, a town of the Netherlands, in the province of North Holland, on the North Holland canal, and 20 m. N.N.W. of Amsterdam. It is regularly built, and its appearance has been much improved by the conversion of its ramparts into public walks. Its finest public buildings are the 15th-century church of St. Lawrence and a richly decorated Gothic town-house. It has manufactures of salt, sail-cloth, etc., and an extensive trade in cattle, corn, butter, and cheese. Among interesting events in its history are its successful defense against the Duke of Alva in 1573, and the invention of dam-

ask-weaving by a citizen, Paschier Lammertyn, in 1595. To the west stood the castle of the counts of Egmont. Pop. (1900) 18,275.

Alkoran. See KORAN.

Al'kyl, the radicals of the alcohols (for example, methyl CH_3; ethyl, C_2H_5; and propyl, C_3H_7) are collectively called alkyls. (See ALCOHOL.) A compound of an alkyl with a halogen is called an alkylogen; and the metallic alcoholates are frequently called alkoxids, since they may be regarded as double oxids of a metal and an alcohol radical.

All Hallows College, Drumcondra, Dublin, Ireland. The foreign missionary college of All Hallows, as its name implies, was instituted for the exclusive object of educating priests for the foreign missions, for the purpose of supplying with missionary priests those parts of the world where the Gospel had never been preached. The missionaries, however, going forth from its halls, were to have as a primary claim on their attention, the spiritual needs, to speak in native parlance, of the "Irish of the dispersion," who, owing chiefly to the effects of bad laws, had begun at that period to emigrate in large numbers from Ireland. All Hallows was founded in the year 1842 by the Rev. John Hand, a native of the diocese of Meath, Ireland, then a young man, but a few years previously ordained at Maynooth. It was formally opened on All Saints' Day of that year with only one student, a very small beginning indeed, but it increased in numbers and resources till it is now probably one of the great foreign missionary colleges in the world. It is at present, and has been for some time past, in charge of the Vincentian Fathers, and was never in a more flourishing condition. It shelters within its walls some 300 students, all destined for the foreign missions. It is pleasantly situated at Drumcondra, one of the suburbs of the metropolis, on a demesne of rich land, obtained for it through the efforts of Daniel O'Connell, at that time Lord Mayor of Dublin. A large number of Catholic priests in the United States received their philosophical and theological training at All Hallows.

REV. JOHN REYNOLDS,
Brooklyn, N. Y.

Al'lactite, a mineral found in Sweden, and crystallizing in small monoclinic prisms or tablets having the composition $7MnO.As_2O_5.4H_2O$. Its hardness is 4.5 and its specific gravity about 3.84. It exhibits double refraction to a marked degree, and varies in color from red to green, according to the direction from which it is viewed. This property has given it its name, "allactite," being derived from a Greek word meaning "to change." The variability in color is due to the varying absorption of the ordinary and extraordinary rays of the incident light. See PHYSICAL CRYSTALLOGRAPHY.

Allah, in Arabic, the name of God, a word compounded of the article *al*, and the word *Elah*, which signifies "the Adored" and "the Adorable," and synonymous with the singular of the Hebrew word *Elohim*. *Allah akbar* (God is great) is a Mohammedan war-cry.

Allahabad, an ancient city of India, capital of a division and district of the same name, as well as of the whole of the northwest provinces, 72 m. W. of Benares. The native town consists largely of mud houses. Its English suburb of Canningtown has much more of a European aspect. Among the remarkable buildings of Allahabad are a large triangular fort, occupying a point of land formed by the junction of the Ganges and Jumna; the Jumna Musjid, or great mosque; the mausoleum of Khosru; All Saints' Church; the Roman Catholic cathedral; the Muir Central College founded in 1874, the chief educational establishment of the northwest provinces; the Mayo Memorial and town hall. Allahabad is one of the chief resorts of Hindu pilgrims, who come partly to visit a sacred cave under the Chali Satum temple (whence it is said there is a subterranean passage to Benares), but chiefly to have their sins washed away by bathing in the waters of the sacred rivers of Ganges and Jumna at their junction, where believers see a third river, the Saraswati (which is in reality lost in the sands at a distance of 400 miles from Allahabad), mingle its current with those of the other two. A great fair held on 14 December is much attended by pilgrims. There are few manufactures. Allahabad forms a junction in the railway system between Bengal and Central India, and its trade is rapidly increasing. In the mutiny of 1857 it was the scene of a serious outbreak and massacre. Pop. (1901) 175,750. The division of Allahabad contains the districts of Cawnpur, Futtehpur, Hamirpur, Banda, Jhansi, Jalaun, Lalitpur, and Allahabad. The agriculture of the division is greatly promoted by a canal 310 miles long, connecting the Ganges and the Jumna. About five sixths of the surface is under cultivation, the principal crops being rice, pulse, wheat, tobacco, etc. Pop. (1901) 1,548,737.

Allan, Sir Hugh, founder of the Allan line of steamships: b. Scotland, 29 Sept. 1810; d. Edinburgh, 8 Dec. 1882. A clerk with limited education, he emigrated to Canada in 1824, was clerk in Montreal stores, became captain in the rebellion of 1837, and in 1838 succeeded his late employer as a partner in the shipping and shipbuilding business. In 1853 his firm began building iron screw steamships, and their first vessel, the Canadian, made its first voyage in 1855, two more being used as transports in the Crimean war. The Allan Line, after many disasters, gained a permanent footing, and has been a large element in developing Canadian prosperity. Sir Hugh was one of the projectors of the Canadian Pacific Railway, and prominent in the political investigations to which it led. He was a director in banking, telegraph, gold mining, and other large business enterprises, and was knighted in 1871.

Allan, Sir William, a distinguished Scottish artist: b. 1782; d. 1850. He was a fellow student with Wilkie in Edinburgh, afterward a student of the Royal Academy, London; then went to Saint Petersburg and remained for 10 years in the Russian dominions. In 1814 he returned to Scotland and publicly exhibited his pictures, one of which ('Circassian Captives') made his reputation. He now turned his attention to historical painting and produced scenes from Scottish history and battle scenes; among them two pictures of the battle of Waterloo, one from the British, the other from the French position, and delineating the actual scene and the incidents therein taking place at the moment chosen for the representation. One of these Waterloo pictures was purchased by the Duke of Wellington. He traveled ex-

tensively, visiting Italy, Greece, Asia Minor, Spain, and Barbary. In 1835 he became R.A., in 1838 president of the Scottish Academy; in 1842 he was knighted.

Allan, William, American military writer: b. Virginia, 1837; d. 1880. He was a lieutenant-colonel in the Confederate army during the Civil War. His works are: 'Jackson's Valley Campaign' (1862); 'The Battle-Fields of Virginia' (1867); and 'The Army of Northern Virginia.'

Al'lanite, a mineral, isomorphous with epidote, and containing rare metals of the Cerium and Yttrium groups. It is variable in composition, but is essentially a silicate of these metals, combined with aluminum, iron, and calcium. It occurs in Norway and Finland, and in the United States in Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Virginia, and North Carolina; also in Canada. It was named for Thomas Allan, of Edinburgh, who described it in 1808. (Also called orthite.)

Allan'toin, a-lan'tō-in, a substance found in the allantoic fluid of the cow, in the urine of sucking calves, in the leaf buds of the maple, and in the bark of the horse-chestnut tree. It is readily soluble in alcohol and crystallizes in monoclinic prisms having the formula $C_4H_6N_4O_3$. It may be formed by treating uric acid with boiling water and PbO_2. Compounds of allantoin with several of the metals are known.

Allantois, a structure appearing during the early development of vertebrate animals — reptiles, birds, and mammalia. It is largely made up of blood-vessels, and, especially in birds, attains a large size. It forms the inner lining to the shell, and may thus be viewed as the surface by means of which the respiration of the embryo is carried on. In mammalia the allantois is not so largely developed as in birds, and it enters largely into the formation of the placenta.

Al'legan, Mich., town and county-seat of Allegan County, 33 m. S. of Grand Rapids. It is situated on the Kalamazoo River and on the Cincinnati N., Lake Shore & M. S., and the Pére M. R.R.'s. It is in the midst of a fertile region, and a large dam on the river a few miles above the village affords valuable water power. Among its industries are mills of various kinds, carriage works, furniture factories, etc. It contains a public library, two banks, court house, city hall, and public schools. First settled in 1834. Pop. (1905) 3,941.

Allegation is the assertion, declaration, or statement by a party of what he can prove. Under the reformed method of procedure adopted in nearly if not all of the States of the Union, the general rule that the allegations in the pleadings and the proof must correspond has been greatly relaxed. Under our present system a failure to prove an immaterial averment cannot in general be a material variance at the trial, and will be disregarded. If the substance of the issue be proved it is sufficient. If a contract, for instance, agree in substance and legal effect with that stated in the complaint, the variance will be disregarded.

Alleghanies, a name sometimes used to designate the entire Appalachian mountain system, but more properly applied to the western range of this system in Pennsylvania, Maryland, Virginia, and West Virginia. They begin near the New York and Pennsylvania border — the Catskills forming a northern outline — and extend in a southwesterly direction into West Virginia, where the line of elevations is continued by other ranges across Tennessee. In the northern part the mountains have an elevation of about 2,000 feet (over 4,000 feet in the Catskills), but they gradually increase in altitude southward until in Virginia they rise to 4,500 feet above the sea. Throughout their extent they present a remarkably even crest-line with few gaps and isolated peaks. On the eastern side the slope is abrupt to the bottom of the longitudinal valley from 50 to 100 miles wide, which is limited on the east by the parallel range of the Blue Ridge; on the west the elevations fall off more gradually. The range forms the water-parting between the streams draining into the Atlantic Ocean and the Gulf of Mexico. The former receives the drainage from the eastern slope principally through the Delaware, Potomac, and James Rivers, while the Ohio River collects most of the waters on the western side. The range has been formed by uplift and folding of sedimentary strata, the abrupt edges of which are turned toward the east. Limestone, sandstones, and conglomerates are the predominant formations and range from the Cambrian to the Carboniferous systems. Immense coal-seams occur in the higher part of the series, forming the basis of a great mining industry. See APPALACHIANS.

Allegheny, Pa., a large manufacturing and residential city opposite Pittsburg on the right or north bank of the Allegheny river and stretching down along the Ohio river, here formed by the confluence of the Allegheny river with the Monongahela; connected with Pittsburg by three wooden and five modern steel bridges crossed by numerous electric railways. Is the home city for a large proportion of the business men of Pittsburg. Although having separate municipal governments Pittsburg and Allegheny form practically one great city of over half a million people; their business interests being based upon the same natural advantages and the same railroad and river transportation facilities being common to both.

Interior.— Allegheny has a river frontage of six and one-half miles and an area of over 5,000 acres. Originally laid out upon a small plateau slightly elevated above the river, it has gradually spread out over the surrounding hills which rise seven hundred feet above the river or thirteen hundred feet above sea level. The hill districts now made accessible by electric railways form a desirable home section. The city owns its own electric lighting plant and pumps its water from the Allegheny river at Montrose nine miles above the city. Has 180 miles of streets, over 100 miles paved, over 80 miles of sewers and 140 miles of water mains. There are two public parks, Allegheny Park, of 100 acres, in the centre of the city, and Riverview Park in the northern district.

The most noteworthy monuments are the Anderson monument at the corner of Federal and Ohio streets, the two most important thoroughfares, the Humboldt, Armstrong, Wash-

ington and Hampton battery in the Allegheny parks and the Soldier's on a height to the west.

Education.—An efficient public school system is maintained at a cost of about $400,000 a year. There are 27 public school buildings valued at over $2,000,000 and attended by 30,000 pupils.

Is the seat of the Western (Presbyterian), United Presbyterian, and the Reformed Presbyterian Theological Seminaries, and the Western University. The latter was founded in 1819 and is now attended by over 700 students. Under its control is the famous Allegheny Observatory located on a height in Riverview Park. In connection with the public schools a public library of some 20,000 volumes is maintained, located in the High School Building. The Carnegie Free Library of nearly 60,000 volumes, the first of the large number of libraries founded by the munificence of Andrew Carnegie, is located on one of the corners of the public square and is the most conspicuous building in the city.

Religion.— There are 111 churches, the most prominent edifices being St. Peter's (R. C.), Trinity (Ev. Luth.), North Avenue (M. E.), Emanuel (Prot. Epis.), and Sandusky Street (Baptist).

Benevolent Institutions.—Three modern well-equipped hospitals are maintained, viz., Allegheny General, Presbyterian, and Saint John's (Lutheran). Of orphan asylums and other benevolent institutions the most important are The Home of the Friendless, The Orphan Home for Colored Children, The Orphans' Home on Ridge Avenue, and the Saint Joseph's (R. C.) Orphan Asylum. Also the seat of the Western Penitentiary.

Trade and Manufacturing.— The system of slack water navigation now under construction by the United States government on both the Allegheny and Ohio rivers make this an important shipping centre especially for coal and other bulky products. The heaviest manufactures are those developed by Pennsylvania's coal and iron, foundries and blast furnaces, rolling mills, locomotive and car works, machinery, stoves and furnaces, plumbers' goods; other products are glass, white lead, and colors. There are also large flour mills and four large pickling and preserving establishments. At one time the city was the centre of the tanning industry of the United States and still has many large tanneries in operation. In 1900 there were reported 893 manufacturing establishments, with 20,804 employes and an output valued at $54,136,967, paying $10,352,502 for wages and using $50,122,503 capital.

Finances.— The assessed valuation in 1905 was over $95,000,000. The city's expenditures are over $2,500,000 a year, of which $400,000 goes for schools and $150,000 each for the police and fire departments. There are ten banks with an aggregate capital and surplus of $7,000,000.

Government.— The executive power is vested in a mayor elected for a three year term. The mayor appoints all the minor city officials and employes. The legislative power is vested in the city council of two chambers.

History and Population.— The settlement was laid out in 1788 and incorporated as a borough in 1828. The first settlers consisted largely of Scotch-Irish, later reinforced by a large influx of German immigrants. In 1840 it had a population of 10,089 and was granted a city charter. Its population according to the census of 1900 was 129,896 and its estimated population now (1906) is 145,000. Its greatest disasters were in 1874: a fire on July 4th wholly or partially destroyed 199 buildings, and three weeks later a heavy local flood swept away much property and cost 124 lives. EDWARD E. EGGERS,

Librarian Carnegie Free Library, Allegheny.

Allegheny College, a co-educational (Methodist Episcopal) institution in Meadville, Pa.; organized in 1815 reported at the end of 1905: Professors, 16; students, 290; volumes in the library, 20,000; grounds and buildings valued at $200,000; productive funds, $450,000; income, $42,500; graduates, 1,386.

Allegheny River, a river of Pennsylvania and New York; a headstream of the Ohio. It rises in Potter County, Pa., and joins the Monongahela at Pittsburg. Among its tributaries are French Creek and Clarion and Conemaugh rivers. Its length is about 400 miles, and it is navigable for about 150 miles above Pittsburg.

Allegiance is the obligation of fidelity and obedience which an individual owes to the government under which he lives, or to his sovereign in return for the protection he receives. It may be an absolute and permanent obligation, or it may be qualified and temporary one. The citizen or subject owes an absolute and permanent allegiance to his government or sovereign, or at least until, by some open and distinct act, he renounces it and becomes a citizen or subject of another government or another sovereign. While domiciled in this country the alien owes a temporary and local allegiance which continues during the period of his residence.

Publicists and statesmen everywhere recognize this obligation of temporary allegiance by an alien resident in a friendly country. In the case of Thrasher, a citizen of the United States resident in Cuba, who complained of injuries suffered from the government of that island, Mr. Webster, then secretary of state, made in 1851 a report to the President in answer to a resolution of the House of Representatives, in which he said: "Every foreigner born, residing in a country, owes to that country allegiance and obedience to its laws so long as he remains in it, as a duty upon him by the mere fact of his residence and that temporary protection which he enjoys, and is as much bound to obey its laws as native subjects or citizens. This is the universal understanding in all civilized states, and nowhere a more established doctrine than in this country."

Acquired allegiance is that kind of allegiance which binds a citizen who was born an alien, but has been naturalized.

Local allegiance is that which is due from an alien while resident in a country, in return for the protection afforded by the government.

Natural allegiance is that which results from the birth of a person within the territory and under the obedience of the government. It was at one time a fundamental principle of the common law of England that natural allegiance was perpetual and could not be renounced without consent of the sovereign. The same doctrine was maintained in the United States for some years. This principle has, however, been re-

pudiated by statute in both countries. The act of Congress enacted 27 July 1868 declared that «the right of expatriation is a natural and inherent right of all people, indispensable to the enjoyment of the right of life, liberty, and the pursuit of happiness. The British Naturalization Act of 1870 has practically the same provisions. The fourteenth amendment to the Constitution of the United States provides that «all persons born or naturalized in the United States and subject to the jurisdiction thereof are citizens of the United States and of the State wherein they reside.» The consequence of this amendment is that the individual owes allegiance to the State in which he resides, and to the Federal government, his duty to the latter being paramount.

Allegory (from Greek *allo*, something else, and *agoreuein*, to speak), a figurative representation, in which the signs (words or forms) signify something besides their literal or direct meaning, each meaning being complete in itself. In rhetoric, allegory is often but a continued simile. Parables and fables are a species of allegory; for example, the beautiful parable in one of the tales in the 'Arabian Nights,' in which the three religions, the Mohammedan, Jewish, and Christian, are compared to three similar rings, bequeathed to three brothers by their father. Sometimes whole works are allegorical, as 'Reynard the Fox,' Spenser's 'Faerie Queene,' and Bunyan's 'Pilgrim's Progress.' When an allegory is thus continued through long works it is indispensable to its success that not only the allegorical meaning should be appropriate, but that the story should have an interest of its own in the direct meaning apart from the allegorical signification. There was a time when every poem was taken as an allegory; even such works as those of Ariosto and Tasso were tortured from their true meaning and made to pass for allegorical pictures. No poet has made use of allegory in a more powerful and truly poetical manner than the great Dante. Allegory is often made use of in painting and sculpture as well as in literature.

Allegri, Gregorio, an Italian composer and a singer in the papal chapel, considered one of the most excellent composers of his time: b. Rome about 1580 (according to others 1590); d. there 1652. His «Miserere» has particularly distinguished him. It is even now regularly sung during Passion Week in the Sistine Chapel at Rome. Its subject is the fifty-seventh psalm (which in the Latin version begins with the word *Miserere*), and is composed for two choruses in five- and in four-part harmony. This composition was once esteemed so holy that whoever ventured to transcribe it was liable to excommunication. In 1770 Mozart, then only 14 years of age, disregarded this prohibition, and after two hearings made a correct copy of the original.

Allegro, an Italian word signifying gay, and used in music to express a more or less quick rate of movement. The degrees of quickness are indicated by additional qualifying words or by derivatives of the word *allegro*. Thus *allegretto* or *poco allegro* means rather lively; *allegro moderato, commodo, giusto*, moderately quick; *allegro maestoso,* quick but with dignity; *allegro assai* and *allegro molto*, very quick; *allegro con brio* or *con fuoco*, with fire and energy; *allegrissimo*, with the utmost rapidity. *Piu allegro* is a direction to play or sing a little quicker. *Presto* indicates a still quicker rate than *allegro*, but there is usually also this difference between the *presto* and *allegro* movements, that the former demands nothing more than rapid execution, while the latter requires to be performed with expression as well as quickness. The first movement of a symphony and other similar compositions is called the *allegro*. See MUSIC.

Alleine, Joseph, English nonconformist clergyman: b. Devizes, 1634; d. Taunton, 17 Nov. 1668. Educated at Oxford, he became assistant at St. Mary Magdalene's Church, Taunton, in 1655, but was ejected for nonconformity in 1662. He was the author of 'An Alarm to the Unconverted.'

Allemontite, a tin-white, metallic mineral, regarded as a native alloy of arsenic and antimony, $SbAs_3$. It usually occurs in fine-granular or mammillary forms. Its hardness is 3.5 and specific gravity about 6.20. It is found at Allemont in France, also in Bohemia and Germany.

Allen, Alexander Viets Griswold, Protestant theologian: b. Otis, Mass., 4 May 1841. Graduated Kenyon College, O., 1862, Andover Theological Seminary, 1865; rector St. John's Episcopal Church, Lawrence, Mass., 1865–7; professor of church history, Episcopal Theological School, Cambridge, since 1867. A prominent leader in modern religious thought; he has written 'Continuity of Christian Thought' (1884); 'Life of Jonathan Edwards' (1889); 'Religious Progress' (1893); 'Christian Institutions' (1897); 'Life and Letters of Phillips Brooks' (1900).

Allen, Alfred, author and playwright: b. Alfred, N. Y., 8 April 1866. He graduated at Alfred University, studied at the Johns Hopkins and Columbia universities and the American Academy of Dramatic Arts in which last he is now a professor. His plays are 'Jack the Giant Killer'; 'A Burglar Honeymoon'; 'Playmates'; and 'Head of the House'; all have been produced on the stage. Novels: 'The Heart of Don Vega'; 'Judge Lynch'; 'The Cup of Victory' (with Richard Hovey).

Allen, Charles Grant Blairfindie. See ALLEN, GRANT.

Allen, Charles Herbert, American diplomatist: b. Lowell, Mass., 15 April 1848. He graduated at Amherst 1869; associated with his father in the lumber business in Lowell; served in both branches of the State legislature, and in Congress in 1885–9; was defeated as Republican candidate for governor of Massachusetts, 1891; and succeeded Theodore Roosevelt as assistant secretary of the navy in May 1898. On the passage by Congress of the Porto Rico tariff and civil government bill, in April 1900, the President appointed him the first civil governor of Porto Rico; he resigned July 1901.

Allen, David Oliver, missionary: b. Barre, Mass., 1800; d. Lowell, Mass., 17 July 1863. He was graduated at Amherst College in 1823;

and became a missionary in western India 1827–53. He established schools in the province of Bombay, wrote tracts in Mahratta, and edited a new translation of the Bible in that language. He also wrote a 'History of India, Ancient and Modern' (1856).

Allen, Ebenezer, American soldier: b. Northampton, Mass., 17 Oct. 1743; d. 26 March 1806. He emigrated to Vermont in 1771, and was made a lieutenant in Col. Seth Warner's regiment of «Green Mountain Boys.» In 1776 he was a delegate to the conventions in the New Hampshire grants, and in 1777 to those which declared the State independent and framed its Constitution. In July of that year he was made captain in Herrick's battalion of «Rangers,» and took an active part in the battle of Bennington; in September he captured Mount Defiance; and he took fifty prisoners among the troops retreating from Ticonderoga. He afterward became major and continued to win distinction during the war. He lived at Burlington in his later years.

Allen, Edward Patrick, an American Roman Catholic clergyman: b. Lowell, Mass., 17 March 1853. He worked in the Lowell mills as a boy, acquiring his early education at an evening school and from local priests; graduated at Mount St. Mary's College, Emmitsburg, Md., in 1878; took a course in theology; was ordained a priest in 1881; was president of Mount St. Mary's College in 1884–97; and on 16 May 1897 was consecrated fifth bishop of Mobile, Ala.

Allen, Elisha Hunt, American legislator and diplomat: b. New Salem, Mass., 28 Jan. 1804; d. 1 Jan. 1883. Graduating at Williams College, 1823, he became a lawyer at Brattleboro, Vt., but soon removed to Bangor, Me., and was a member of the Maine legislature 1834–41, and speaker in 1838. He was elected representative to Congress in 1841. Removing to Boston in 1847, he was elected to the Massachusetts legislature in 1849. Appointed consul at Honolulu in 1852, he held that post till 1856, and thence till 1876 was chancellor, minister of finance, and chief justice of the Hawaiian kingdom. Several times during that period and from 1876 onward he was its minister to the United States and died in Washington, dean of the diplomatic corps.

Allen, Elizabeth Akers (Chase), American poet: b. Strong, Me., 9 Oct. 1832. She was married in 1860 to Paul Akers, the sculptor, who died in 1861; and in 1865 to E. M. Allen of New York. Her first volume, 'Forest Buds,' appeared under the pen name of «Florence Percy» (1855). Other works: 'The Silver Bridge and Other Poems' (1866); a volume of 'Poems' (1866), which contains 'Rock Me to Sleep, Mother' (her authorship of this popular ballad, once disputed, is proved in the New York *Times*, 27 May 1867); 'The High Top Sweeting and other Poems' (1891), 'Sunset-Song' (1902).

Allen, Ethan, American soldier: b. Litchfield, Conn., 10 Jan. 1737; d. 13 Feb. 1789. About 1769 he removed to Bennington, Vt. The Vermont territory had been given by the Crown to both New Hampshire and New York under conflicting grants; and when the dispute was settled (1764) in favor of New York, Gov. Wentworth of New Hampshire had already granted 128 townships, and continued to grant others up to the Revolution. New York at once proceeded to re-grant the same territory, but the indignant settlers drove out the surveyors, applying the «beech seal» (fresh-cut rods) to enforce their withdrawal. The English government ordered the *status quo* to be respected by New York, and further disorders averted by granting only ungranted lands; the New York authorities continued to send surveyors, their grantees persisted in attempting to take possession of their lands, and the New Hampshire grantees continued to eject both deputy sheriffs and claimants by armed force and to chastise them besides. Allen at once took part in the dispute and soon became a leader: an athletic and adventurous giant, he was now in his element. In 1770 he was appointed agent for the settlers at Albany, where they were to plead their rights; the decision went against them, and a fresh attempt being made to enforce New York rights, the settlers raised a regiment for defense, called «Green Mountain Boys,» of which Allen was made colonel. Tryon of New York, historically more renowned for vanity and bad temper than ability or success, proclaimed him an outlaw and offered £150 for his capture; but under Allen, Seth Warner, and other able partisan chiefs the settlers held New York at bay. Allen in 1774 answered publications in defense of the New York claims by a tract defending the Vermonters, reprinted in 1779. When the Revolution broke out Congress ordered Arnold to raise troops and seize the British fortresses on the New York border; but the Vermonters forestalled them by collecting a force of «Green Mountain Boys» at Castleton, Vt., under Allen's command, which on 10 May 1775, captured Ticonderoga and its garrison without a combat, and shortly after Crown Point and Skenesborough (Whitehall), giving them a mass of stores and the command of Lake Champlain. This action moved Congress to grant them the same pay as Continental soldiers, and to recommend the New York Assembly to employ them in the army under their own officers. Allen and Warner journeyed thither and asked admittance to the session; and after some grumbling over receiving proclaimed felons a heavy majority voted to admit Allen, and later to raise a regiment of Green Mountain Boys. Allen wrote a letter of thanks, and proposed an invasion of Canada, which was rejected. He then joined Schuyler's army as a volunteer, was sent on secret missions to Canada, meeting on the last one Col. John Brown, who agreed to join him in an invasion of Canada. Fort Chambly was captured; but Brown left Allen in the lurch at the attack on Montreal, and Allen was taken prisoner 25 September and sent to England. He was chained and treated with great severity, but after some months was sent to Halifax, N. S., and exchanged 6 May 1778. On returning to Vermont he was appointed commander of the militia, and Congress made him lieutenant-colonel in the regular army. The old land-grant feud still raged, and in the attempted British intrigue (1780–3) to have Vermont annex itself to Canada as a protection against New York, Allen paralyzed British military action by professing to consider a bribe for favorable action; later he was charged with treason, but the charge was

not sustained. He settled in Bennington and finally in Burlington, where he died. He was a member of the legislature; and after the war was a delegate to Congress, where he worked for the admission of Vermont as a State, which it had been by self-proclamation since 1777. It was not till 1789, however, that New York waived its claims, and Allen did not live to see the result. He wrote the story of his captivity (1779); and 'Reason the Only Oracle of Man' (1784), being a deist of the Paine stripe. (See Sparks' 'Life,' and Henry Hall's 'Ethan Allen,' 1892.)

Allen, Frederick De Forest, classical scholar: b. Oberlin, Ohio, 1844; d. Cambridge, Mass., 4 Aug. 1897. He graduated at Oberlin College 1863, and studied at Leipsic. From 1866 to 1880 he held professorships in the universities of Tennessee, Cincinnati, and Yale. In 1880 he accepted the chair of classical philology at Harvard, holding it until his death. He published an edition of Euripides' 'Medea' (1876), 'Remnants of Early Latin' (1880), a revision of Hadley's 'Greek Grammar' (1884), and 'Greek Versification in Inscriptions' (1880); besides contributing many papers to classical journals and editing numerous classics.

Allen, Fred Hovey, author and Congregational clergyman: b. Lyme, N. H., 1 Oct. 1845. He graduated at Hartford Theological Seminary and studied abroad. Later he became pastor at Boston and Abingdon, Mass., and editor of the Suffolk County *Journal*, Boston, and a lecturer on art. He has published: 'Modern German Masters' (1885); 'Recent German Art' (1885); 'Great Cathedrals of the World' (1886); 'Popular History of the Reformation' (1887); and edited numerous art works.

Allen, George William, Canadian statesman: b. Toronto 1822. Called to the bar in 1846 he became senator in 1867. For many years he was chairman of the Committee on Banking and Commerce. In 1891 he became member of the Queen's privy council for Canada. He presented the city of Toronto with the ground on which is built the Canadian Institute. He was for a long time chancellor of the University of Toronto.

Allen, Grant (Charles Grant Blairfindie Allen), essayist, novelist, naturalist: b. Kingston, Canada, 24 Feb. 1848; d. London, 25 Oct. 1899. He graduated at Oxford in 1871, and for a time was professor of logic and philosophy in Jamaica, but spent the greater part of his life in England. Widely known as a scientist in several departments, he aimed to popularize science, and his brilliant style contributed greatly to his success in this respect. His score or so of novels and works of light fiction attained great popularity, but though entertaining have only an ephemeral value. His outspoken agnosticism is reflected in many of his writings. In science his chief titles are, 'Physiological Æsthetics' (1877); 'The Color Sense' (1879); 'Evolutionist at Large' (1881); 'Flowers and Their Pedigrees' (1883); 'Charles Darwin' (1885); 'Force and Energy' (1888); 'Story of the Plants' (1896); 'Evolution of the Idea of God' (1897). In fiction the following were most widely read, 'This Mortal Coil' (1888); 'The Great Taboo' (1890); 'The Duchess of Powysland' (1891); 'The Woman Who Did' (1895); 'The British Barbarians' (1895); 'Under Sealed Orders' (1896).

Allen, Harrison, anatomist: b. Philadelphia, 17 April 1844; d. there, 14 Nov. 1897. He graduated M.D. at the University of Pennsylvania 1861; was assistant surgeon in the United States army 1862–5; professor of comparative anatomy and medical zoology in the University of Pennsylvania 1865–78, and of physiology 1878–95. He was the author of numerous articles and books on the subjects connected with his professorship, and of 'Studies in the Facial Region' (1874); 'Analysis of the Life Form in Art' (1875); 'System of Human Anatomy' (1880).

Allen, Henry, religious enthusiast: b. Newport, R. I., 14 June 1748; d. Northampton, N. H., 2 Feb. 1784. He was founder of the sect known as «Allenites» and made numerous converts in Nova Scotia. He asserted that Adam and Eve before the fall had not corporeal bodies, that the Bible is to be interpreted wholly in a mystic or spiritual sense, and denied the doctrine of the resurrection of the body. He was an eloquent preacher and published some sermons and hymns.

Allen, Henry Watkins, American soldier and public officer: b. Prince Edward County, Va., 29 April 1820; d. 22 April 1866. He removed in early youth to Missouri, where he was sent to Marion College; he subsequently became a teacher in Grand Gulf, Miss., studied law and entered practice there. He raised a company for Houston's Texas war against Mexico; and after the war was over resumed practice, and was sent to the legislature in 1846. Settling in Baton Rouge, he was elected to the Louisiana legislature in 1853. In 1859 he went to Italy, to share her struggle for independence against Austria; but arriving after it was over, made a tour of Europe, which he described in 'Travels of a Sugar Planter.' He was elected to the legislature in his absence. He was one of the Southern Whigs who joined the Democrats after the party break-up caused by the Kansas-Nebraska bill. At the opening of the War he was commissioned by the Confederacy lieutenant-colonel; later colonel, and military governor at Jackson. He was wounded at Shiloh; constructed fortifications at Vicksburg; was disabled at Baton Rouge; made brigadier-general September 1864; and shortly after elected governor of Louisiana. He was a vigorous and efficient magistrate, with almost dictatorial powers. After the War he migrated to Mexico and started the (English) Mexico *Times* in the city of Mexico, where he died.

Allen, Horace N., American minister: b. Delaware, Ohio, 23 April 1858. He graduated at Ohio Wesleyan University, and after a medical course went to China as Presbyterian missionary. Going to Korea in 1884 he was in Seoul at the time of the *coup d'état* of that year and saved the life of a prince related to the queen; he was thereupon made court physician and allowed to establish a hospital under government orders. He came to Washington in 1887 with the first Korean legation, and returned in 1890 as United States secretary of legation: won great confidence for sagacity and acquaintance with Korea and in 1897 was made United States minister

there. He has written ‹ Korean Tales ›; a chronological index of Korea's foreign relations; and many papers for the ‹ Korean Repository › and the ‹ Transactions of the Foreign Society of Korea.›

Allen, Horatio, American engineer: b. Schenectady, N. Y., 1802: d. 1889. Graduating at Columbia University in 1823, in 1826 he was resident engineer on the summit level of the Delaware & Hudson Canal, and was sent to England in 1828 to buy locomotives for its proposed railway. In 1829 he made the first locomotive trip in America at Honesdale, Pa., with the ‹ Stourbridge Lion.› He was chief engineer, 1829–34, of the South Carolina Railway, then the longest line in the world; and in 1838–42 was chief assistant engineer of the Croton Aqueduct. He was chief engineer and afterward president of the Erie Railway, consulting engineer of the Panama Railway and the Brooklyn Bridge; president of the American Society of Civil Engineers 1872–3. He invented the swivel cartruck.

Allen, Ira, younger brother of Ethan (q.v.) and a « Green Mountain Boy »: b. Cornwall, Conn., 21 April 1751; d. 7 Jan. 1814. He went to Vermont in 1772 and was an active supporter of Ethan in the « beech seal » proceedings. He was a member of the Vermont legislature 1776–7, and of the Vermont Constitutional Convention 1778; was its first secretary of state, then its treasurer, and surveyor-general. He was in the battle of Bennington, 1777. In 1780–1 he was a Vermont commissioner to Congress to contest the New York land claim. In 1789 he aided in organizing the University of Vermont; and in 1792 was a delegate to the convention that ratified the United States Constitution after Vermont's admission as a State. In 1795, as senior major-general of militia, he went to France and bought arms to be sold to the State; but in returning was captured by an English cruiser, taken to England, and charged with supplying the Irish rebels with arms, and only won his suit after eight years. Imprisoned in France in 1798 he returned to the United States in 1801. He wrote ‹ The Natural and Political History of Vermont › (London 1798); ‹ Statements Appended to the Olive Branch › (1807).

Allen, James Lane, American novelist: b. near Lexington, Ky., 1849. He was educated at Transylvania University in his native State and was successively an instructor in Kentucky University and Bethany College, West Virginia. In 1886 he removed to New York city and has since devoted himself entirely to literary pursuits. In his short stories and novels he has usually employed a Kentucky background, and his finished literary style, though somewhat too highly elaborated for the taste of the average reader, has been much admired by the more critical. His prose is characterized by a markedly poetic cast, and his realism is of that profounder kind which concerns itself with essential truths rather than with photographic fidelity to local types. His published books comprise: ‹ Flute and Violin › (1891); ‹ The Blue Grass Region and Other Sketches › (1892); ‹ John Gray, a Novel › (1893); ‹ A Kentucky Cardinal › (1894); ‹ Aftermath › (1895); ‹ A Summer in Arcady › (1896); ‹ The Choir Invisible › an expanded version of ‹ John Gray › (1897); ‹ The Reign of Law › (1900).

Allen, Jerome, American educator: b. Westminster West, Vt., 1830; d. 1894. He graduated at Amherst 1851; was professor and principal of several Western institutions thence till 1885; professor of pedagogy at the University of New York 1887–93. He was the chief agency in founding the New York School of Pedagogy and became its dean in 1889. He wrote a ‹ Handbook of Experimental Chemistry ›; ‹ Methods for Teachers in Grammar ›; ‹ Mind Studies for Young Teachers ›; and ‹ Temperament in Education.›

Allen, Joel Asaph, naturalist: b. Springfield, Mass., 19 July 1838. He studied under Agassiz at Harvard; took part in scientific expeditions to Brazil, the Rocky Mountains, and Florida 1865–9; was chief of the scientific party accompanying the Northern Pacific railroad survey 1873; and curator of vertebrate zoology in the American Museum of Natural History, New York, since 1885. He is author of ‹ Monographs of North American Rodentia › (with E. Coues, 1877); ‹ History of North American Pinnipedes › (1880); editor of ‹ Bulletin of Nuttall Ornithological Club › (1876–83), and of its successor, ‹ The Auk › (1884–1901); and has written hundreds of minor articles on ornithology and mammalogy.

Allen, Sir John Campbell, Canadian jurist: b. Kingslear, N. B., October 1817; d. Fredericton, N. B., 27 Sept. 1898. He was member of the New Brunswick House of Assembly 1856–65; solicitor-general 1856–7; speaker 1863–5; attorney-general 1865. He opposed the confederation of the Maritime Provinces and Canada. He was chief justice of the supreme court 1875–96, and was knighted by the queen 1889. His ‹ Law Reports › (6 vols.) and rules of the supreme court and acts of assembly relating to the practice of the courts are ranked highly.

Allen, John Romilly, English civil engineer and archæologist: b. London, 9 June 1847. Educated at Rugby and King's College, London, he became resident engineer on Baron de Reuter's Persian railways, and on the construction of the docks at Leith and at Boston, Lincolnshire. Has lectured on archæology at Edinburgh University College, London. His published books are: ‹ Design and Construction of Dock Walls › (1876); ‹ Christian Symbolism in Great Britain › (1887); ‹ Monumental History of the Early British Church › (1889); ‹ Early Christian Monuments of Scotland › (1903).

Allen, Joseph Henry, Unitarian clergyman and author: b. Northborough, Mass., 21 Aug. 1821; d. Cambridge, Mass., 20 March 1898. He graduated at Harvard 1840, and at its divinity school 1843, and filled pastorates at Northborough, Roxbury, Mass., Washington, D. C., Bangor, Me., and other places till 1878. For twelve years he was editor of the ‹ Christian Examiner.› He was also lecturer on ecclesiastical history at Harvard 1878–82, editor of the ‹ Unitarian Review › 1887–98, and a prolific writer on religious and philosophical subjects. His chief works are: ‹ Ten Discourses on Orthodoxy › (1849); ‹ Hebrew Men and Times › (1861); ‹ Christian History in its Three Great Periods › (3 vols. 1880–2); ‹ Positive Religion › (1892); ‹ Unitarianism Since the Reformation › (1894); translations of Renan's ‹ Anti-

Christ,' 'Origins of Christianity,' and 'History of the People of Israel.' A Latin grammar and other schoolbooks, prepared in collaboration with Prof. J. B. Greenough, are extensively used.

Allen, Karl Ferdinand, Danish historian: b. Copenhagen, 23 April 1811; d. there, 27 Dec. 1871. He became professor of history and northern archæology at the University of Copenhagen in 1862. His principal works are: 'Handbook of the History of the Fatherland' (1840), very democratic in tone, and 'History of the Three Northern Kingdoms' (1864-72).

Allen, Richard, preacher: b. 1760; d. Philadelphia, 26 March 1831. He organized the first church for colored people in the United States and was elected first bishop of the African Methodist Episcopal Church, 1816.

Allen, Robert, American soldier: b. Ohio about 1815; d. Geneva, Switzerland, 1886. Graduating at West Point in 1836, he was second lieutenant in the Seminole war, assistant quartermaster in the Mexican war, brevetted major for conduct at Cerro Gordo, and was in the battles that led to the capture of the City of Mexico. Appointed chief quartermaster of the Pacific division, he was transferred to Missouri at the outbreak of the Civil War, with headquarters in St. Louis, in charge of supplies and transportation for armies in the Mississippi Valley. He was made colonel in 1862, brigadier-general of volunteers 1863, brevet brigadier-general in the regular army 1864, brevet major-general 1865. From November 1863 to 1866 he was chief quartermaster of the Mississippi Valley with headquarters at Louisville, outfitted Sherman's march across country to Chattanooga, and the Kentucky, Virginia, and North Carolina expeditions. After serving a second time as chief quartermaster of the Pacific division he was retired in 1878.

Allen, Thomas, landscape and animal painter: b. St. Louis, 19 Oct. 1849. He studied at Washington University, graduated at Royal Academy of Düsseldorf, and studied in France three years. Has frequently exhibited at the Paris salons and was a judge of awards at the World's Fair, Chicago, 1893. His studio is in Boston, Mass.

Allen, Viola, American actress: b. 1867; made her début at the age of 15 at Madison Square Theatre, N. Y., in 'Esmeralda.' She has played leading classical, Shakespearean, and comedy roles with Lawrence Barrett, Salvini, Joseph Jefferson, and W. J. Florence. Between 1893–1900 created and played parts in 'Sowing the Wind,' 'The Masqueraders,' 'Under the Red Robe,' and starred in Hall Caine's 'Christian' and F. M. Crawford's 'In the Palace of the King.'

Allen, Walter, American author and journalist: b. Boston, Mass., 21 March 1840. He graduated at Yale in 1863; served in the paymaster's department of the navy, 1864–5; has been connected with leading newspapers in Portland, Me., Cincinnati, Boston, and New York, and contributed to the periodicals: and was appointed by President Hayes to investigate the condition of the Ponca Indians. He was assistant editor of Webster's International Dictionary and author of 'Governor Chamberlain's Administration in South Carolina' and 'Life of Gen. U. S. Grant.'

Allen, William, Cardinal, English ecclesiastic: b. 1532 in Lancashire, studied at Oxford and was Fellow of Oriel College. Owing to the persecution of Catholics under Queen Elizabeth he left England, and in 1568 he, with the assistance of Dr. Vendeville, founded an English College at Douay, where aspirants to the priesthood might obtain the instruction denied to them at home. During the first five years of its existence, this college trained and sent back to England over 100 priests. Another of his claims to the gratitude of English-speaking Catholics is that while professor at Douay, in collaboration with Gregory Martins and Richard Bristow he translated the Bible from the Latin Vulgate into English. This translation is known as the Douay Bible (q. v.) and is the one generally used by Catholics in England and America.

Allen, William, American preacher and miscellaneous writer: b. Pittsfield, Mass., 2 Jan. 1784; d. Northampton, Mass., 16 July 1868. He became president of Dartmouth University in 1817, and was president of Bowdoin College 1820–39. Of numerous works, both in prose and verse, the best known is 'American Biographical and Historical Dictionary' (3d ed. 1857).

Allen, William, American public official: b. Edenton, N. C., 1806; d. 11 July 1879. He studied law at Chillicothe, Ohio, was admitted to the bar at 21, and in three years had become noted as a coming leader. In 1832 he was elected (Democratic) member of Congress by one vote, the youngest member of the Twenty-second Congress. He was a leading champion of his party; took an active part in the 1836 canvass for Van Buren, and was given the United States senatorship by the Democrats at the earliest age of any senator before or since. He was re-elected in 1843, and in 1848 was tendered the nomination for the Presidency by the supporters of both Cass and Van Buren, but refused from loyalty to Cass. After the expiration of his term Mr. Allen took no further part in public life for nearly a quarter of a century, till 1873, when he was elected governor of Ohio: again nominated in 1875 as a "rag-money" champion, he was defeated by Rutherford B. Hayes. His stentorian voice gave him the Congressional nickname of the "Ohio Gong"; and he is credited with the famous slogan of the campaign of 1844 on the question of the northwestern boundary, "Fifty-four forty or fight."

Allen, William Francis, historian and essayist: b. Northborough, Mass., 5 Sept. 1830; d. 9 Dec. 1889. He graduated Harvard in 1851; studied at Berlin, Göttingen, and Rome, 1854–6; was professor of Latin and history in the University of Wisconsin 1867–89 and is noted as a scholar of wide and varied attainments, equally strong in the linguistic, historical, and archæological sides of his subjects. A list of his writings covers thirty 12mo. pages. Three of especial interest may be found in the Transactions of the American Philological Association for the years given: 'The Battle of Mons Graupius' (1880); '*Lex Curiata de Imperio*' (1888); 'The Monetary Crisis in Rome, A.D. 33' (1887).

Allen, William Henry, American naval officer: b. Providence, R. I., 1784; d. 1813. He entered the navy in 1800 and served in some of the greatest naval battles in American history.

For bravery displayed on the Chesapeake and United States he was made commander of the brig Argus in June 1813. He did great damage to English commerce in the Irish Channel, capturing in a month 27 ships. In a few days the Argus was taken by the English brig Pelican. In the battle Allen was shot, died soon afterward, and was buried with military honors in Plymouth, England.

Allen, William Vincent, American politician: b. 1847; leader in the People's or Populist party; became senator from Nebraska in 1893. In the memorable special session of 1893 he took a prominent part in opposing the repeal of the silver purchase act. He was chairman of the Populist national convention of 1896, and instrumental in obtaining its indorsement of William Jennings Bryan for President.

Allen, Willis Boyd, American writer: b. Maine, 1855. Besides a collection of verse, entitled 'In the Morning,' he has written several books for young people, including 'The Red Mountain of Alaska,' 'Pine Cones,' (1885); 'Silver Rags' (1886), 'Kelp,' 'Navy Blue' (1888); 'The Mammoth-Hunters.'

Allen, Zachariah, American inventor: b. Providence, R. I., 15 Sept. 1795; d. 17 March 1882. He was graduated at Brown University in 1813, and was admitted to the bar in 1815, but soon turned his attention to manufacturing. He traveled in Europe 1825, to study manufacturing methods, and on his return published the 'Practical Tourist.' He invented in 1821 the first hot-air furnace for household use; in 1833 the automatic cut-off valve for steam engines; and later an improved fire engine, extension rollers, and a storage system for water-power. He first suggested the system of mutual mill insurance, and drafted laws to regulate the sale of explosive oils. He was the first to compute the motive power of Niagara. He was a member from 1822 and president from 1880 of the Rhode Island Historical Society. He published 'The Science of Mechanics' (1829); 'Philosophy of the Mechanics of Nature' (1851); 'Solar Light and Heat, the Source and Supply' (1879); etc.

Allen-a-Dale, the friend and confidant of Robin Hood in the Robin Hood ballads.

Allenites. See Allen, Henry.

Allentown, Pa., city and county-seat of Lehigh County on the Lehigh Valley, the Philadelphia & Reading, and the Central of New Jersey R.R.'s, six miles S.W. of Bethlehem, 18 miles S.W. of Easton, and 55 miles N.W. of Philadelphia. It was founded about 1752 by William Allen, Esq., Chief Justice of the Province of Pennsylvania, father-in-law of Governor John Penn, and a great friend of the Penn family, from whom he derived his grants of land, and named Allentown in honor of its founder. Here Colonel James Bird displayed much heroism in the wars against the Indians; here, during the Revolution, the bells now in Christ Church, Philadelphia, were concealed by the Americans; and here, in 1799, John Fries (q.v.), of "Fries Rebellion" notoriety, fomented the German opposition to the "window tax." Inhabited at first by a few wealthy and unenterprising Germans, and by the influence of the neighboring towns cut off for several years from the different post routes, it remained unprogressive until, in 1811, by the division of Northampton County, it became the seat of justice of Lehigh County, and by an act of the Legislature passed 18 Mar. 1811, was incorporated as Northampton Borough. With its advance to the rank of a county-seat, the town improved rapidly, and its accessibility to deposits of limestone, iron ore, zinc, cement, etc., added to its increasing importance in trade and wealth. An inadequate water supply, one of its chief drawbacks, was removed in 1828 by the organization of a water company, and the city now owns and operates its water-works. In 1838 the original name of the town was restored, and in 1867 it received a special charter. Allentown now ranks second only to Paterson in the United States for the manufacture of silks, and has considerable manufactures of iron and steel, furniture, cement, thread, and cigars. The large courthouse, fine hospital, spacious prison, and other public buildings are of hewn limestone. The numerous educational establishments include Muhlenberg College, a Lutheran institution founded in 1867; the Allentown College for Women; a theological seminary, and a military institute. The city is governed under a charter of 1889 by a council divided into an upper house of 11 members and a lower house of 22 members, presided over by a mayor, who is elected triennially. The city's annual income is about $450,000. The inhabitants are largely of German descent, and German is still commonly spoken. Pop. (1890) 25,228; (1900) 35,416.

Allerton, Isaac, one of the 'Pilgrim Fathers': b. England about 1583; d. New Haven, Conn., 1659. He was one of the most influential members of the Plymouth Colony, but on account of some disagreement with his associates he removed to New Amsterdam in 1631, and later to New Haven. Mary Allerton, his daughter, was the latest survivor of the original Mayflower company.

All Hallows. See All Saints' Day.

Alliaceous Plants. See Allium.

Alliance, O., city of Stark co., situated on the Mahoning River, at the junction of the Alliance & Mahoning, Lake Erie, Pittsburg, Fort Wayne & Chicago, and other R.R.'s, 56 miles S.S.E. of Cleveland. It is in a thriving agricultural region, and is a busy industrial centre with manufactures of agricultural implements, white lead, terra cotta ware, and extensive steel works, manufacturing heavy machinery, structural iron work, boilers, cranes, gun carriages, steam hammers, and drop forgings. The first settlement, made in 1838, was known at Freedom until 1850, when the name was altered to Alliance. Its principal educational establishment, Mount Union College, a Methodist Episcopal institution, was founded in 1846. Alliance, incorporated as a city under a charter of 1854, is governed by a mayor, elected every two years, and by a council of 12 members. Pop. (1890) 7,607; (1900) 8,974.

Alliance of the Reformed Churches Holding the Presbyterian System, a voluntary organization popularly styled the Presbyterian Alliance, formed in London in 1875. Its councils have much moral significance but possess no legislative authority. Rather more than 90 Presbyterian bodies are represented in the Alliance, with some 25,000,000 adherents in all parts of the world. The first General Council of the

Alliance met in Edinburgh in 1877; and the subsequent councils were held in Philadelphia, 1880; Belfast, 1884; London, 1888; Toronto, 1892; Glasgow, 1896; Washington, 1899.

Allibone, Samuel Austin, bibliographer and librarian: b. Philadelphia, 17 April 1816; d. Lucerne, Switzerland, 2 Sept. 1889. For a time he engaged in mercantile pursuits; was book-editor of the American Sunday-School Union, 1867–73; and in 1879 was appointed librarian of the Lenox Library, New York. He is best known by his 'Critical Dictionary of English Literature and British and American Authors' (3 vols. 1854–71), a monumental work that cost him 20 years of labor. It contains notices of 46,499 authors, with extracts from reviews of their works, and 40 classified indexes of subjects. It is an indispensable reference work for libraries and students. A supplement containing over 37,000 authors, by John Foster Kirk, appeared in two volumes, 1891. Others of Allibone's works are: 'Poetical Quotations from Chaucer to Tennyson' (1873); 'Prose Quotations from Socrates to Macaulay' (1876); 'Great Authors of all Ages: Selections' (1880).

Allice, or **Allis** (Fr. *alose,* from Lat. *alausa*), the larger European shad (*Alosa vulgaris*), about 20 inches long. There is but one other shad in Europe, the twaite. In the Rhine valley both are called *maifisch.* See SHAD; TWAITE.

Allier, äl-lē-ā, a central department of France, intersected by the river Allier and partly bounded by the Loire; surface diversified by offsets of the Cevennes and other ranges, rising in the south to over 4,000 feet, and in general richly wooded. It has extensive beds of coal as well as other minerals, which are actively worked, there being several flourishing centres of mining and manufacturing enterprise; mineral waters at Vichy, Bourbon, L'Archambault, etc. Large numbers of sheep and cattle are bred. Area, 2,822 miles. Capital, Moulins. Pop. 500,000.

Allier, a river of France, tributary of the Loire, rising in the department of Lozère and flowing northward about 200 miles through Lozère, Upper Loire, Puy de Dôme, and Allier.

Allies, Jabez, English antiquary, and one of the earliest writers on folklore: b. Sulsley, 22 Oct. 1787; d. 29 Jan. 1856. He devoted his life to the study of the antiquities in his native county, embodying the results in his monumental work, 'The Ancient British, Roman, and Saxon Antiquities and Folklore of Worcestershire' (1852).

Alligator, the name of a genus of crocodilian reptiles derived from a corruption of the Spanish *el lagarto,* "lizard," from the Latin *lacertus,* a lizard. Alligators differ from crocodiles mainly in having relatively short and broad snouts and by the circumstance that as a rule the first and fourth tooth on each side of the lower jaw enter into pits in the upper jaw, whereas those of crocodiles slide outside of the jaw and are visible. The caymans of South America may be included in the general term. These reptiles are confined mainly to the rivers of the New World, in which they typically represent the crocodiles of the eastern hemisphere, but there is one species in China (*Alligator sinensis*) first made known in 1879, and resembling the South American species. The best-known species are the alligator of the southern States (*Alligator mississippiensis*); the cayman of Surinam and Guiana (*A palpebrosus*), and the spectacled alligator (*A. sclerops*), found in Brazil. In the water a full-grown alligator is a formidable animal, on account of its great size and strength. These reptiles swim with wonderful celerity, impelled by their long, laterally-compressed, and powerful tails. On land their motions are proportionally slow and embarrassed, owing to their weight, the shortness of their legs, and generally unwieldy proportions. It grows to the length of 15 or possibly 20 feet, and is covered above by a dense armor of horny scales.

Under the throat of this animal are two openings or pores, the excretory ducts from glands which pour out a strong, musky fluid, giving the alligator a peculiarly unpleasant smell. In the spring of the year, when the males are under the excitement of the sexual propensity, they frequently utter a loud roar, which, from its harshness and reverberation, resembles distant thunder, especially where numbers are at the same time engaged. At this period frequent and terrible battles take place between the males, which terminate in the discomfiture and retreat of one of the parties. The females make their nests in a curious manner, on the banks of rivers or lagoons, generally in the marshes, along which, at a short distance from the water, the nests are arranged somewhat like an encampment. They are obtuse cones four feet high, and about four feet in diameter at the base, built of mud and grass. A floor of such mortar is first spread upon the ground, on which a layer of eggs, having hard shells and larger than those of a common hen, are deposited. Upon these another layer of mortar, seven or eight inches in thickness, is spread, and then another bed of eggs; and this is repeated nearly to the top. From 100 to 200 eggs may be found in one nest. It is not ascertained whether each female watches her own nest exclusively, or attends to more than her own brood. It is unquestionable, however, that the females keep near the nests and take the young under their vigilant care as soon as they are hatched, defending them with great perseverance and courage. The young may be seen following the mother through the water like a brood of chickens following a hen. When basking in the sun on shore, the young are heard whining and yelping about the mother, not unlike young puppies. In situations where alligators are not exposed to much disturbance the sites of the nests appear to be very much frequented, as the grass and reeds are beaten down for several acres around. The young, when first hatched, are very feeble and helpless, and are devoured by birds of prey, soft-shelled turtles, etc., as well as by the male alligators, until they grow old enough to defend themselves. As the eggs are also eagerly sought by vultures and other animals the race would speedily become extinct but for the great fecundity of the females.

The alligator is generally considered as disposed to retire from man, but this is only where they are frequently disturbed. In situations where they are seldom or never interrupted they have shown a ferocity and perseverance of the most alarming character in attacking individuals in boats, rearing their heads from the water

and snapping their jaws in a threatening manner. At present alligators, though still numerous in the remoter parts of Florida and Louisiana, are no longer regarded as very dangerous. Their numbers annually decrease, and at no distant period they must be nearly, if not quite, exterminated. In the winter the alligators spend a great part of their time in deep holes, which they make in the marshy banks of rivers, etc. They feed on fishes, reptiles, small quadrupeds (dogs if they can get them), or carrion, and though very voracious are capable of existing a long time without food. Compare CROCODILE; and see CAYMAN; JACARE.

Alligator-apple. See CUSTARD-APPLE.

Alligator-fish, one of the *Agonidæ,* a family of fish whose slender bodies are armored by large bony plates. One species 12 inches long (*Podothecus acipenserinus*) is found on the northern Pacific coast.

Alligator-gar, the immense greenish colored gar (*Litholepis tristæchus*) found in the southern States and southward through North America, and sometimes measuring 10 feet. See GAR.

Alligator-lizard, any member of the genus *Sceloporus,* which, although iguanid, has many small species without the typical iguanid characteristics. They abound in Mexico and the southwestern United States, and one species (*Sceloporus undulatus*) is the familiar "fence lizard" of the colder States. Though often inconspicuously colored on the back except for black crosslines, the throat and inferior surfaces are generally striking in color, and frequently there are light lines along the sides. They are often ignorantly called poisonous, but all are harmless.

Alligator-pear, or **Avocado-pear,** a tree, *Persea gratissima,* of the natural order *Lauraceæ,* indigenous to subtropical and tropical America and widely cultivated in warm countries for its more or less pear-shaped, purple- or green-skinned fruits, each of which contains a single seed embedded in a yellowish-green edible marrow-like pulp. Wherever it grows the alligator-pear is highly prized as a salad and is usually served with pepper, salt, and vinegar, or with wine and spice, but natives of temperate climates usually have to acquire a taste for it. It is rich in oil, which may be used in soap-making and in lighting. The seeds yield a black dye. Little beyond the selection of chance seedlings has been done to obtain improved varieties. Seedlings are easily raised and begin to bear in about five years if planted in good soil in warm places. Except in southern Florida and southern California the avocado-pear does not produce palatable fruit in the United States. The American market, therefore, which is limited to the larger cities, is mainly supplied from Hawaii, Mexico, and the West Indies. The fruit is sometimes called midshipman's butter and aguacate.

Alligator-terrapin, -tortoise, or **-turtle,** the snapping-turtle; more particularly, a very large species (*Macrochelys lacertina*) which is eaten and esteemed as a delicacy in the lower valley of the Mississippi. It sometimes weighs 50 pounds.

Allingham, Helen (PATERSON), English artist: b. 26 Sept. 1848. Received her art education in the Royal Academy Schools, and married the Irish poet, William Allingham (q.v.), in 1874. She has drawn much in black and white for the 'Graphic' and other periodicals, and her work as an illustrator has been much admired.

Allingham, William, Irish poet: b. Ballyshannon, Ireland, 19 March 1824; d. Hampstead, 18 Nov. 1889. From 1846 to his retirement in 1870 he held various posts in the Irish customs service. He was sub-editor of 'Fraser's Magazine,' 1870–4, when he succeeded James Anthony Froude as editor, and conducted it with ability until 1879. At its best Allingham's poetry is excellent, being simple, clear, and graceful, and whether pathetic, sportive, or descriptive is always characterized by delicate artistic expression. His best work is in the volume called 'Day and Night Songs' (1854). 'Laurence Bloomfield in Ireland' (1864), a long poem which has been called "the epic of Irish philanthropic landlordism," has a wealth of fine description, but was not a public success. Other volumes are, 'Poems' (1850), 'The Ballad Book' (1864), 'Songs, Ballads, and Stories' (1877). 'Collected Poetical Works' (6 vols. 1888–93).

Allison, William Boyd, American legislator: b. Perry, Ohio, 2 March 1829. A farmer's son, he received an excellent education, first at Allegheny College, Pa., then at Western Reserve College, Ohio. Studying law, he practised in his native State till 1857, when he removed to Dubuque, Iowa. An ardent Republican and a trusted local political leader, he was sent as a delegate to the Republican national convention in Chicago in 1860, which nominated Lincoln. In the early part of the Civil War he served on the governor's staff, and was actively engaged in raising troops for the Union army. In 1863 he was elected to Congress, and served by successive re-elections till 1869; on 4 March 1873 he was elected to the United States Senate, and has been four times re-elected, in 1878, 1884, 1890, and 1896, his nearly 30 years of service making him one of the oldest as he has always been among the most influential leaders. He has served on many important committees; and as chairman of the Finance Committee in 1878 was the chief author of the bill that committee reported for the purchase of silver bullion, usually known as the Bland-Allison Act, for the purchase of silver bullion (see BLAND SILVER BILL), a compromise from the free-coinage bill of Congressman Bland. He has repeatedly been a strong candidate in Republican national conventions for the presidency; and was offered the secretaryship of the treasury by both Garfield and Harrison. In 1892 he was a representative of the United States at the Brussels Monetary Conference.

All is True, a play attributed to Shakespeare. The burning of the Globe Theatre (29 March 1613) while the piece was being played destroyed the manuscript. Parts of the drama were incorporated into the play of 'Henry VIII.'

Alliteration, the succession or frequent occurrence of words beginning with the same consonant. In the older Scandinavian, German, and Anglo-Saxon poetry it served instead of rhyme. It is found in early English poetry with the same function. As thus used it had a certain regularity of accent and emphasis. In 'Piers Plow-

man' the line is constructed with two hemistichs, the former with two words beginning with the alliterative letter, and the latter with one, thus:

"Her *r*obe was full *r*ich with *r*ed scarlet engreyned."

The poetry of widely separated nations exhibits this device, it being found both in India and in Finland. It still remains in Icelandic poetry. Early in the 17th century English writers ran to great extravagance in the use of alliteration, both in prose and poetry. It is said that preachers from their pulpits addressed their hearers as « chickens of the church » and « sweet swallows of salvation.» No other device of composition so easily lends itself to fanciful conceits or ingenious trifling. The ease with which devices may be marshaled would hardly tend to make the ordinary reader appreciative of Churchill's description of himself as one

"Who often, but without success, had prayed
For apt alliteration's artful aid."

But the couplet itself is a striking proof of its own truth, for it shows that the poet did not know what alliteration is: it must be of consonants, not vowels, and even so his *a*'s are alike only to the eye, not the ear. All good poets have used it to lend musical beauty or emphasis to their verse, though it can be over-used or misused. Following are a few from the chief American poets:

"And the *s*park *s*truck out by that *s*teed in his *f*light
Kindled the land into *f*lame with its heat."
LONGFELLOW.

"It carves the *b*ow of *b*eauty there,
And the *r*ipples in *r*hymes the oar forsake."
EMERSON.

"Of *w*ailing *w*inds, and naked *w*oods." BRYANT.

"And *h*ark! *h*ow clear bold chanticleer,
*W*armed with the new *w*ine of the year."
LOWELL.

"*S*tole with *s*oft *s*teps the shining *s*tairway through."
HOLMES.

"What a *t*ale of *t*error now their *t*urbulency *t*ells!"
POE.

"Across the *m*ournful *m*arbles play." WHITTIER.

Allium, a genus of about 250 perennial, rarely biennial, bulbous herbs of the natural order *Liliaceæ,* mainly indigenous to the colder parts of the northern hemisphere. The leaves are generally long and narrow, often, however, cylindrical and hollow; the flowers in umbels, often with bulblets among them. Many of the species are economically important; for instance, *Allium cepa,* the onion; *Allium sativum,* garlic; *Allium porrum,* leek; *Allium ascalonicum,* shallot; *Allium schœnoprasum,* chive; *Allium scorodoprasum,* rocambole, each of which is treated separately under its common name. Several uncultivated members of the genus are also used as food in countries where they grow wild. *Allium vineale,* wild onion or wild garlic, a European species introduced into the United States, is a troublesome weed, especially in New England pastures, since it imparts a strong flavor of garlic to the milk of cows feeding upon it. (See GARLIC.) Many species are natives of the United States, but none of them have been cultivated for food; some, however, are planted for ornament. Perhaps the most common eastern species are *Allium cernuum, Allium canadense,* and *Allium tricoccum,* the last generally known as the wild leek, a broad-leaved species which grows in moist woods, from Maine to North Carolina and westward to Wisconsin. Some of the hardy species are grown for ornament in gardens; for example, *Allium moly* and *Allium roseum,* from Europe; *Allium victorialis,* from Siberia; *Allium acuminatum,* from the western States. Others, especially *Allium neapolitanum,* a tender European species, are often grown in greenhouses.

Allmers, Hermann Ludwig, äl-merss, hĕr'man lüt'vik, German poet and author: b. Rechtenfleth, 11 Feb. 1821. His 'Idle Days in Rome' (1869; 9th ed. 1896) was widely read. Others are: 'Captain Böse' (1882); 'Fromm und Frei' (1889), a volume of religious poems; 'From an Old and Young Past Time' (1895); 'Collected Works' (Oldenburg, 6 vols. 1891–5).

Allmouth, a fish. See GOOSEFISH.

Alloa, a river port of Scotland, pleasantly situated on the north side of the Forth, 5 m. from Stirling, and in the county of Clackmannan. It is irregularly built, but contains some good streets and buildings, including the parish church, the county court-house, the town-hall, and the public baths. It carries on several manufactures, chief of which are ale, whiskey, woolen yarn, and bottles. There are some large collieries in the neighborhood. Alloa has an excellent harbor, from which it exports coal, ale, and fire-brick, and imports timber, hemp, oak-bark, grain, etc. A new wet dock was opened in 1881. The river is here crossed by a viaduct of the North British Railway. There is an ancient tower in the vicinity, once the residence of the Erskine family. Pop. (1901) 11,417.

Allobroges, the name of a people who lived in ancient Gallia Narbonensis and occupied the country below the Lake of Geneva and the Rhone, now included in Savoy and the French province of Dauphiné. They long struggled for their independence against the Romans, but were finally subjugated by Fabius Maximus.

Allocution, an address, a term particularly applied to certain addresses made by the Pope to the cardinals.

Allodium («without vassalage»). Applied to lands, allodium, or allodial tenure, signifies an estate held by absolute ownership, without regarding any superior to whom any duty is due on account thereof. The title to land in the United States is essentially allodial, and every tenant in fee simple has an absolute and unqualified dominion over it; still, in technical language, his estate is said to be in fee, a term implying a feudal relation, although such a relation has ceased to exist in any form, while in many of the States of the Union the lands have been declared to be allodial.

Allopathy. See THERAPEUTICS.

Al'lophane, al'ō-fān; from the Greek *allos,* «other,» and *phanos,* «appearing,» in allusion to its change of appearance before the blowpipe, a native silicate of aluminum, having the formula $Al_2SiO_5 + 5H_2O$, and occurring in thin, amorphous, brittle incrustations, with a hardness of 3, and a specific gravity of about 1.87. It is found in a great variety of colors, due to the presence of other minerals. In the United States it occurs in Massachusetts, Connecticut, Pennsylvania, and Tennessee.

Allosaurus, an extinct carnivorous dinosaur of gigantic size, inhabiting North America during the Jurassic Period. It was one of the largest of flesh-eating animals, exceeding 30 feet in length, and comparable with an elephant in bulk. The animal was a biped with long hind legs, small fore legs not reaching the ground, and long massive tail. The jaws are three feet long, with pointed, sharp-edged teeth, and the toes armed with large sharp claws, those of the fore foot being especially powerful. The hind feet somewhat resemble those of birds. Fossil skeletons of herbivorous dinosaurs frequently show deep scratches and scorings on the softer edges of the bone, and broken-off teeth of Allosaurus are very often found associated with them, showing that this animal preyed on the carcasses of his huge herbivorous contemporaries; it was well adapted also by its teeth and claws to attack them when alive, and was probably their especial foe. See DINOSAUR.

Allotropy, a-lot'rō-pi, or **Allotropism** (from the Greek *allos*, "another," and *tropos*, "manner"), the property exhibited by certain substances of existing in two or more different states distinguished from each other by different properties. The most familiar case of allotropy is afforded by carbon, which exists in a number of allotropic modifications, of which charcoal, graphite, and the diamond are familiar examples. Allotropy is not exhibited by the metals to any marked degree (see, however, SILVER). Sulphur exhibits many allotropic forms, of which the following are the best known: (1) It occurs in rhombic crystals, having a sp. gr. of 2.07, melting at 235° F., and soluble in carbon disulphid; (2) in monoclinic crystals, having a sp. gr. of 1.96, melting at 243° F., and soluble in carbon disulphid; (3) in an amorphous plastic state, insoluble in carbon disulphid; (4) immediately above its melting-point it is thin, clear, and amber-colored; (5) at about 400° F. it becomes thick and dark; and (6) at about 650° F. it is again thin, but remains dark.

Ozone is a familiar allotropic form of oxygen, produced when the silent electric discharge is allowed to act upon oxygen. It is known that the molecule of oxygen contains two atoms, and that the molecule of ozone contains three atoms. This suggests that allotropy, in all cases, may be due to a similar change in the number of atoms present in a molecule; but so little is known of the ultimate structure of solids and liquids that speculation of this sort is of no great value.

Most of the non-metallic elements have allotropic modifications, and remarkable cases of allotropy are observed among chemical compounds. In the case of a compound, two states of a substance having the same chemical composition are said to be isomeric when their constituents are combined by different modes of atomic linkage; and they are said to be allotropic when the kind of atomic linkage is the same in both cases. See ISOMERISM.

Allouez, ä-lö-ā', **Claude Jean,** French Jesuit missionary: b. France, 1620; d. Indiana, 1690. He explored portions of the valley of the Mississippi and the Lake Superior region, founding the Mission of the Holy Ghost on Lake Superior in 1665, and continuing at Kaskaskia the mission established there by Marquette. See autobiography included in the 'Jesuit Relations' (1900).

Alloway, Thomas Jefferson, a Canadian surgeon: b. 1847; was graduated at the Medical Department of McGill University in 1869; spent a year in advance study in London; served three years in the British navy; and in 1894 became gynæcologist-in-chief to the Montreal General Hospital and assistant professor of gynæcology in McGill University. Dr. Alloway has made a world-wide reputation.

Al'loway, a parish of Scotland, now included in Ayr parish. Here Burns was born in 1759, and the "auld haunted kirk" near his birthplace was the scene of the dance of witches in 'Tam o' Shanter'.

Allox'an, a-lok'san, a substance produced by the action of dilute nitric acid upon uric acid, and having the formula $C_4H_2N_2O_4$. It is freely soluble in water and crystallizes in the trimetric system when a saturated solution is allowed to cool, and in monoclinic prisms when deposited by evaporation from a warm solution. It is converted into alloxantin ($C_8H_4N_4O_7$) by the action of $SnCl_2$ and other reducing agents, and into alloxanic acid ($C_4H_4N_2O_5$) by the action of the fixed alkalis. Ammonia combines with it to form murexid, a substance that was used about the middle of the 19th century for dyeing silk and wool purple and red, but which was soon displaced by the aniline colors.

Alloy' (Latin, *ad* to, and *ligare*, to bind), an intimate and apparently homogeneous mixture of different metals, usually prepared by combining the constituents in a state of fusion. From the earliest times alloys have been used for coins, implements, and works of art; but notwithstanding this fact no general and detailed theory of their nature and properties has yet been given. There is some evidence that certain metals form definite chemical combinations with one another when mixed in proper proportions, and until recently it was thought that alloys consist of certain definite compounds of this sort mixed with more or less of one or more of the constituent metals in the free state. While this may be the case, the modern tendency is strongly toward regarding alloys as solutions of metals in one another. See SOLUTION.

Some metals will not mix when melted, or will not mix in all proportions; and even when a desired mixture can be obtained in a state of fusion it not infrequently happens that a more or less complete separation of the constituent metals occurs at the moment of solidification. Attempts have therefore been made to prepare alloys by other methods. In some cases it has been found possible to obtain true alloys by mixing the constituents in a pulverized or finely-ground state, and then consolidating them under great pressure. In other cases alloys can be formed by the simultaneous electro-deposition of their constituents, or by the electro-deposition of alternate thin layers of those constituents. The success of this latter method depends upon the known fact that a metal deposited electrolytically often penetrates, to a measurable depth, the one upon which it is deposited. At the present time the alloys used in the arts are

produced almost exclusively by fusion; the various other methods that are known being confined to the laboratory.

The physical properties of alloys can seldom be inferred from those of their constituent metals. Thus speculum metal is brittle, like glass, although both copper and tin (which are its sole constituents) are ductile. A very small change in the composition of an alloy will often make a marked difference in its physical properties; and such apparently trifling circumstances as the order in which the components are added are also frequently of the greatest importance. The melting point of an alloy is usually lower than the melting points of its constituents would appear to indicate; but even this is not an invariable rule. If all possible combinations are made by fusing together a given pair (or group) of metals in all proportions, by a constant method of manipulation, it is commonly found that there is one particular alloy that has a lower melting point than any other combination of the same metals. The alloy having this property is known as the «eutectic» alloy of the metals that it contains.

By a similar systematic variation in the proportion of the components we can find out what alloy of any given metals possesses any particular physical attribute to a maximum or minimum degree. Thus Thurston has made an elaborate investigation of the strength of the copper-tin-zinc (or «kalchoid») alloys, and has shown that the strongest of these contains 57 per cent of copper, 1 per cent of tin, and 42 per cent of zinc. An alloy having 56 per cent of copper, 2 per cent of tin, and 42 per cent of zinc has nearly the same strength, however, and is more generally useful because of its greater ductility. Thurston has called the compositions, copper, 58 to 54; tin, ½ to 2½; zinc, 44 to 40, the «maximum bronzes.» Tobin bronze, containing 58.22 per cent of copper, 2.30 per cent of tin, and 39.48 of zinc, belongs in this class, and has shown a tenacity as high as 66,500 pounds per square inch of original sectional area. Like Thurston's «maximum bronze,» Tobin's alloy can be forged or rolled at a low red heat, or worked cold. When cold-rolled its tensile strength may be raised to 104,000 pounds per square inch without any serious corresponding loss of ductility.

Properly speaking, neither Tobin's alloy nor Thurston's is a «bronze.» Strictly, bronze is an alloy of copper and tin, and brass is an alloy of copper and zinc; but in practice small amounts of zinc are often added to the bronzes, and small amounts of tin to the brasses, so that there is no longer any hard and fast line between the two.

Guillaume, of the International Bureau of Weights and Measures, has recently obtained some remarkable results with alloys of nickel and iron, which afford excellent illustrations of the fact that little can be safely inferred concerning the properties of an alloy from those of its constituents. Thus it was found that an alloy containing about 25 per cent of nickel is practically non-magnetic, being as insensible to the action of a magnet as copper, although iron and nickel are the two most magnetic substances known. Alloys containing 24 per cent (or less) of nickel are magnetically irreversible, in the sense that they do not lose and regain their magnetism at the same temperature. Thus alloy containing 24 per cent of nickel loses its magnetism at a cherry-red heat, and does not become magnetic again until it has been exposed to a temperature in the neighborhood of 32° F. Equally remarkable results were obtained in studying the coefficients of expansion of nickel-steel. It was found, for example, that an alloy containing 36 per cent of nickel has a coefficient of expansion which is almost negligible, even in refined scientific work. This particular alloy has been called «invar,» because its length is so nearly invariable under the influence of heat. Nearly every pendulum clock that is made in Germany to-day has its pendulum rod made of invar, except possibly some of the cheapest grades. (For further information concerning nickel-steel alloys see the 'Engineering Magazine,' October 1901, page 79; and the 'American Machinist,' 8 Jan. 1903, page 67.) The general composition of some of the commoner alloys is given in the following table, but it should be remembered that these proportions (which are expressed in percentages by weight) are variable in practice to a certain extent:

COMPOSITION OF COMMON ALLOYS.

Name	Copper	Tin	Zinc	Lead	Other Metals
Gun metal	91	9			
Bell metal	75	25			
Phosphor bronze	92½	7			½ phosphor.
Aluminum bronze	90				10 aluminum
Valve metal	88	10	2		
Brass (common)	66⅔		33⅓		
Muntz metal	60		40		
Delta metal	56		42		2 iron
Brazing metal (soft)	50	12½	37½		
Brazing metal (medium)	50		50		
Brazing metal (hard)	75		25		
German silver	60		20		20 nickel
Speculum metal	67	33			
Common solder		50		50	
Fine solder		66⅔		33⅓	
Babbitt metal	3	89			8 antimony
Pewter		80		20	
Britannia metal		90			10 antimony
Type metal				80	20 antimony
Aich metal	59		39		2 iron
Dutch metal	85		15		
Newton's metal		19		31	50 bismuth
Rose's metal		25		25	50 bismuth

Both the gold and the silver coins of the United States contain 90 per cent of pure metal. The silver coins contain 10 per cent of copper, and the gold coins contain 10 per cent of copper alloy, not more than one tenth of which can be silver.

(See Thurston's 'Brasses, Bronzes, and Other Alloys,' New York 1893, for valuable and extensive information on alloys containing copper, zinc, lead, and tin. For alloys of nearly constant electrical resistance see RESISTANCE, ELECTRICAL.

All Saints' Bay, or **Bahia de Todos os Santos,** a bay on the coast of the State of Bahia in Brazil, forming an excellent natural harbor. On its east side stands the port of Bahia. The neighboring country is well adapted for the cultivation of rice and sugar-cane.

All Saints' Day, a festival instituted by Pope Boniface IV., early in the 7th century, on the occasion of his transforming the Roman

heathen Pantheon into a Christian temple or church, and consecrating it to the Virgin Mary and all the martyrs. It is kept by the Roman Catholic Church, and by churches in communion with the Church of England on 1 November, and by the Greek Church on the Sunday after Whitsunday. It is designed, as its name implies, to honor all departed saints, and was formerly called All-hallows. In many American churches a custom has grown up of making the Sunday nearest 1 November the occasion of a service in memory of those who have died during the year.

All Sorts and Conditions of Men, a novel by Sir Walter Besant. The famous People's Palace of East London had its origin in this story; and because of it Besant was knighted. The story concerns chiefly two characters,—the very wealthy orphan, Angela Messenger, and Harry Goslett, ward of Lord Joscelyn. Miss Messenger, after graduating with honors at Newnham, resolves to examine into the condition of the people of Stepney Green, in the Whitechapel region, where she owns great possessions. To indicate to the working women of East London a way of escape from the meanness, misery, and poverty of their lives, she sets up among them a co-operative dressmaking establishment, she herself living with her work-girls. Her goodness and wealth bring happiness to many. The book ends with the opening of the People's Palace, and with the heroine's marriage to Harry Goslett.

All Souls' College, Oxford, was founded in 1437 by Henry Chichele, archbishop of Canterbury, for a warden, 40 fellows, 2 chaplains, and clerks. The present arrangement of fellowships was fixed by statutes which came into operation in 1882.

All Souls' Day, the day on which the Catholic Church commemorates all the faithful deceased. It was first enjoined in the 11th century by Odile, Abbot of Cluny, on the monastic order of which he was the head, and soon afterward came to be adopted by the Church generally. It is observed on 2 November.

Allspice, or PIMENTA, is the dried berry of a West Indian species of myrtle (*Myrtus pimenta*) which grows to the height of 20 feet and upward, and has somewhat oval leaves about 4 inches long, of a deep shining green color, and numerous branches of white flowers, each with four small petals. This tree is by some botanists referred to the genus *Eugenia* and called *E. pimenta*. Others again constitute a genus *Pimenta*, the present species being *P. officinalis*. In the whole vegetable creation there is scarcely any tree more beautiful or more fragrant than a young pimenta-tree about the month of July. Branched on all sides, richly clad with deep green leaves, which are relieved by an exuberance of white and richly aromatic flowers, it attracts the notice of all who approach it. About the month of September, and not long after the blossoms have fallen, the berries are in a fit state to be gathered. At this time, though not quite ripe, they are full grown and about the size of peppercorns. They are gathered by hand. The berries are spread in the sun to be dried, an operation that requires great care, from the necessity of keeping them entirely free from moisture. By the drying they lose their green color and become a reddish brown; the process is known to be complete by their change of color and by the rattling of the seeds within the berries. They are then packed into bags or hogsheads for the market. When the berries are quite ripe they are of a dark purple color and filled with a sweet pulp. Pimenta is thought to resemble in flavor a mixture of cinnamon, nutmegs, and cloves, whence it has obtained the name allspice. For its use in medicine see CONDIMENTS.

Allston, Margaret. See BERGENGREN, ANNA; FARQUHAR, ANNA.

Allston, Theodosia Burr. See BURR, THEODOSIA.

Allston, Washington, American painter and author: b. Waccamaw, S. C., 5 Nov. 1779; d. Cambridge, Mass., 9 July 1843. He graduated at Harvard, 1800; studied art in Europe, 1801–9; resided in England, 1811–18; and opened a studio in Boston, Mass., 1818. His painting 'The Dead Man Revived' was awarded a prize of 200 guineas. Other well-known works are, 'The Prophet Jeremiah'; 'Spanish Girl'; 'Spalatro's Vision of the Bloody Hand'; 'Belshazzar's Feast,' and portraits of Benjamin West, Coleridge, and himself. He has a high reputation as a colorist and has been called the "American Titian." His writings comprise, 'The Sylphs of the Seasons' (1813); 'Monaldi,' a romance of Italian life (1841), and 'Lectures on Art, and Poems' (1850). See Ware's 'Lectures on the Works and Genius of W. Allston' (1852), and the 'Life' by Flagg (1892).

All's Well that Ends Well, a play by Shakespeare, the story of which came to the poet from Boccaccio through Paynter's 'Palace of Pleasure.' It tells how Helena de Narbon forced her love on a handsome and proud young French nobleman, Bertram de Rousillon, with whom she had been brought up from childhood. It is a tale of husband-catching by a curious kind of trick; but Shakespeare endows Helena with such virtues that we excuse and applaud her action. Hence all's well that ends well. She heals the king, asks for and accepts Bertram as her reward, and is married. But the proud boy flies to the Florentine wars on his wedding-day, leaving his marriage unconsummated. Helena returns sorrowfully to Rousillon, and finds there a letter from her husband to the effect that when she gets his ring upon her finger and shows him a child begotten of his body, then he will acknowledge her as his wife. She undertakes to outwit him and reclaim him, and leaving Rousillon on pretense of a pilgrimage she has it reported that she is dead. In reality she goes to Italy and becomes Bertram's wife in fact, and not mere name, by the substitution of herself for the pretty Diana with whom he has an assignation arranged. There is an entanglement of petty accidents and incidents connected with an exchange of rings, etc. But finally Helena makes good before the king her claim of having fulfilled Bertram's conditions; and she having vowed obedience, he takes her to his heart. Shakespeare has followed his original closely, but the Countess, the Clown Lafen, and Parolles are creations of his own.

Alluvion, the legal designation of land gained from the water by gradual changes in the shore line. In English law the form of the word generally used is alluvion, and in Scotch law alluvio. In both of these the enactment is, that if an «eyott,» or little island, arise in a river midway between the two banks, it belongs in common to the proprietors on the opposite banks; but if it arise nearer one side it then belongs to the proprietor whose lands it there adjoins. If a sudden inundation cut off part of a proprietor's land, or transfer the materials to that of another, he shall be recompensed by obtaining what the river has deposited in another place; but if the process be a gradual one there is no redress. In the United States the proprietor of the bank increased by alluvion may lawfully claim the addition, this being regarded as the equivalent for the loss he may sustain from the encroachment of the water upon his land. Sea-weed which is thrown upon a beach, as partaking of the nature of alluvion, belongs to the owner of the beach. 2 Johns. N. Y. 322. But sea-weed below low-water mark on the bed of a navigable river belongs to the public. 9 Conn. 38. See ACCRETION; AVULSION.

Alluvium, a word formerly applied to the gravel, mud, sand, etc., deposited by water subsequently to the Noachian deluge. It was opposed to diluvium, supposed to be laid down by the deluge itself, or, in the opinion of others, by some great wave or series of waves originated by the sudden upheaval of large tracts of land or some other potent causes, different from the comparatively tranquil action of water which goes on day by day.

Now alluvium is especially employed to designate the transported matter laid down by fresh water during the Pleistocene and Recent periods. Thus it indicates partly a process of mechanical operation and partly a date or period. It should not be forgotten that the former has gone on through all bygone geological ages and has not been confined to any one time. Many of the hardest and most compact rocks were once loosely cohering débris laid down by water. The most typical example of alluvium may be seen in the deltas of the Nile, Ganges, Mississippi, and many other rivers. Some rivers have alluviums of different ages on the slopes down into their valleys. The more modern of these belong to the Recent period, as do the organic or other remains which they contain, while the older (as those of the Somme, Thames, Ouse, etc.), which are of Pleistocene age, enclose more or less rudely chipped flint implements, with the remains of mammals either locally or everywhere extinct. Though in many cases it is possible clearly to separate alluviums of different ages, yet the tendency of each new one is to tear up, redistribute, and confound all its predecessors.

Volcanic alluvium is sand, ashes, etc., which, after being emitted from a volcano, come under the action of water and are by it redeposited, as was the case with the materials which entered and filled the interior of houses at Pompeii.

Marine alluvium is alluvium produced by inundations of the sea, such as those which have from time to time overflowed the eastern coast of India.

Al'lyl, in chemistry, the radical CH_2:CH.CH_2, or C_3H_5. (The isomeric radical CH_3.CH:CH is called propenyl.) Allyl forms many compounds, of which the most important is perhaps allyl alcohol, C_3H_5.OH, which is produced when glycerin is distilled with oxalic acid.

Al'lyn, Robert, American clergyman and educator: b. Ledyard, Conn., 25 Jan. 1817; d. 7 Jan. 1894. Educated at Wesleyan University, Middletown, Conn., he entered the Methodist Episcopal ministry. He was appointed commissioner of public instruction for Rhode Island in 1854, and served three terms in the legislature of that State. He was president of the Wesleyan Female College, Cincinnati, Ohio, 1859–63, and of McKendree College, Illinois, 1863–73.

Al-Mamun, mä-mōn', a caliph of the Abasside dynasty, son of Harun al-Rashid: b. 786; d. 833. Under him Bagdad became a great centre of art and science.

Alma, Mich., a town in Gratiot County, 38 m. W. of Saginaw, on Pine River, and Ann Arbor and Père Marquette R.R.'s; founded 1854; inc. 1872. It manufactures flour, lumber, and beet sugar; has water works and electric lighting. It contains Alma College (q.v.), and Alma Sanitarium, widely reputed. It has one-year mayoralty and a council of six. Pop. (1900) 2,047.

Alma, a river in the Crimea, rising at the foot of the Tchadir Dagh, and flowing W. into the Bay of Kalamita, about half way between Eupatoria and Sebastopol. On the steep banks of the stream, through the channel of which the British troops waded amid a shower of bullets, a brilliant victory was won 20 Sept. 1854, by the allied armies of England, France, and Turkey, led by Lord Raglan and Marshal St. Arnaud, over the Russian army commanded by Prince Menschikoff. It was the first battle of the Crimean war.

Almack's, the name formerly given to certain assembly-rooms in King Street, St. James's, London, derived from Almack, a tavern-keeper, by whom they were built, and whose real name is said to have been M'Call, and transformed into Almack by reversing the syllables. The premises are now known as «Willis's Rooms.» First opened 20 Feb. 1765, they soon became famous for the extreme exclusiveness displayed by the lady patronesses in regard to the admission of applicants for tickets. These fair arbiters composed a board of six, which held its sittings every Monday evening during the London season, and issued those fiats which were supposed to affect so conclusively the claims of the received or rejected applicant, as the case might be, to occupy the upper circles in the fashionable world. To have danced at Almack's became almost proverbial as indicative of exalted social position. The name was also given to a gambling club established by the same Almack in 1763, to which such men as Charles James Fox, William Pitt, and Gibbon belonged.

Alma College, a co-educational institution in Alma, Mich., organized 1887 under Presbyterian control; reported in 1899: Professors and instructors, 20; students, 254; volumes in library, 17,000; grounds and buildings valued at $60,000; productive funds, $220,000; income $155,000; graduates, 213.

Almada, a town of Portugal, in the province of Estremadura, on the left bank of the estuary of the Tagus, opposite Lisbon. It is built upon a height, in a well-cultivated country, and has long been celebrated for its figs. It has a strong castle on a rock, a hospital for British seamen, a Latin school, several depots for wine, and a mineral spring. Pop. 7,000.

Almaden, Cal., a town in Santa Clara County, noted for its mines of mercury and its mineral springs. It was named after the Spanish town mentioned below on account of its four quicksilver mines, the New Almaden, Providence, Enriquita, and Guadelupe. Large quantities of mercury have been distilled from the ore (cinnabar), and the existence of this deposit has been of immense benefit to the Pacific States. Pop (1900) 1,599.

Almaden, or **Almaden del Azogue** (mine of quicksilver), a town in Spain 50 m. S.W. of the town of Ciudad-Real in the province of the same name. It is widely known for its rich quicksilver mines which have been worked for centuries, and in which some 4,000 miners are employed. Since 1645 the mines have been the property of the Crown. The town contains a ruined castle of the Moorish period and a school of mines. Pop. (1900) 7,459.

Almagest. The usual appellation of the 'Syntaxis' of Ptolemy, derived from an Arabic term signifying "the greatest." This celebrated work was written about the middle of the 2d century of our era, and comprises an exposition of the ancient system of astronomy, so elaborate and thorough as to have made it a standard for 13 centuries. It contains the most ancient known catalogue of the stars, with observations of the motion of the planets, and determinations of their periods. Several editions, one in Greek and others in Latin, appeared in Europe between 1500 and 1700. The most recent accessible edition is that of the Abbe Halma, which is in Greek and French (2 Vols. Paris 1814–15).

Almagro, Diego, one of the companions of Pizarro in the conquest of Peru, was a foundling, and the exact date of his birth is not known; d. 1538. He engaged with Pizarro and Fernando de Lugue in the long and arduous expedition in which they made the discovery of Peru (1524–27), took part in the conquest of the country and the treacherous murder of Atahualpa (1533), and after frequent disputes with Pizarro about their respective shares in their conquests he led an expedition against Chile, of which he was appointed governor. Having failed to conquer his new province he returned to find Cuzco in possession of the Indians, who had expelled Pizarro. He reconquered it and made himself governor, but, Pizarro returning, a struggle took place between the two parties in which Almagro was finally overcome, taken prisoner, strangled, and afterward beheaded. He was avenged by his son, who raised an insurrection in which Pizarro was assassinated in 1541. The younger Almagro was put to death in 1542 by De Castro, the new viceroy of Peru. Almagro showed himself, like most of the Spaniards engaged in the conquest of the New World, capable of enduring great privations with heroic constancy, and of effecting wonderful achievements by undaunted valor, but cruel, rapacious, and unscrupulous in success.
